CROI FOUNDATION

The CROI Foundation operates exclusively for the charitable and educational purpose of organizing, promoting, and presenting the Conference on Retroviruses and Opportunistic Infections (CROI).

Roles and Responsibilities of the CROI Foundation Board of Directors

- Works closely with the CROI Scientific Program Committee (CROI PC) and the CROI Secretariat to accomplish the mission of CROI
- Approves nominations for members of the CROI PC and the CROI PC Chair and Vice Chairs
- Ensures that the CROI PC is responsible for the scientific program content of CROI
- Enters into and oversees the partner agreement with the CROI Secretariat
- Has the sole and absolute discretion to veto any policies, procedures, or actions taken or proposed to be taken by the CROI PC or the CROI Secretariat that would pose a substantial risk of preventing the Foundation at any time from qualifying or continuing to qualify as a 501(c)(3) organization or that might cause the loss of such qualification
- Oversees the long-term financial and administrative integrity of CROI

Composition of the CROI Foundation Board of Directors

The Board of Directors comprises current and previous CROI Chairs and Vice Chairs and selected members of the CROI PC.

CROI Foundation Board Members

Constance A. Benson, MD, President
University of California San Diego
San Diego, CA, US

John M. Coffin, PhD, Secretary-Treasurer
Tufts University
Boston, MA, US

Elaine J. Abrams, MD
International Center for AIDS Care and Treatment Programs
Columbia University
New York, NY, US

Susan P. Buchbinder, MD
San Francisco Department of Public Health
University of California San Francisco
San Francisco, CA, US

Judith S. Currier, MD, MsC
University of California Los Angeles
Los Angeles, CA, US

Kevin M. De Cock, MD
Centers for Disease Control and Prevention
Nairobi, Kenya

Scott M. Hammer, MD
Columbia University Medical Center/New York–Presbyterian Hospital
New York, NY, US

John W. Mellors, MD
University of Pittsburgh
Pittsburgh, PA, US

Julie M. Overbaugh, PhD
Fred Hutchinson Cancer Research Center
Seattle, WA, US

Robert T. Schooley, MD
University of California San Diego
San Diego, CA, US

Mario Stevenson, PhD
University of Miami
Miami, FL, US

IAS–USA

The International Antiviral Society–USA is a 501(c)(3) not-for-profit professional education organization. The IAS–USA serves as the Conference Secretariat for CROI.

The mission of the IAS–USA is to improve the treatment, care, and quality of life for people with HIV, hepatitis C virus, or other viral infections through high-quality, relevant, balanced, and needs-oriented education and information for practitioners and scientists who are actively involved in medical care and research.

Executive Director: Donna M. Jacobsen

Address: 425 California Street, Suite 1450
San Francisco, CA 94104-2120

Phone: 415-544-9400

CROI 2015 PROGRAM COMMITTEE

The Scientific Program Committee (PC) is a team of experts in their given field who volunteer to organize the scientific program for CROI. Members are selected based on their area of scientific expertise and their commitment to the mission of the conference. Initial terms are 3 years; subsequent terms are based on previous participation and interest level. Members are nominated by the PC and approved by the CROI Foundation Board of Directors. The "goodwill ambassadors" of CROI, PC members are also responsible for identifying topics and speakers that will ensure innovative programming; strategic planning; abstract review and program development; and organizing, conducting, and convening workshops, symposia, and special sessions.

Scientific Program Committee

Scott M. Hammer, MD
CROI 2015 Chair
Columbia University Medical Center/New York–Presbyterian Hospital
New York, NY, US

Julie M. Overbaugh, PhD
CROI 2015 Vice Chair
Fred Hutchinson Cancer Research Center
Seattle, WA, US

Susan P. Buchbinder, MD
CROI 2015 Vice Chair
San Francisco Department of Public Health
University of California San Francisco
San Francisco, CA, US

Elaine J. Abrams, MD
ICAP at Columbia University
New York, NY, US

Galit Alter, PhD

COMMERCIAL SUPPORT

The Conference on Retroviruses and Opportunistic Infections (CROI) is largely supported by the registration fees of participants. In addition, the organizers seek grants from commercial companies, particularly from companies with competing products. These companies have no input in or control over the selection of faculty or content of the presentations.

CROI 2015 has, to date, received grant support commitments from the following commercial companies:

Platinum

Gilead Sciences, Inc

Merck & Co, Inc

ViiV Healthcare

Gold

Bristol-Myers Squibb

Janssen Therapeutics, Division of Janssen Products, LP

Silver

AbbVie

Additional support has been provided by Mylan, Inc

CONFERENCE SCHEDULE OVERVIEW

	Monday, February 23, 2015	Tuesday, February 24, 2015	Wednesday, February 25, 2015	Thursday, February 26, 2015
8:30 AM		**Plenary:** PrEP for HIV Prevention: What We Know and What We Need to Know for Implementation ***4AB Auditorium***	**Plenary:** Preventing Pediatric HIV and Managing HIV-Infected Children: Where Are We Now and Where Are We Going? ***4AB Auditorium***	**Plenary:** Cardiovascular Disease in HIV Patients: An Emerging Paradigm and Call to Action ***4AB Auditorium***
9:00 AM	**Workshop for New Investigators and Trainees** 9:00 AM to 12:30 PM ***Room 6E***	**Plenary:** Specific HIV Integration Sites Linked to Clonal Expansion and Persistence of Cells ***4AB Auditorium***	**Plenary:** Directing Chronic Virus Infection Through Viral Regulation of Innate Immune Defenses ***4AB Auditorium***	**Plenary:** The Price of Selling Sex: HIV Among Female Sex Workers—The Context and the Public Health Response ***4AB Auditorium***
9:30 AM				
10:00 AM		**ORAL ABSTRACT CONCURRENT SESSIONS** 10:00 AM to 12:15 PM **O-1:** Preventing HIV and HSV-2: What Will It Take? ***Room 6AB*** **O-2:** Prevention, Diagnosis, and Treatment of Pediatric HIV Infection ***Room 613*** **O-3:** Cellular Dynamics, Sensing, and Viral Restriction ***Room 615*** **O-4:** New Discoveries in HIV Pathogenesis ***Room 6D***	**ORAL ABSTRACT CONCURRENT SESSIONS** 10:00 AM to 12:15 PM **O-6:** Intracellular and Clinical Pharmacology, Drug Interactions, and Adherence ***Room 615*** **O-7:** KS and Cervical/Anal Dysplasia: Tale of 2 Tumors and TB and Other OIs ***Room 613*** **O-8:** Factors Affecting HIV Care and Outcome: Global Perspective ***Room 6E*** **O-9:** New Insights Into HIV Persistence, Latency Reversal, and Viremia Rebound ***Room 6D***	**ORAL ABSTRACT CONCURRENT SESSIONS** 10:00 AM to 12:15 PM **O-11:** Cardiovascular, Bone, and Kidney Health ***Room 6C*** **O-12:** Curing HCV: Mission Accomplished ***Room 6AB*** **O-13:** Reaching Populations: Demonstrating Impact ***Room 6D*** **O-14:** Immune Mechanisms: The Road to Protection ***Room 613***
12:15 PM		**LUNCH** 12:15 PM to 1:30 PM	**LUNCH** 12:15 PM to 1:30 PM	**LUNCH** 12:15 PM to 1:30 PM
12:30 PM	**LUNCH** 12:30 PM to 1:00 PM			
1:00 PM	**Martin Delaney Presentation** 1:00 PM to 2:00 PM **How to End the HIV Epidemic: Community Perspectives** ***Room 6E***			
1:30 PM		**THEMED DISCUSSION CONCURRENT SESSIONS** 1:30 PM to 2:30 PM **TD-B:** Next Generation of Next-Generation Sequencing ***Room 615*** **TD-C:** HIV/CMV Interactions in Transmission and Pathogenesis ***Room 613*** **TD-F:** Leaky Latency ***Room 6D*** **TD-Q:** Fat Without Borders: Metabolic Complications in Resource-Limited Settings ***Room 6AB*** **TD-S:** Hormonal Contraceptives: Enduring Controversy ***Room 6C*** **TD-Y:** Circumcision: Evolving Knowledge and Practice ***Room 6E***	**THEMED DISCUSSION CONCURRENT SESSIONS** 1:30 PM to 2:30 PM **TD-A:** Interferon: Triggers and Effectors ***Room 615*** **TD-H:** New Technologies in Assessing Drug Interactions and Systemic and Intracellular Pharmacology ***Room 613*** **TD-O:** Cancers in Young and Old, and Lung Cancer in HIV ***Room 6D*** **TD-R:** Cryptococcal Meningitis: Host Response, Treatment, and Outcomes ***Room 6E*** **TD-W:** Serosorting and Seroadaptive Behavior: What's Your Position? ***Room 6AB*** **TD-Z:** Economic Implications of ART ***Room 6C***	**THEMED DISCUSSION CONCURRENT SESSIONS** 1:30 PM to 2:30 PM **TD-M:** Identifying Recent Infections: Issues of False Recency ***Room 615*** **TD-N:** Next-Generation HCV Therapeutics: From Clinical Trials to the Clinic ***Room 6AB*** **TD-P:** Cardiovascular Risk Prediction: Can We Do Better? ***Room 6E*** **TD-T:** Keys to the Kingdom: Viral Suppression in Pregnant and Postpartum Women ***Room 6D*** **TD-V:** PEP: Remember Me? ***Room 6C***
2:00 PM				

2:30 PM	**CONCURRENT WORKSHOPS** 2:30 PM to 4:30 PM Clinical Trial Design and Analysis ***Room 6E*** Frontiers in Laboratory Science ***Room 6D*** Hepatitis C Care in the Interferon-Free Era ***Room 613***	**POSTER SESSIONS** 2:30 PM to 4:00 PM ***Poster Hall***	**POSTER SESSIONS** 2:30 PM to 4:00 PM ***Poster Hall***	**POSTER SESSIONS** 2:30 PM to 4:00 PM ***Poster Hall***
4:00 PM		**CONCURRENT SYMPOSIA** 4:00 PM to 6:00 PM **S-1:** Harnessing Antibodies for Prevention and Therapeutics ***Room 6C*** **S-2:** Current Issues in HIV-Related Malignancies ***Room 6D*** **S-3:** Current Imperatives in HIV Prevention and Treatment ***Room 6AB***	**CONCURRENT SYMPOSIA** 4:00 PM to 6:00 PM **S-4:** Making Sense of Sensing: Innate Immunity and HIV Infection ***Room 613*** **S-5:** Advancing HIV Prevention: Lessons From Biology, Medicine, and Public Health Law ***Room 6D*** **S-6:** Tuberculosis: Magic Bullets and Moving Targets ***Room 6E***	**CONCURRENT SYMPOSIA** 4:00 PM to 6:00 PM **S-7:** From Pathways to Paradigms: Applications of Systems Biology to HIV/Host Interactions ***Room 613*** **S-8:** Scale-Up of Interventions ***Room 6D*** **S-9:** HCV: New Frontiers and Controversies ***Room 6E***
4:30 PM				
5:00 PM	**Opening Session** 5:00 PM to 7:00 PM **Bernard Fields Lecture:** Hepatitis C: Light at the End of the Tunnel **N'Galy-Mann Lecture:** Antiretroviral Therapy: Past, Present, and Future ***4AB Auditorium***	**ORAL ABSTRACT SESSION** **O-5:** NeuroAIDS Pathogenesis and Antiretroviral Therapy ***Room 613***	**ORAL ABSTRACT SESSION** **O-10:** New Antiretroviral Agents, Strategies, and HIV Drug Resistance ***Room 6C***	
6:00 PM				
6:30 PM		**SPECIAL SESSION** 6:30 PM to 7:30 PM Ebola Virus Disease: Responding to the Challenge ***Room 6E***		
7:00 PM	**Welcome Reception** Nordstrom Downtown Seattle 500 Pine Street (Cross street 5th Ave) Seattle, WA 98101

CONTINUING MEDICAL EDUCATION

Accreditation Statement

The International Antiviral Society–USA (IAS–USA) is accredited by the Accreditation Council for Continuing Medical Education (ACCME) to provide continuing medical education (CME) for physicians.

The IAS–USA designates this live activity for a maximum of **28 AMA PRA Category 1 Credits™**. Physicians should claim only the credit commensurate with the extent of their participation in the activity.

Since 2006, the IAS–USA has held Accreditation with Commendation. In so doing, the IAS–USA belongs to an elite group of organizations in the United States that have been awarded this prestigious status, which, in the words of the ACCME, is "reserved for programs that are truly exceptional."

Objectives

After participating in CROI 2015, learners will be able to:

- Describe current basic science research on the pathogenesis of HIV and on advances toward a cure
- Discuss the most recent findings from clinical trials in the field of HIV and the implications of these data for state-of-the-art treatment strategies
- Review current epidemiologic data on the prevalence of HIV infection, transmission, treatment, and linkage to and retention in care in populations worldwide, and discuss the implications of these data for public-health program planning

Statement of Need

Since HIV was identified, the scientific response to the global pandemic has been a coordinated effort among basic researchers, clinical investigators, health care providers, epidemiologists, and community leaders to move information and potential treatment options from research to clinical trials and out to affected communities as quickly as possible. CROI was founded in 1993 by researchers working in the field of HIV/AIDS and its complications, as a science-focused forum for exchanging current research findings among their international peers. CROI continues to focus on scientific exchange, providing an environment in which basic science researchers, translational researchers, clinical investigators, epidemiologists, and public health experts meet to present and discuss the latest research into different facets of HIV and its complications.

CME Credit Information

Physicians (MD, DO, and international equivalents) are eligible to receive CME credit for participation in CROI 2015. Other practitioners and clinicians can receive a Certificate of Participation verifying their attendance, as required by the American Medical Association (AMA).

Claiming CME Credits or a Certificate of Participation

During the conference, daily evaluations will be e-mailed to all CROI participants to the e-mail account they used to register for the conference. On Thursday, February 26, 2015, all CROI participants will receive a final e-mail that will contain their registration confirmation number and a link to the overall CROI evaluation. To obtain CME credits or a Certificate of Participation for CROI, this final evaluation must be completed by Tuesday, March 31, 2015. Once the evaluation is submitted, participants will receive the link to claim and print their certificate.

To determine the number of CME credits or hours that you can claim, calculate your time spent attending the conference, including plenary sessions, symposia, themed discussions, etc. For example, if you attended 2 plenary talks (8:30 AM to 9:30 AM), a themed discussion (1:30 PM to 2:30 PM), and a symposium (4:00 PM to 6:00 PM), you would have a total of 4 hours to apply toward CME credits for that day. At the end of CROI, please add the total hours you attended for your certificate. You may claim a maximum of **28 AMA PRA Category 1 Credits™** for this activity.

A CME hour worksheet can be found here: http://www.croiconference.org/sites/default/files/uploads/croi2015_cme_worksheet.pdf.

Faculty Financial Disclosure

It is the policy of the IAS–USA to ensure balance, independence, objectivity, and scientific rigor in all its educational activities. All faculty members (speakers, presenters, etc) participating in IAS–USA-sponsored activities are required to disclose to the program audience any financial interests within the past 12 months that could be perceived to influence, or give the appearance of potentially influencing, the written or oral presentation. (The ACCME defines a financial interest as an interest in any amount.) The information is intended to make the IAS–USA audience aware of author and contributor interests and commitments with commercial companies or other entities, enabling the audience members to form their own judgments about such associations.

Each author or contributor is required to complete this financial disclosure declaration. In accordance with IAS–USA policy, the IAS–USA will identify and resolve ahead of time any possible conflicts of interest that may influence CME activities with regard to exposition or conclusion. Disclosure information will be included with the Program and Abstracts eBook on the web.

Drug and Product Disclaimer

This activity may contain information about the investigational uses of drugs or products that are not approved by the US Food and Drug Administration. Please consult full prescribing information before using any medication or product mentioned in this activity.

GENERAL INFORMATION

Overview

The 2015 Conference on Retroviruses and Opportunistic Infections (CROI) will take place at the Washington State Convention Center in Seattle, WA, from February 23 to February 26, 2015. CROI was established in 1993 to provide a forum for basic scientists and clinical investigators to present, discuss, and critique their investigations into the epidemiology and biology of human retroviruses and associated diseases. The synergy of basic science and clinical investigation has been a major contributor to the success of the meeting. CROI is the preeminent HIV research meeting in the world and attracts more than 4000 HIV and AIDS research leaders internationally. The goal of the conference is to help researchers translate their laboratory and clinical findings into tangible progress against the HIV pandemic. CROI has facilitated the presentation of important discoveries in the field, thereby accelerating progress in HIV and AIDS research.

Americans with Disabilities Act

CROI 2015 endeavors to comply fully with the legal requirements of the Americans with Disabilities Act (ADA). If you require assistance on-site, please visit the Seattle Visitor Center and Concierge Services in the Upper Pike Street Lobby during the conference.

Ebola Precautions

Attendees who have recently returned from an Ebola-prevalent area are expected to follow the guidance of their institutions, local health departments, or the Centers for Disease Control and Prevention (CDC) as applicable with respect to monitoring and travel. CDC guidance can be found online: http://www.cdc.gov/vhf/ebola/exposure/monitoring-and-movement-of-persons-with-exposure.html.

Welcome Reception

All registered CROI attendees are invited to join us for a Welcome Reception immediately following the Opening Reception on February 23, 2015. This will be a private event hosted at Nordstrom's Flagship store in Downtown Seattle just a minutes walk from the Convention Center at Sixth and Pine Streets (enter using the Sixth Avenue entrance).

This unique Welcome Reception will offer attendees the opportunity to network with colleagues and experience a private shopping environment while enjoying passed hors d'oeuvres and beverages in a beautiful and unique setting.

Please join us for this exclusive event!

Meals

Morning coffee and light continental breakfast will be available to conference registrants from 9:30 AM to 10:00 AM, Tuesday, Wednesday, and Thursday, on the 6th floor. An afternoon snack break will be available at 2:30 PM in the Poster Hall and before the special session on Tuesday evening. Attendees are on their own for lunch each day. Below is a list of food service options located in the Convention Center or within a short walking distance.

At the Convention Center

820 Pike Street – Pan Asian Cuisine
Crêpes Voilá
Cyber Dogs – Internet Café
Espresso Caffé Dior
Goldberg's Deli
Subway Sandwiches
Taco Del Mar
The Juicy Café
Tully's Coffee
Wild Rye Café Bakery

Within 4 Blocks of the Convention Center

Benihana
Blueacre Seafood
Blue C Sushi
Daily Grill
Dragonfish Asian Cafe
FareStart
FOX Sports Grill
Gameworks
Gordon Biersch Brewery Restaurant
Il Fornaio
MOD Superfast Pizza
Morton's The Steakhouse
Ebar (Nordstrom Downtown Seattle)
Marketplace Café (Nordstrom Downtown Seattle)
The Grill (Nordstrom Downtown Seattle)
NYC Hyatt Deli Market
P.F. Chang's China Bistro – Seattle
Palomino
Pike Place Chowder – Pacific Place
Potbelly Sandwich Shop
RN74
Rock Bottom Restaurant & Brewery
Ruth's Chris Steak House
Soup's On!
Starbucks Coffee Company
Sullivan's Steakhouse
Tango Restaurant & Lounge
Tap House Grill
Thai Ginger
The Capital Grille
The Cheesecake Factory
The Elephant and Castle Pub & Restaurant
Toss'd Custom Salads
Urbane Northwest (Hyatt at Olive 8)

Overflow Accommodations for Session Rooms

The 4AB Auditorium is the designated overflow area. Headsets and up to 4 screens will provide live audio and video feed throughout the conference.

USB Flash Drive

Each participant is supplied a USB flash drive at badge pickup with a copy of the eAbstract book. The Program at a Glance and Program and Abstracts eBook are also available online to be loaded onto the USB flash drive. Downloads can be completed at the Cyber Cafe or directly from the conference website.

Website

For additional information about the conference please visit the website at www.CROIconference.org.

Webcasts and Podcasts

Plenaries, symposia, scientific overviews, oral abstract sessions, and themed discussions will be webcast and podcast. Webcasts are also available as streaming video for the Apple iPad and iPhone.

Visit www.CROIconference.org or www.CROIwebcasts.org to access the CROI 2015 webcasts and podcasts. Webcasts will be available within 24 hours of the end of the relevant session.

Mobile App

CROI 2015 has a mobile App to enhance your conference experience. The App enables you to schedule sessions, view abstracts, e-mail session notes, receive announcements, and more. Search "CROI 2015" in your mobile device App store, and download the conference App. The mobile App supports iOS and Android devices. Access is restricted to registered attendees only. Your log-in information and password will be provided to you on site with your registration materials.

Wi-Fi Access at the Conference

Complimentary Wi-Fi access is provided at the Washington State Convention Center. Network information is as follows:

Network name: CROI 2015

Password: iasusa2015

Badges

Badge pickup will be available at the registration lobby; please bring government-issued photo identification that clearly shows your name. You must wear your name badge to gain entry to all official meeting activities, including the poster sessions. **DO NOT LOSE YOUR BADGE. Unfortunately, payment of an additional registration fee ($730) will be required to replace a lost badge.** Also, if you notice that your affiliation or the affiliations of other attendees are incorrect, please inform conference staff in the office of the Conference Secretariat.

Child Care

Children are not permitted entry into any meeting room, including the poster area. If you should require child care, please contact the concierge of your hotel or the Visitor Information Center on Level One at the Washington State Convention Center.

Conference Etiquette

Please ensure all cell phones and pagers are off or are placed in SILENT mode. No flash photography is permitted in session rooms.

CONFERENCE SERVICES AT THE WASHINGTON STATE CONVENTION CENTER

Services	Location	Hours	Notes
Seattle Visitor Center and Concierge Services	Upper Pike Street Lobby Level 1	Monday to Friday 9:00 AM–5:00 PM	Full-service concierge assistance, including maps, guides, tickets, restaurant reservations, tours, ground transportation, and personal services

Use of this room is on a first-come, first-served basis.
New Mother's Room	Room 416 Level 4	Sunday 3:00 PM–6:00 PM, Monday 7:00 AM–7:00 PM, Tuesday 7:00 AM–6:00 PM, Wednesday 8:00 AM–6:00 PM, Thursday 7:00 AM–6:00 PM	The New Mother's Room is a room set aside for nursing mothers who require a short-term private room. Use of this room is on a first-come, first-served basis.

HOTEL INFORMATION

CROI 2015 hotels are listed below. For more detailed housing information, please visit the CROI 2015 conference website: www.CROI2015.org/housing. Conference attendees are required to stay in one of the official conference hotels. The few exceptions to this include registrants who live in the Seattle area (ie, within a 50-mile radius of the Washington State Convention Center) and registrants who are sharing a room with an approved CROI attendee with accommodations booked via the CROI housing system.

Abstract Content

Author names, institutions, abstract titles, and abstracts in the Program and Abstracts eBook are generally presented as submitted by the corresponding author.

Abstract Review Process

The PC and a panel of external reviewers reviewed the more than 1900 submitted abstracts. Each abstract was scored by 5 to 10 reviewers selected for each abstract category based upon their individual expertise.

PC members and external experts in the field reviewed the abstracts for the quality and originality of the work and scored them numerically. All reviewers were instructed to abstain from scoring any abstract on which they are an author or coauthor, have a financial or personal conflict of interest, or do not have the appropriate expertise to evaluate.

Scores for each abstract were averaged and the standard deviation was calculated to assess variability. If variability was high, outlier scores are identified and censored. Abstracts with high variability in scores were discussed individually during a series of conference calls.

Common Reasons for Abstract Rejection

- Information is not new enough
- Methodology is inadequate or insufficient to support conclusions
- Background does not summarize the hypothesis; submission is poorly written
- Abstract is duplicative of other submissions
- Abstract is not appropriate for CROI
- Controls are absent or inadequate
- Statistical evaluation is inadequate or absent
- Summary of essential results is inadequate or absent
- Data are inadequate or insufficient to support conclusions
- Submission reports clinical trial and data from unplanned analysis or incomplete or ongoing studies
- Format does not follow guidelines (eg, section[s] missing, more than 1 graphic, table, or figure submitted)

EMBARGO POLICY

General

The research presented at CROI 2015 is embargoed until the conclusion of the session in which it is presented. For example, if a study is presented from 2:15 PM to 2:30 PM as part of a session that ends at 3:00 PM, the embargo on that study lifts at 3:00 PM. Embargoes on poster presentations lift at the conclusion of the session in which the poster is presented. If a study to be presented at CROI 2015 is included in an official CROI press conference and that press conference takes place before the official presentation of the study at the conference, the embargo lifts at the conclusion of the press conference in which that study is featured.

Social Media

CROI embargo policies apply to any public dissemination of research information presented at the conference, including through electronic publication (eg, blogs) or social media (eg, Facebook, Twitter). No public dissemination of research information from the conference is permitted prior to the lifting of the conference embargo.

Individuals or organizations that violate the conference embargo policy may have their conference credentials revoked and may forfeit the opportunity to participate in future conferences.

ORAL SESSIONS

MONDAY, FEBRUARY 23, 2015

Session W1 Workshop — Room 6E

9:00 am – 12:30 pm

Program Committee Workshop for New Investigators and Trainees

Target audience: This workshop is directed toward new trainees (eg, undergraduate students, graduate students, postdoctoral fellows, and physician fellows) and new investigators (both international and domestic).

Level of knowledge: It is assumed that participants have been conducting active research in the field for less than 3 years.

Objectives: At the completion of the session, participants will be able to:

- Describe the major areas of HIV investigation being presented at the conference.
- Identify the top 3 to 5 research questions in the field of retroviruses and opportunistic infections today.
- Describe some of the proposed solutions for addressing the challenges presented globally by a variety of retroviruses and opportunistic infections.

Workshop Conveners

Scott M. Hammer, *Columbia University Medical Center/New York-Presbyterian Hospital, New York, NY, US*

John W. Mellors, *University of Pittsburgh, Pittsburgh, PA, US*

1 A Path to an HIV Vaccine
Galit Alter
Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, US

2 Animal Models of HIV Prevention and Cure
Guido Silvestri
Emory University, Decatur, GA, US

3 HIV Prevention 2.0: What's Next?
Susan P. Buchbinder
San Francisco Department of Public Health, San Francisco, CA, US

4 Pathogenesis of HIV Complications
Peter W. Hunt
University of California San Francisco, San Francisco, CA, US

5 HIV Cure Research
John M. Coffin
Tufts University, Boston, MA, US

Session MD Presentation — Room 6E

1:00 pm – 2:00 pm

Martin Delaney Presentation: How to End the HIV Epidemic: Community Perspectives

6 Martin Delaney Presentation: How to End the HIV Epidemic: Community Perspectives

Moderator

Steven F. Wakefield, *HIV Vaccine Trials Network, Fred Hutchinson Cancer Research Center, Seattle, WA, US*

Panelists

Connie Celum, *University of Washington, Seattle, WA, US*

Damon L. Jacobs, *Private Practice Psychotherapist, Brooklyn, NY, US*

Matthew V. Sharp, *Shanti Project, Berkeley, CA, US*

Session W2 Workshop — Room 6E

2:30 pm – 4:30 pm

Clinical Trial Design and Analysis

Target audience: This session is directed to clinicians and scientists who are interested in designing or interpreting clinical trial results.

Level of knowledge: It is assumed that participants are familiar with the basic design of randomized and observational clinical studies.

Objectives: At the completion of the session, participants will be able to:

- Describe strategies for evaluating the effectiveness of interventions.
- Interpret adherence measures.
- Evaluate study design with infrequent endpoints.

Workshop Conveners

Susan P. Buchbinder, *San Francisco Department of Public Health, San Francisco, CA, US*

Richard E. Chaisson, *The Johns Hopkins University, Baltimore, MD, US*

7 Getting SMART About Innovative Designs for Studying Effectiveness: The Case of Adaptive Implementation Interventions
Daniel Almirall
University of Michigan, Ann Arbor, MI, US

8 The Clinical Pharmacology of Medication Adherence
Terrence Blaschke
Stanford University, Stanford, CA, US

9 Epidemiological and Biostatistical Issues in Studying Rare Events in HIV
Stephen J. Gange
Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US

Session W3 Workshop — Room 6D

2:30 pm – 4:30 pm

Frontiers in Laboratory Science

Target audience: This session is directed to investigators and clinicians interested in learning about the main technological and conceptual developments in life sciences that are influencing HIV research or hold a significant potential for research.

Level of knowledge: It is assumed that participants are familiar with the main technological and data analysis approaches used in HIV research.

Objectives: At the completion of the session, participants will be able to:

- Recognize the potential of and directions in the field of big data analysis.
- Describe developments in immunophenotyping and in single-cell analyses.
- Use the basic concepts of integration site analysis to understand current directions in HIV latency research.

Workshop Conveners

Galit Alter, *Ragon Institute of Massachusetts General Hospital, Massachusetts Institute of Technology, and Harvard University, Cambridge, MA, US*

Amalio Telenti, *The J. Craig Venter Institute, La Jolla, CA, US*

10 **Measuring Immunity 1 Cell at a Time**
Mario Roederer
Vaccine Research Center, NIAID, NIH, Bethesda, MD, US

11 **Studying Heterogeneity With Single Cell RNA-Sequencing**
Simon Quenneville
Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland

12 **Integration-Site Analysis**
Frederic D. Bushman
University of Pennsylvania School of Medicine, Philadelphia, PA, US

13 **Discovery and Modeling of Genomic Regulatory Networks With Big Data**
Hamid Bolouri
Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US

Session W4 Workshop — Room 613

2:30 pm – 4:30 pm

Hepatitis C Care in the Interferon-Free Era

Target audience: This session is directed to persons interested in the management of hepatitis C virus (HCV) infection.

Level of knowledge: It is assumed that participants are familiar with the general principles of HCV treatment and the medications used.

Objectives: At the completion of the session, participants will be able to:

- Compare the various methods to stage liver disease.
- Describe the differences and similarities in treatment of HIV/HCV-coinfected persons.
- Recognize how treatment differs for persons with cirrhosis.

Workshop Conveners

Jürgen K. Rockstroh, *University of Bonn, Bonn, Germany*

David L. Thomas, *The Johns Hopkins University, Baltimore, MD, US*

14 **Acute HCV: Is It Still Important to Diagnose and Treat?**
Arthur Y. Kim
[1]Harvard Medical School, Boston, MA, US; [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US

15 **Chronic Genotype 1 Infection**
Debika Bhattacharya
University of California Los Angeles CARE Center, Los Angeles, CA, US

16 **HCV Genotype 3: Our Next Challenge**
Arthur Y. Kim
Massachusetts General Hospital, Boston, MA, US

17 **HCV Cirrhotics With Early Decompensation**
Marion G. Peters
University of California San Francisco, San Francisco, CA, US

Opening Session — 4AB Auditorium

5:00 pm – 7:00 pm

Welcome: Opening Session

Opening Session Hosts

Scott M. Hammer, *Columbia University Medical Center/ New York-Presbyterian Hospital, New York, NY, US*

Julie M. Overbaugh, *Fred Hutchinson Cancer Research Center, Seattle, WA, US*

Susan P. Buchbinder, *San Francisco Department of Public Health, San Francisco, CA, US*

Session NL1 Lecture — 4AB Auditorium

Bernard Fields Lecture

18 **Hepatitis C: Light at the End of the Tunnel**
Charles M. Rice
The Rockefeller University, New York, NY, US

Session NL2 Lecture — 4AB Auditorium

N'Galy-Mann Lecture

19 **Antiretroviral Therapy: Past, Present, and Future**
David A. Cooper
Kirby Institute, University of New South Wales, Sydney, Australia

TUESDAY, FEBRUARY 24, 2015

Session PL-1 Plenary — 4AB Auditorium

8:30 am – 9:00 am

PrEP for HIV Prevention: What We Know and What We Still Need to Know for Implementation

20 **PrEP for HIV Prevention: What We Know and What We Still Need to Know for Implementation**

Raphael J. Landovitz

University of California Los Angeles, Los Angeles, CA, US

Session PL-2 Plenary — 4AB Auditorium

9:00 am – 9:30 am

Specific HIV Integration Sites Linked to Clonal Expansion and Persistence of Cells

21 **Specific HIV Integration Sites Linked to Clonal Expansion and Persistence of Cells**

Stephen H. Hughes

National Cancer Institute, Frederick, MD, US

Session O-1 Oral Abstracts — Room 6AB

10:00 am – 12:15 pm

Preventing HIV and HSV-2: What Will It Take?

Moderators

Sharon L. Hillier, *Magee-Womens Hospital of UPMC, University of Pittsburgh, Pittsburgh, PA, US*

Jorge Sanchez, *Impacta Peru CTU, Barranco, Peru*

22LB **Pragmatic Open-Label Randomised Trial of Preexposure Prophylaxis: The PROUD Study**

Sheena McCormack; David Dunn
On behalf of the PROUD Study Group

MRC Clinical Trials Unit at University College London, London, United Kingdom

23LB **On Demand PrEP With Oral TDF-FTC in MSM: Results of the ANRS Ipergay Trial**

Jean-Michel Molina[1]; Catherine Capitant[2]; Bruno Spire[3]; Gilles Pialoux[4]; Christian Chidiac[5]; Isabelle Charreau[2]; Cecile Tremblay[7]; Laurence Meyer[2]; Jean-Francois Delfraissy[6]
On behalf of the ANRS Ipergay Study Group

[1]University of Paris Diderot, Paris, France; [2]Inserm SC10 US019, Villejuif, France; [3]Inserm U912, Marseille, France; [4]Hopital Tenon, APHP, Paris, France; [5]Hopital de la Croix Rousse, Lyon, France; [6]ANRS, Paris, France; [7]CHUM, Montreal, Canada

24 **Near Elimination of HIV Transmission in a Demonstration Project of PrEP and ART**

Jared Baeten[1]; Renee Heffron[1]; Lara Kidoguchi[1]; Nelly Mugo[2]; Elly Katabira[3]; Elizabeth Bukusi[2]; Stephen Asiimwe[4]; Jessica Haberer[5]; Deborah Donnell[6]; Connie Celum[1]

[1]University of Washington, Seattle, WA, US; [2]Kenya Medical Research Institute, Nairobi, Kenya; [3]Makerere University College of Health Sciences, Kampala, Uganda; [4]Kabwohe Clinical Research Centre, Kabwohe, Uganda; [5]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [6]Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US

25 **Scale-Up of Preexposure Prophylaxis in San Francisco to Impact HIV Incidence**

Robert M. Grant[3]; Albert Liu[2]; Jen Hecht[4]; Susan P. Buchbinder[2]; Shannon Weber[1]; Pierre-Cedric Crouch[4]; Steven Gibson[4]; Stephanie Cohen[2]; David Glidden[1]

[1]University of California San Francisco (UCSF), San Francisco, CA, US; [2]San Francisco Department of Public Health, San Francisco, CA, US; [3]Gladstone Institutes, San Francisco, CA, US; [4]San Francisco AIDS Foundation, San Francisco, CA, US

26LB **FACTS 001 Phase III Trial of Pericoital Tenofovir 1% Gel for HIV Prevention in Women**

Helen Rees[1]; Sinead A. Delany-Moretlwe[1]; Carl Lombard[2]; Deborah Baron[1]; Ravindre Panchia[4]; Landon Myer[3]; Jill L. Schwartz[5]; Gustavo F. Doncel[5]; Glenda Gray[2]
On behalf of the FACTS 001 Study Team

[1]Wits Reproductive Health and HIV Institute, Johannesburg, South Africa; [2]South African Medical Research Council, Cape Town, South Africa; [3]University of Cape Town, Cape Town, South Africa; [4]Perinatal HIV Research Unit, Soweto, South Africa; [5]CONRAD, Arlington, VA, US

27 **Effect of Oral and Gel Tenofovir on Genital HSV Shedding in Immunocompetent Women**

Rachel A. Bender Ignacio[1]; Tara Perti[2]; Amalia S. Magaret[1]; Sharanya Rajagopal[1]; Meei-Lee W. Huang[1]; Christine M. Johnston[1]; Stacy Selke[1]; Jeanne M. Marrazzo[1]; Anna Wald[1]

[1]University of Washington, Seattle, WA, US; [2]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US

28 **Injectable Hormonal Contraception Use and Women's Risk for HSV-2 Acquisition**

Mary K. Grabowski[1]; Ronald H. Gray[1]; Fred Makumbi[2]; Joseph Kagaayi[2]; Andrew D. Redd[3]; Fred Nalugoda[2]; Maria J. Wawer[1]; David Serwadda[4]; Thomas C. Quinn[3]; Aaron A. Tobian[5]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [2]Rakai Health Sciences Program, Kalisizo, Uganda; [3]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD, US; [4]Makerere University College of Health Sciences, Kampala, Uganda; [5]Johns Hopkins University, Baltimore, MD, US

29 **Effect of Financial Incentives on Linkage to Care and Viral Suppression: HPTN 065**

Wafaa M. El-Sadr[1]; Bernard M. Branson[2]; Gheetha Beauchamp[3]; H. Irene Hall[2]; Lucia V. Torian[4]; Barry S. Zingman[5]; Garret Lum[6]; Rick Elion[7]; Theresa Gamble[8]; Deborah Donnell[3]

[1]ICAP at Columbia University, New York, NY, US; [2]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US; [3]SCHARP, Fred Hutchinson Cancer Research Center, Seattle, WA, US; [4]New York City Department of Health and Mental Hygiene, New York, NY, US; [5]Montefiore Medical Center, University Hospital for Albert Einstein College of Medicine, New York, NY, US; [6]District of Columbia Department of Health, Washington, DC, US; [7]Whitman-Walker Health, Washington, DC, US; [8]FHI360, Durham, NC, US

30 **Medical Male Circumcision of HIV-Infected Men Reduces Long-Term Penile HIV Shedding**

Jordyn L. Manucci[1]; Godfrey Kigozi[3]; Mary K. Grabowski[2]; David Serwadda[3]; Ronald H. Gray[2]; Maria J. Wawer[2]; Fred Nalugoda[3]; Andrew D. Redd[4]; Thomas C. Quinn[4]; Aaron A. Tobian[1]

[1]Johns Hopkins University School of Medicine, Baltimore, MD, US; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [3]Makerere University College of Health Sciences, Kampala, Uganda; [4]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, DC, US

Session O-2 Oral Abstracts — Room 613

10:00 am – 12:00 pm

Prevention, Diagnosis, and Treatment of Pediatric HIV Infection

Moderators

Carey Farquhar, *University of Washington, Seattle, WA, US*

Annette H. Sohn, *TREAT Asia/amfAR – The Foundation for AIDS Research, Bangkok, Thailand*

31LB **PROMISE: Efficacy and Safety of 2 Strategies to Prevent Perinatal HIV Transmission**

Mary Glenn Fowler[1]; Min Qin[2]; Susan A. Fiscus[3]; Judith S. Currier[4]; Bonus Makanani[5]; Francis Martinson[6]; Tsungai Chipato[7]; Renee Browning[8]; David Shapiro[2]; Lynne Mofenson[9]
On Behalf of the IMPAACT PROMISE Team

[1]Johns Hopkins University School of Medicine/Makerere University, Baltimore, MD, US; [2]Harvard School of Public Health, Boston, MA, US; [3]University of North Carolina at Chapel Hill, Chapel Hill, NC, US; [4]University of California Los Angeles, Los Angeles, CA, US; [5]Univ of Malawi, Blantyre, Malawi; [6]University of North Carolina Project–Malawi, Lilongwe, Malawi; [7]Univ of Zimbabwe, Harare, Zimbabwe; [8]NIAID/NIH, Bethesda, MD, US; [9]National Institute of Child Health and Human Development, Bethesda, MD, US

32 Most Breastfeeding Women With High Viral Load Are Still Undiagnosed in Sub-Saharan Africa

David Maman[1]; Helena Huerga[1]; Irene Mukui[4]; Benson Chilima[2]; Beatrice Kirubi[5]; Gilles Van Cutsem[6]; Charles Masiku[7]; Elisabeth Szumilin[8]; Thomas Ellman[3]; Jean-François Etard[1]

[1]Epicentre/Médecins Sans Frontières, Paris, France; [2]3. Ministry of Health, Lilongwe, Malawi; [3]Medecins Sans Frontières, Cape Town, South Africa; [4]National AIDS and STDs Control Program, Nairobi, Kenya; [5]Médecins Sans Frontières, Nairobi, Kenya; [6]Médecins Sans Frontières, Cape Town, South Africa; [7]Médecins Sans Frontières, Lilongwe, Malawi; [8]Médecins Sans Frontières, Paris, France

33 Delayed HIV Detection in Infants Exposed to ARV Prophylaxis During Breastfeeding

Caroline C. King[1]; Julie A. Nelson[2]; Carrie Ziemniak[3]; Michael G. Hudgens[2]; Gerald Tegha[4]; Charles S. Chasela[5]; Denise J. Jamieson[1]; Deborah Persaud[3]; Charles M. van der Horst[2]; Athena P. Kourtis[1]

[1]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US; [2]University of North Carolina at Chapel Hill, Chapel Hill, NC, US; [3]Johns Hopkins University, Baltimore, MD, US; [4]UNC Project, Lilongwe, Malawi; [5]University of Witwatersrand, Johannesburg, South Africa

34 Evaluation of the Alere q for Point-of-Care Early Infant HIV Diagnosis in South Africa

Nei-Yuan Hsiao[1]; Max Kroon[2]; Lorna Dunning[2]; Landon Myer[2]

[1]University of Cape Town, Cape Town, South Africa; [2]University of Cape Town, Cape Town, South Africa

35 Early ART and Sustained Virological Suppression Limits HIV Proviral DNA Reservoir: CHER Evidence

Helen A. Payne[1]; Sarah Watters[1]; Marvin Hsaio[2]; Robin Callard[1]; Abdel Babiker[3]; Mark F. Cotton[4]; Kennedy Otwombe[5]; Avy Violari[5]; Diana M. Gibb[3]; Nigel J. Klein[1]

[1]University College London, London, United Kingdom; [2]University of Cape Town, Cape Town, South Africa; [3]MRC Clinical Trials Unit at University College London, London, United Kingdom; [4]Stellenbosch University, Cape Town, South Africa; [5]University of Witswatersrand, Johannesburg, South Africa

36 Long-Term Outcomes of HIV-Infected Children Initiating NVP vs LPV/r-Based Treatment

Linda Barlow-Mosha[1]; Konstantia Angelidou[2]; Moherndran Archary[8]; Avy Violari[7]; Jane Lindsey[2]; Lynne Mofenson[3]; Patrick Jean-Philipe[5]; Paul E Palumbo[4]; Benjamin Chi[6]
On behalf of the IMPAACT P1060 Protocol Team

[1]Makerere University–Johns Hopkins University Research Collaboration, Kampala, Uganda; [2]Harvard School of Public Health, Center for Biostatistics in AIDS Research, Boston, MA, US; [3]National Institutes of Health, Bethesda, MD, US; [4]Geisel School of Medicine at Dartmouth, Lebanon, NH, US; [5]Henry M. Jackson Foundation for the Advancement of Military Medicine, Rockville, MD, US; [6]University of North Carolina at Chapel Hill, Chapel Hill, NC, US; [7]University of Witswatersrand, Johannesburg, South Africa; [8]University of KwaZulu-Natal, Durban, South Africa; [9]IMPAACT, SilverSpring, MD, US

37 Structural Cardiovascular Changes Are Reversible in HIV-Infected Children in Zambia and Uganda.

Julia M. Kenny[1]; Adrian Cook[1]; Grace Mirembe[2]; Dorica Masaku[3]; Priscilla Wavamunno[2]; Florence Odongo[2]; Alicja Rapala[1]; John Deanfield[1]; Diana M. Gibb[1]; Nigel J. Klein[1]

[1]University College London, London, United Kingdom; [2]Joint Clinical Research Centre, Kampala, Uganda; [3]University Teaching Hospital, Lusaka, Zambia

38LB ART With Weekends Off Is Noninferior to Continuous ART in Young People on EFV+2NRTI

Karina M. Butler
On behalf of the BREATHER Trial Team

Our Lady's Children's Hospital, Dublin, Ireland

Session O-3 Oral Abstracts — Room 615

10:00 am – 12:00 pm

Cellular Dynamics, Sensing, and Viral Restriction

Moderators

Jaisri Lingappa, *University of Washington, Seattle, WA, US*

Aine McKnight, *Queen Mary University of London, London, United Kingdom*

39 Envelope Trimer Numbers Required for Entry Steer HIV-1 Infectivity and Entry Kinetics

Oliver Brandenberg[2]; Carsten Magnus[2]; Peter Rusert[2]; Roland Regoes[1]; **Alexandra Trkola**[2]

[1]ETH Zurich, Zurich, Switzerland; [2]University of Zurich, Zurich, Switzerland

40 HIV-1 Accessory Protein Function: Evaluating VPU-Dependent Host Factor Degradation

Prashant Jain; Kevin Olivieri; Quy Nguyen; Paul De Jesus; Sumit Chanda

Sanford-Burnham Medical Research Institute, La Jolla, CA, US

41 HIV-1 Adaptation to Humans Involved Interactions of Vpr With the DNA Damage Response

Oliver I. Fregoso; Michael Emerman

Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US

42 The HIV-1 Protease Can Interact With RNA to Dramatically Enhance Its Activity

Marc Potempa[1]; Ellen Nalivaika[2]; Sook-Kyung Lee[1]; Celia A. Schiffer[2]; Ronald Swanstrom[1]

[1]University of North Carolina, Chapel Hill, NC, US; [2]University of Massachusetts Medical School, Worcester, MA, US

43 PQBP1 Is a Retrovirus-Specific Sensor Mediating cGAS/IRF3-Dependent Innate Responses

Sunnie M. Yoh[1]; Monika Schneider[1]; Stephen Soonthornvarcharin[1]; Rana Akleh[1]; Kevin Olivieri[1]; Paul De Jesus[1]; Chunhai Ruan[2]; Elisa de Castro[3]; Pedro Ruiz[1]; Adolfo Garcia-Sastre[3]

[1]Sanford-Burnham Medical Research Institute, La Jolla, CA, US; [2]University of Michigan, Ann Arbor, MI, US; [3]Icahn School of Medicine at Mount Sinai, New York, NY, US

44 Mucosal HIV-1 Transmission Specifically Selects for Type 1 Interferon-Resistant Viruses

Jackson Foundation for the Advancement of Military Medicine Inc, Silver Spring, MD, US; [2]Fred Hutchinson Cancer Research Center, Seattle, WA, US; [3]University of Washington, Seattle, WA, US; [4]Vaccine Research Center, Bethesda, MD, US; [5]Columbia University, New York, NY, US; [6]US Military HIV Research Program, Silver Spring, MD, US

Session TD-B Themed Discussion — Room 615

1:30 pm – 2:30 pm

Next Generation of Next-Generation Sequencing

Themed Discussion Leader

Davey M. Smith, *University of California San Diego, San Diego, CA, US*

258 PCR-Free Full Genome Characterization of Diverse HIV-1 Strains by Nextgen Sequencing

Viswanath Ragupathy[1]; Feng Gao[2]; Ana Sanchez[2]; Marco Schito[3]; Thomas Denny[2]; Michael Busch[4]; Jiangqin Zhao[1]; Christelle Mbondji[1]; SaiVikram Vemula[1]; Indira Hewlett[1]

[1]US Food and Drug Administration, Silver Spring, MD, US; [2]Duke Human Vaccine Institute and Departments of Medicine, Duke University Medical Center, Durham, NC, US; [3]Henry Jackson Foundation, DAIDS, NIAID, Bethesda, MD, US; [4]Blood Systems Research Institute/University of California San Francisco, San Francisco, CA, US

257 Pan-HIV Next-Gen Sequencing Strategy for Viral Surveillance

Michael G. Berg[1]; Julie Yamaguchi[1]; Elodie Alessandri-Gradt[2]; Jean-Christophe Plantier[2]; Catherine Brennan[1]

[1]Abbott Laboratories, Abbott Park, IL, US; [2]Virology Unit, National Reference for HIV, Rouen, France

256 Near Full Length HIV-1 Sequencing to Understand HIV Phylodynamics in Africa in Real Time

Siva Danaviah; Justen Manasa; Eduan Wilkinson; Sureshnee Pillay; Zandile Sibisi; Sthembiso Msweli; Deenan Pillay; **Tulio de Oliveira**

University of KwaZulu-Natal, Durban, South Africa

254 Present Applications of a High-Throughput, Single Measure HIV Genomic Incidence Assay

Sung Yong Park[1]; Tanzy Love[2]; Nolan Goeken[1]; Robert Bolan[3]; Alan S Perelson[4]; Michael Dube[1]; **Ha Youn Lee**[1]

[1]Keck School of Medicine at University of Southern California, Los Angeles, CA, US; [2]University of Rochester School of Medicine and Dentistry, Rochester, CA, US; [3]Los Angeles Gay and Lesbian Center, Los Angeles, CA, US; [4]Los Alamos National Laboratory, Los Alamos, CA, US

255 A Comprehensive Analysis of Primer IDs to Study Heterogenous HIV-1 Populations

David Seifert[1]; Armin Töpfer[1]; Francesca Di Giallonardo[2]; Stefan Schmutz[2]; Huldrych F. Günthard[2]; Volker Roth[3]; Niko Beerenwinkel[1]; Karin J. Metzner[2]

[1]ETH Zurich, Basel, Switzerland; [2]University Hospital Zurich, Zurich, Switzerland; [3]University of Basel, Basel, Switzerland

593 Analysis of Resistance Haplotypes Using Primer IDs and Next Gen Sequencing of HIV RNA

Valerie F. Boltz[1]; Jason Rausch[1]; Wei Shao[2]; Charles Coomer[1]; John W. Mellors[3]; Mary Kearney[1]; John M. Coffin[4]

[1]National Institutes of Health (NIH), Frederick, MD, US; [2]Leidos, Frederick, MD, US; [3]University of Pittsburgh, Pittsburgh, PA, US; [4]Tufts University, Boston, MA, US

Session TD-C Themed Discussion — Room 613

1:30 pm – 2:30 pm

HIV/CMV Interactions in Transmission and Pathogenesis

Themed Discussion Leader

Victor Appay, *Institut National de la Santé et de la Recherche Médicale, Paris, France*

300 Effect of CMV and HIV Replication on T-Cell Exhaustion and Senescence During ART

Jennifer M. Dan[1]; Marta Massanella[1]; David M. Smith[1]; Eric S. Daar[2]; Michael P. Dube[3]; Richard Haubrich[1]; Sheldon Morris[1]; Sara Gianella Weibel[1]

[1]University of California San Diego, La Jolla, CA, US; [2]Harbor–University of California Los Angeles Medical Center, Torrance, CA, US; [3]University of Southern California Keck School of Medicine, Los Angeles, CA, US

301 HIV Myeloid Derived Suppressor Cells Control Cytomegalovirus Inflammation by IL-27

Ankita Garg; Stephen Spector

University of California San Diego, La Jolla, CA, US

302 Persistent Elevation of Inflammation Markers in HIV+ Persons With CMV Disease

Melissa Schechter[1]; Bruno Andrade[2]; Eleanor M. Wilson[1]; Virginia Sheikh[2]; Sonya Krishnan[2]; Margaret Caplan[1]; Gregg Roby[2]; Adam Rupert[3]; Peter Burbelo[4]; Irini Sereti[2]

[1]NIAID, Leidos Biomedical Inc., Fredrick, MD, US; [2]National Institute of Allergy and Infectious Diseases, Bethesda, MD, US; [3]NIAID, Leidos Biomedical Inc., Fredrick, MD, US; [4]National Institute of Dental and Craniofacial Research, Bethesda, MD, US

303 sCD163 Increase in HIV/CMV-Coinfected Subjects Included in ICONA Cohort

Serena Vita[3]; Miriam Lichtner[1]; Giulia Marchetti[2]; Claudia Mascia[3]; Esther Merlini[2]; Paola Cicconi[2]; Vincenzo Vullo[3]; Pier Luigi Viale[5]; Alberto Costantini[4]; Antonella d'Arminio Monforte[2]
On behalf of the Icona Foundation Study

[1]University of Rome La Sapienza, Polo Pontino, Latina, Italy; [2]San Paolo Hospital, Milano, Italy; [3]University of Rome La Sapienza, Rome, Italy; [4]University of Ancona, Ancona, Italy; [5]University of Bologna, Bologna, Italy

304 Genital CMV Shedding Predicts Syphilis Acquisition in HIV-Infected MSM on ART

Sara Gianella Weibel[1]; David M. Smith[1]; Eric Daar[2]; Michael Dube[3]; Andrea Lisco[4]; Christophe Vanpouille[5]; Richard Haubrich[1]; Sheldon Morris[1]

[1]University of California San Diego, La Jolla, CA, US; [2]Los Angeles Biomedical Research Institute at Harbor–UCLA Medical Center, Torrance, CA, US; [3]University of Southern California Keck School of Medicine, Los Angeles, CA, US; [4]National Institute of Allergy and Infectious Diseases, Bethesda, MD, US; [5]National Institute of Child Health and Human Development, Bethesda, MD, US

Session TD-F Themed Discussion — Room 6D

1:30 pm – 2:30 pm

Leaky Latency

Themed Discussion Leader

Monique Nijhuis, *University Medical Center Utrecht, Utrecht, Netherlands*

392 Defective HIV-1 Proviruses Can Be Transcribed Upon Activation

Ya-Chi Ho; Ross Pollack; Patrick Yong; Robert F. Siliciano

Johns Hopkins University School of Medicine, Baltimore, MD, US

391 Influenza Vaccination Increases HIV-1 Transcription During Antiretroviral Therapy

Christina C. Yek[1]; Sara Gianella[1]; Montserrat Plana[2]; Pedro Castro[2]; Felipe Garcia[2]; Marta Massanella[1]; David M. Smith[1]

[1]University of California San Diego, San Diego, CA, US; [2]University of Barcelona, Barcelona, Spain

427 Measurements of Viral Transcription in Elite Suppressor CD4+ T Cells

Christopher W. Pohlmeyer; C. Korin Bullen; Greg Laird; Alyssa R. Martin; Victoria Walker-Sperling; Stanley U. Chioma; Robert F. Siliciano; Joel Blankson

Johns Hopkins University School of Medicine, Baltimore, MD, US

384 Minor Contribution of Host-HIV Readthrough Transcripts to the Level of HIV-1 *gag* RNA

Alexander Pasternak[1]; Una O'Doherty[2]; Ben Berkhout[1]

[1]Academic Medical Center University of Amsterdam, Amsterdam, Netherlands; [2]University of Pennsylvania, Philadelphia, PA, US

379 Characterizing the Active HIV Reservoir on ART: Cell-Associated HIV RNA and Viremia

Feiyu Hong; Elizabeth Fyne; Anthony R. Cillo; Margaret A. Bedison; Dianna Koontz; John W. Mellors

University of Pittsburgh, Pittsburgh, PA, US

390 Nascent LTR-Driven Transcription Can Lead to Translation of HIV Proteins in Resting CD4+ T Cells

Laura DeMaster[1]; Alexander Pasternak[2]; Una O'Doherty[1]

[1]University of Pennsylvania, Philadelphia, PA, US; [2]Academic Medical Center University of Amsterdam, Amsterdam, Netherlands

Session TD-Q Themed Discussion — Room 6AB

1:30 pm – 2:30 pm

Fat Without Borders: Metabolic Complications in Resource-Limited Settings

Themed Discussion Leader

Miriam Rabkin, *Columbia University Mailman School of Public Health, Chapel Hill, NC, US*

778 Obesity and Inflammation in Resource-Diverse Settings of ART Initiation

Kristine M. Erlandson[1]; Nikhil Gupte[2]; Javier R. Lama[3]; Patcharaphan Sugandhavesa[4]; Thando Mwelase[5]; Ashwin Balagopal[2]; David Asmuth[6]; Thomas B. Campbell[1]; Amita Gupta[2]
On behalf of the A5175 and NWCS319 study team

[1]University of Colorado, Aurora, CO, US; [2]Johns Hopkins University, Baltimore, MD, US; [3]Impacta Peru Clinical Trials Unit, Lima, Peru; [4]Chiang Mai University, Chiang Mai, Thailand; [5]University of Witswatersrand, Johannesburg, South Africa; [6]University of California Davis, Sacramento, CA, US

779 Body Composition Outcomes at 96 Weeks in the SECOND-LINE RCT DXA Substudy

Mark A. Boyd[1]; Janaki Amin[1]; Patrick W. Mallon[2]; Jennifer F. Hoy[3]; Samuel Ferret[4]; Waldo Belloso[5]; Praphan Phanuphak[6]; Sean Emery[1]; David A. Cooper[1]
On behalf of the SECOND-LINE study group

[1]University of New South Wales Australia, Sydney, Australia; [2]University College Dublin, Dublin, Ireland; [3]Monash University/Alfred Hospital, Melbourne, Australia; [4]Hopital Saint Louis, Paris, France; [5]Hospital Italiano, Buenos Aires, Argentina; [6]Thai Red Cross AIDS Research Centre, Bangkok, Thailand

780 Bone Quality by Quantitative Ultrasound at the Radius Does Not Differ in ART-Naïve HIV+ and HIV- Rwandan Women

Eugene Mutimura[1]; Qiuhu Shi[2]; Donald R. Hoover[3]; Kathryn Anastos[4]; Emmanuel Rudakemwa[5]; Jean Claude Dusingize[1]; Jean D'Amour Sinayobye[1]; Michael T Yin[6]

[1]Regional Alliance for Sustainable Development, Kigali, Rwanda; [2]School of Health Sciences and Practice, New York Medical College, New York, NY, US; [3]State University of New Jersey, New Brunswick, NJ, US; [4]Albert Einstein College of Medicine and Montefiore Medical Center, Bronx, NY, US; [5]King Faisal Hospital, Kigali, Rwanda; [6]Columbia University Medical Center, New York, NY, US

781 Predictors and Outcomes of Incident High Cholesterol in Adults on ART in South Africa

Denise Evans[1]; Alana T. Brennan[2]; Faith Moyo[1]; David Spencer[3]; Kay Mahomed[3]; Mhairi Maskew[1]; Lawrence Long[1]; Sydney Rosen[2]; **Matt P. Fox**[2]

[1]University of the Witwatersrand, Johannesburg, South Africa; [2]Boston University, Boston, MA, US; [3]Right to Care, Johannesburg, South Africa

782 Metabolic Changes and Second-Line ART in Africa (2LADY/ANRS 12169 Trial)

Amandine Cournil[1]; Assane Diouf[3]; Sabrina Eymard-Duvernay[1]; Adrien Sawadogo[2]; Liliane Ayangma[4]; Louise Fortes-Deguenonvo[3]; Jean-Marc Mben[6]; Eric Delaporte[1]; Laura Ciaffi[1]; Sinata Koulla-Shiro[5]

[1]IRD/UM 1, Montpellier, France; [2]CHU Souro Sanou, Bobo Dioulasso, Burkina Faso; [3]CRCF, Dakar, Senegal; [4]Yaounde Military Hospital, Yaounde, Cameroon; [5]FMSB/University Yaounde 1, Yaounde, Cameroon; [6]ANRS Research Center, Yaounde, Cameroon

Session TD-S Themed Discussion — Room 6C

1:30 pm – 2:30 pm

Hormonal Contraceptives: Enduring Controversy

Themed Discussion Leader

Betsy Herold, *Albert Einstein College of Medicine, Bronx, NY, US*

859 Estrogen Replacement in Healthy Postmenopausal Women Reduces %CCR5+ CD4+ T Cells

Amie Meditz[1]; Samantha MaWhinney[2]; Kerrie Moreau[2]; Kelsey Melander[2]; Joy Folkvord[2]; Wendy Kohrt[2]; Margaret Wierman[2]; Elizabeth Connick[2]

[1]Boulder Community Health, Boulder, CO, US; [2]University of Colorado Anschutz Medical Campus, Aurora, CO, US

858 CCR5 Expression in HIV-Uninfected Women Receiving Hormonal Contraception

Athe Tsibris[1]; Gaia Sciaranghella[2]; Cuiwei Wang[3]; Kerry Murphy[4]; Zaher Mehri[5]; Ruth M. Greenblatt[6]; Mardge Cohen[7]; Elizabeth Golub[8]; Heather Watts[9]; Mary A. Young[3]

63 Declining Prevalence of HIV-Associated Neurocognitive Disorders in More Recent Years

Carmela Pinnetti; Raffaella Libertone; Pietro Balestra; Patrizia Lorenzini; Martina Ricottini; Samanta Menichetti; Maria Maddalena Plazzi; Mauro Zaccarelli; Adriana Ammassari; Andrea Antinori

National Institute for Infectious Diseases, Lazzaro Spallanzani, Rome, Italy

Session S-1 Symposium — Room 6C

4:00 pm – 6:00 pm

Harnessing Antibodies for Prevention and Therapeutics

Target audience: This session is directed to scientists and clinicians interested in the potential therapeutic and prophylactic applications of anti-HIV antibodies.

Level of knowledge: It is assumed that participants are familiar with basic immunologic principles, antibody structure, and HIV envelope variability.

Objectives: At the completion of the session, participants will be able to:

- List cutting-edge approaches for the delivery of protective and curative antibodies.
- Describe emerging approaches to enhance monoclonal antibody activity against virus.
- Describe new advances in the ability to elicit antibodies that resemble neutralizing antibodies through vaccination.

Symposium Conveners

Leonidas Stamatatos, *Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US*

Susan Zolla-Pazner, *New York University, Langone Medical Center*

64 Potentiating Protective Antibody Activity: A Systems Serology Approach

Margaret E. Ackerman

Thayer School of Engineering, Dartmouth College, Hanover, NH, US

65 Impact of Repetitive Protein Boosting on RV305 HIV-1 Vaccine-Induced Antibodies

Georgia D. Tomaras

Duke University Medical Center, Durham, NC, US

66 Immunoprophylaxis by Gene Transfer: Shortcut to an HIV Vaccine

Phil Johnson

Children's Hospital of Philadelphia, Philiadlphia, PA, US

67 Broadly Neutralizing Antibodies for HIV-1 Eradication Strategies

Dan H. Barouch

Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, US

Session S-2 Symposium — Room 6D

4:00 pm – 6:00 pm

Current Issues in HIV-Related Malignancies

Target audience: This session is directed to those interested in development and management of cancers in HIV.

Level of knowledge: It is assumed that participants have some basic knowledge of types of cancers seen in HIV.

Objectives: At the completion of the session, participants will be able to:

- Discuss differences in malignancy incidence and presentation, including in resource-limited settings around the world.
- Describe new concepts in viral-induced oncogenesis.
- Describe new therapies for lymphoma in HIV-infected individuals.
- Examine major barriers for treatment of cancers in resource-limited settings.

Symposium Conveners

Margaret Z. Borok, *University of Zimbabwe, College of Health Sciences, Harare, Zimbabwe*

Robert Yarchoan, *National Cancer Institute, Bethesda, MD, US*

68 HIV-Associated Malignancies: The Worldwide Epidemic

James J. Goedert

National Cancer Institute, Bethesda, MD, US

69 Viral Oncogenesis: Evolving Concepts

Shannon C. Kenney

University of Wisconsin, Madison, WI, US

70 AIDS Lymphoma: Advances and Existing Challenges

Ariela Noy

Memorial Sloan Kettering Cancer Center, New York, NY, US

71 HIV Malignancies in Low- and Middle-Income Countries: A Double Burden of Disease

Jackson Orem

Uganda Cancer Institute, Kampala, Uganda

Session S-3 Symposium — Room 6AB

4:00 pm – 6:00 pm

Current Imperatives in HIV Prevention and Treatment

Target audience: This session is directed to researchers, public health professionals, and educators interested in global HIV and public health.

Level of knowledge: It is assumed that participants are familiar with HIV program scale-up and global disease burden.

Objectives: At the completion of the session, participants will be able to:

- Define trends in HIV/AIDS and sexually transmitted infection epidemiology among different groups.
- Describe the epidemiology of HIV among men who have sex with men in Africa, and associated challenges.
- Assess broader impact on health programs and behavioral science of HIV/AIDS service scale-up.

Symposium Conveners

Wafaa M. El-Sadr, *ICAP at Columbia University, New York, NY, US*

Lucy Ng'ang'a, *CDC Center for Global Health, Division of Global AIDS/HIV, Nairobi, Kenya*

72 How Has HIV Prevention Affected the Spread of Other Sexually Transmitted Infections?

Marie Laga

Institute of Tropical Medicine, Antwerp, Belgium

73 HIV Risks and Vulnerabilities Among Gay Men and Other Men Who Have Sex With Men Across Sub-Saharan Africa

Stefan Baral

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US

74 An Expanded Behavioral Paradigm for Treatment and Prevention of HIV-1

Thomas J. Coates

University of California Los Angeles, Los Angeles, CA, US

75 Social Protection, Financial Incentives, and Prevention of HIV

David Wilson

World Bank, Washington, DC, US

Special Session **Room 6E**

6:30 pm – 7:30 pm

Special Session: Ebola Virus Disease: Responding to the Challenge

Moderators

Kevin M. De Cock, *Centers for Disease Control and Prevention, Nairobi, Kenya*

Wafaa M. El-Sadr, *ICAP at Columbia University, New York, NY, US*

76 **The Médecins Sans Frontières Experience With the Current Ebola Outbreaks**

Gilles Van Cutsem

Médecins Sans Frontières, Mowbray, Cape Town, South Africa

77 **Ebola Treatment and Vaccine Development and Implementation: Challenges and Opportunities**

H. Clifford Lane

National Institute of Allergy and Infectious Diseases, Bethesda, MD, US

WEDNESDAY, FEBRUARY 25, 2015

Session PL-1 Plenary — 4AB Auditorium

8:30 am – 9:00 am

Preventing Pediatric HIV and Managing HIV-Infected Children: Where Are We Now and Where Are We Going?

78 **Preventing Pediatric HIV and Managing HIV-Infected Children: Where Are We Now, and Where Are We Going?**

Diana M. Gibb

University College London, London, United Kingdom

Session PL-2 Plenary — 4AB Auditorium

9:00 am – 9:30 am

Directing Chronic Virus Infection Through Viral Regulation of Innate Immune Defenses

79 **Directing Chronic Virus Infection Through Viral Regulation of Innate Immune Defenses**

Michael Gale

University of Washington, Center for Innate Immunity and Immune Disease, Seattle, WA, US

Session O-6 Scientific Overview and Oral Abstracts — Room 615

10:00 am – 12:00 pm

Intracellular and Clinical Pharmacology, Drug Interactions, and Adherence

Moderators

Reina Bendayan, *University of Toronto, Toronto, ON, Canada*

Marta Boffito, *Chelsea and Westminster Hospital, NHS Foundation Trust/Imperial College, London, United Kingdom*

80 **Scientific Overview: The Clinical Pharmacology of HIV Prevention**

Marta Boffito

Chelsea and Westminster Hospital, NHS Foundation Trust/Imperial College, London, United Kingdom

81 **Intracellular Pharmacokinetics of Sofosbuvir In Vivo**

Joseph Rower[1]; Ariel Hodara[1]; Jacob A. Langness[3]; Sarah Tise[1]; Greg Everson[1]; Aimee Truesdale[2]; Fafa Baouchi-Mokrane[2]; Lane Bushman[1]; Peter L. Anderson[1]; Jennifer J. Kiser[1]

[1]University of Colorado Denver, Anschutz Medical Campus, Aurora, CO, US; [2]Denver Health and Hospital Authority, Denver, CO, US; [3]University of Colorado Health, Aurora, CO, US; [4]University of Colorado Denver, Anschutz Medical Campus, Aurora, CO, US

82 **Drug-Drug Interactions Between Anti-HCV Regimen Ledipasvir/Sofosbuvir and Antiretrovirals**

Polina German; Kimberly Garrison; Phillip S. Pang; Luisa M. Stamm; Adrian S. Ray; Gong Shen; Marc Buacharern; Anita Mathias

Gilead Sciences, Inc., Foster City, CA, US

83 **Emtricitabine-Triphosphate in Dried Blood Spots (DBS) as a Marker of Recent Dosing**

Jose R. Castillo-Mancilla[1]; Lane R. Bushman[1]; Amie Meditz[2]; Sharon M. Seifert[1]; Jia-Hua Zheng[1]; L Anthony Guida[1]; Edward M. Gardner[3]; David V. Glidden[4]; Robert M. Grant[4]; Peter L. Anderson[1]

[1]University of Colorado-AMC, Aurora, CO, US; [2]Beacon Center for Infectious Diseases, Boulder, CO, US; [3]Denver Health and Hospital Authority, Denver, CO, US; [4]University of California San Francisco, San Francisco, CA, US

84 **Impact of EFV PK/PG on Neuropsychological Performance in Older HIV+ Patients**

Uriel S. Sandkovsky[1]; Anthony T. Podany[1]; Courtney Fletcher[1]; Andrew Owen[2]; Angela Felton-Coleman[1]; Kevin Robertson[3]; Susan Swindells[1]

[1]University of Nebraska Medical Center, Omaha, NE, US; [2]University of Liverpool, Liverpool, United Kingdom; [3]University of North Carolina, Chapel Hill, NC, US

85LB **Levonorgestrel Implant + EFV-Based ART: Unintended Pregnancies and Associated PK Data**

Kimberly K. Scarsi[1]; Kristin M. Darin[3]; Shadia Nakalema[2]; David Back[4]; Pauline Byakika-Kibwika[2]; Laura Else[4]; Sujan Dilly-Penchala[4]; Susan Cohn[3]; Concepta Merry[5]; Mohammed Lamorde[2]

[1]University of Nebraska Medical Center, Omaha, NE, US; [2]Infectious Diseases Institute, Kampala, Uganda; [3]Northwestern University, Feinberg School of Medicine, Chicago, IL, US; [4]University of Liverpool, Liverpool, United Kingdom; [5]Trinity College Dublin, Dublin, Ireland

86LB **A Phase IV PrEP Study Reveals Limited Ex Vivo Potency of Oral Maraviroc Against HIV-1**

Julie Fox[1]; Carolina Herrera[2]; Juan Manuel Tiraboschi[1]; Akil Jackson[3]; Laura Else[4]; Natalia Olejniczak[2]; Saye Khoo[4]; David Back[4]; Robin Shattock[2]; Marta Boffito[3]
On behalf of KCL Infectious Diseases Biobank

[1]Guys and St Thomas' NHS Foundation Trust, London, United Kingdom; [2]Imperial College London, London, United Kingdom; [3]Chelsea and Westminster Hospital, NHS Foundation Trust, London, United Kingdom; [4]University of Liverpool, Liverpool, United Kingdom

Session O-7 Oral Abstracts — Room 613

10:00 am – 12:15 pm

KS and Cervical/Anal Dysplasia: Tale of 2 Tumors, and TB and Other OIs

Moderators

Corey Casper, *Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US*

Timothy Sterling, *Vanderbilt University, Nashville, TN, US*

87 **Pomalidomide for Kaposi Sarcoma in People With and Without HIV: A Phase I/II Study**

Mark N. Polizzotto[1]; Thomas S. Uldrick[1]; Kathleen M. Wyvill[1]; Karen Aleman[1]; Margaret Bevans[2]; Cody Peer[1]; Douglas Figg[1]; Seth Steinberg[1]; Jerome B. Zeldis[5]; Robert Yarchoan[1]

[1]National Cancer Institute (NCI), Bethesda, MD, US; [2]National Institutes of Health (NIH), Bethesda, MD, US; [3]National Cancer Institute (NCI), Bethesda, MD, US; [4]National Cancer Institute (NCI), Bethesda, MD, US; [5]Celgene Corporation, Summit, NJ, US

88 **Prognostic Model for Patients With Kaposi Sarcoma Treated With ART Alone in Africa**

Miriam O. Laker-Oketta[1]; David V. Glidden[2]; Victoria Walusansa[1]; Jackson Orem[1]; A. Rain Mocello[2]; Toby Maurer[2]; Peter W. Hunt[2]; Andrew D. Kambugu[1]; Edward Mbidde[1]; **Jeffrey Martin**[2]

[1]Makerere University College of Health Sciences, Kampala, Uganda; [2]University of California San Francisco, San Francisco, CA, US; [3]Makerere University College of Health Sciences, Kampala, Uganda; [4]University of California San Francisco (UCSF), San Francisco, CA, US; [5]University of California San Francisco (UCSF), San Francisco, CA, US

89 **One-Year Follow-up of HIV+ Women Screened With VIA, Cytology and HPV in South Africa**

Cynthia Firnhaber[1]; Bridgette Goeieman[1]; Lu Mao[2]; Mark Faesen[3]; Simon Levin[3]; Sophie Williams[3]; Avril Swarts[1]; Pam Michelow[1]; Tanvier Omar[1]; Jennifer Smith[2]

[1]University of Witswatersrand, Johannesburg, South Africa; [2]University of North Carolina, Raleigh, NC, US; [3]Right to Care, Johannesburg, South Africa

90 **High Rate of HSIL on HRA in HIV+ Women Not Meeting Criteria for Anal Cancer Screening**

Michael M. Gaisa; **Fanny Ita-Nagy**; Gabriela Rodriguez Caprio; Michael Mullen; Judith Aberg; Michelle Cespedes

Icahn School of Medicine at Mount Sinai, New York, NY, US

91 **Xpert MTB/RIF Ultra: A New Near-Patient TB Test With Sensitivity Equal to Culture**

David Alland[1]; Mazhgan Rowneki[1]; Laura Smith[1]; Jamie Ryan[2]; Mitchell Chancellor[2]; Ann Marie Simmons[2]; David Persing[2]; Robert Kwiatkowski[2]; Martin Jones[2]; Soumitesh Chakravorty[1]

[1]Rutgers New Jersey Medical School, Newark, NJ, US; [2]Cepheid, Sunnyvale, CA, US

92 Majority of XDR TB Cases Are Due to Transmission in a High-HIV-Prevalence Setting

N. Sarita Shah[1]; James C. Brust[2]; Barun Mathema[3]; Thuli Mthiyane[4]; Nazir Ismail[5]; Pravi Moodley[6]; Koleka Mlisana[8]; Salim Allana[7]; Jonathan Smith[7]; Neel R. Gandhi[7]

[1]US Centers for Disease Control and Prevention, Atlanta, GA, US; [2]Montefiore Medical Center & Albert Einstein College of Medicine, Bronx, NY, US; [3]Columbia University Mailman School of Public Health, New York, NY, US; [4]University of KwaZulu-Natal, Durban, South Africa; [5]National Institute for Communicable Diseases, National Health Laboratory Service, Johannesburg, South Africa; [6]University of KwaZulu-Natal & National Health Laboratory System, Durban, South Africa; [7]Emory University Rollins School of Public Health, Atlanta, GA, US; [8]University of KwaZulu-Natal & National Health Laboratory Service, Durban, South Africa

93 Linkage to HIV/TB Care in South Africa: A Randomized Trial of Health Navigators

Ingrid V. Bassett[2]; Sharon M. Coleman[1]; Janet Giddy[4]; Laura M. Bogart[3]; Christine E. Chaisson[1]; Douglas Ross[5]; Tessa Govender[4]; Kenneth A. Freedberg[2]; Rochelle P. Walensky[2]; Elena Losina[2]

[1]Boston University School of Public Health, Boston, MA, US; [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [3]Boston Children's Hospital, Harvard Medical School, Boston, MA, US; [4]McCord Hospital, Durban, South Africa; [5]St. Mary's Hospital, Mariannhill, South Africa

94 Is It Safe to Stop Cotrimoxazole in Adults on ART: COSTOP, a Noninferiority RCT

Paula Munderi[1]; **Jonathan B. Levin**[1]; Zacchaeus Anywaine[1]; Ronnie Kasirye[1]; Anatoli Kamali[1]; Andrew J. Nunn[2]; Heiner Grosskurth[3]
On behalf of COSTOP Research Team

[1]MRC/UVRI Uganda Research Unit on AIDS, Entebbe, Uganda; [2]University College London, London, United Kingdom; [3]London School of Hygiene and Tropical Medicine, London, United Kingdom

95LB High-Dose Rifampin, SQ109 and Moxifloxacin for Treating TB: The PanACEA MAMS-TB Trial

Martin J. Boeree[1]; Michael Hoelscher[2]
On behalf of the PanACEA consortium

[1]Radboudumc, Nijmegen, Netherlands; [2]University of Munich, Munich, Germany

Session O-8 Special Presentation and Oral Abstracts — Room 6E

10:00 am – 12:15 pm

Factors Affecting HIV Care and Outcome: Global Perspective

Moderators

Ruanne V. Barnabas, *University of Washington, Seattle, WA, US*

Elizabeth Bukusi, *University of California San Francisco, San Francisco, CA, US*

96 Special Presentation: PEPFAR 3.0: Controlling the Epidemic and Delivering on the Promise of an AIDS-Free Generation

Ambassador Deborah L. Birx, MD
US Department of State, Washington, DC, US

97 Joint Estimation of HIV Progression and Survival: A Pooled Analysis of 25 Countries

Tara D. Mangal
On behalf of the UNAIDS Working Group on CD4 Progression and Mortality Among HIV Seroconverters including the CASCADE Collaboration in EuroCoord
Imperial College London, London, United Kingdom

98 Impact of Emergency Department HIV Testing and Linkage to Care: 25 Years' Experience

Gabor Kelen[3]; Eshan U. Patel[2]; Yu-Hsiang Hsieh[3]; Oliver B. Laeyendecker[2]; Judy Shahan[3]; William Clarke[3]; Jordyn L. Manucci[3]; Richard Rothman[3]; **Thomas C. Quinn**[2]

[1]Johns Hopkins University School of Medicine, Baltimore, MD, US; [2]National Institute of Allergy and Infectious Diseases (NIAID), Baltimore, MD, US; [3]Johns Hopkins University School of Medicine, Baltimore, MD, US

99 Linkage to Care and Viral Suppression Among New HIV Diagnoses, New York City, 2006-13

Ellen W. Wiewel; **Lucia V. Torian**; Qiang Xia; Sarah L. Braunstein
New York City Department of Health and Mental Hygiene, Long Island City, NY, US

100 Care and Viral Suppression Among Women, 18 US Jurisdictions

Ndidi Ike; Angela L. Hernandez; Qian An; Taoying Huang; H. Irene Hall
US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US

101 Time Above 1500 Copies/ml: A Viral-Load Measure for Assessing Transmission Risk of HIV-Positive Patients in Care

Lytt I. Gardner[1]; Gary Marks[1]; Charles Rose[1]; Meg Sullivan[2]; Susan Holman[3]; Jeanne Keruly[4]; Anne Zinski[5]; Allan Rodriguez[6]; Thomas Giordano[7]

[1]Centers for Disease Control and Prevention, Atlanta, GA, US; [2]Boston University School of Medicine, Boston, MA, US; [3]Colleges of Medicine and Nursing, SUNY Downstate Medical Center, Brooklyn, NY, US; [4]Johns Hopkins University School of Medicine, Baltimore, MD, US; [5]University of Alabama at Birmingham, Birmingham, AL, US; [6]Miller School of Medicine, University of Miami, Miami, FL, US; [7]Baylor College of Medicine, Houston, TX, US

102 Incidence and Risk Factors for Sexual Assault Among MSM and Young Women in Coastal Kenya

Adrian D. Smith[1]; Sam Rogers[1]; Elizabeth Wahome[2]; Marianne Darwinkel[2]; Susan M. Graham[3]; Eduard J. Sanders[2]

[1]Nuffield Department of Population Health, Oxford, United Kingdom; [2]Centre for Geographic Medicine Research – Coast, Kilifi, Kenya; [3]University of Washington, Seattle, WA, US

103LB Impact of the Ebola Epidemic on HIV Care in Macenta, Forest Guinea, 2014

David Leuenberger[1]; Jean Hébélamou[1]; Stefan Strahm[1]; Gilles Wandeler[2]; Nathalie de Rekeneire[3]; François Dabis[3]
On behalf of International Epidemiological Databases to Evaluate AIDS - West Africa

[1]Mission Philafricaine, Conakry, Guinea; [2]Department of Infectious Diseases, University Hospital Bern, Bern, Switzerland; [3]Université Bordeaux, ISPED, Centre Inserm U897-Epidemiologie-Biostatistique, Bordeaux, France

103-ALB Favipiravir in Patients with Ebola Virus Disease: Early Results of the JIKI trial in Guinea

Daouda Sissoko[1], Elin Folkesson[2], M'lebing Abdoul[3], Abdoul Habib Beavogui[4], Stephan Gunther[6], Susan Shepherd[3], Christine Danel[1],France Mentre[5], Xavier Anglaret[1], **Denis Malvy**[1]

[1]Inserm U897, Université de Bordeaux, Bordeaux, France; [2]Médecins Sans Frontières, Bruxelles, Belgium; [3]ALIMA, Montreuil, France; [4]Centre de Formation et de Recherche en Santé Rurale de Maférinyah, Conakry, Guinée; [5]Inserm U738, Université Paris Diderot, Paris, France; [6]Bernhard-Nocht-Institut für Tropenmedizin, Hamburg, Germany

Session O-9 Oral Abstracts — Room 6D

10:00 am – 12:15 pm

New Insights Into HIV Persistence, Latency Reversal, and Viremia Rebound

Moderators

Francoise Barre-Sinoussi, *Institut Pasteur*

Celsa A. Spina, *University of California San Diego, La Jolla, CA, US*

104LB Durable Control of Viral Rebound in Humanized Mice by ABX464 Targeting Rev Functions

Noelie Campos[1]; Renier Myburgh[3]; Aude Garcel[1]; Audrey Vautrin[2]; Laure Lapasset[2]; Katjana Tantale[2]; Mark Wainberg[4]; Roberto Speck[3]; Didier Scherrer[1]; **Jamal Tazi**[2]

[1]ABIVAX, Montpellier, France; [2]University of Montpellier, Montpellier, France; [3]University of Zurich, Zurich, Switzerland; [4]McGill AIDS Center, Montréal, Canada

105 Residual Viremia Caused by Clonally Expanded Tumor-Infiltrating CD4+ Cells

Francesco R. Simonetti[1]; Michele D. Sobolowski[2]; Shawn Hill[1]; Wei Shao[3]; Elizabeth Fyne[2]; Xiaolin Wu[1]; John M. Coffin[4]; Stephen H. Hughes[1]; John W. Mellors[2]; Frank Maldarelli[1]

[1]National Cancer Institute (NCI), Frederick, MD, US; [2]University of Pittsburgh, Pittsburg, PA, US; [3]Frederick National Laboratory for Cancer Research, Frederick, MD, US; [4]Tufts University, Boston, MA, US; [5]National Cancer Institute (NCI), Frederick, MD, US

106 Analysis of HIV RNA in Single Cells Reveals Clonal Expansions and Defective Genomes

Ann Wiegand[1]; Jonathan Spindler[1]; Wei Shao[2]; Feiyu Hong[3]; Anthony R. Cillo[3]; Elias Halvas[3]; Elizabeth Fyne[3]; John M. Coffin[4]; John W. Mellors[3]; **Mary F. Kearney**[1]

[1]National Cancer Institute, Frederick, MD, MD, US; [2]Leidos, Frederick, MD, US; [3]University of Pittsburgh, Pittsburgh, PA, US; [4]Tufts University, Boston, MA, US

107 Low-Level HIV Viremias Originate in Part From Infected Proliferating Cells

Marta E. Bull[1]; Sherry McLaughlin[2]; Hannah Huang[2]; Sheila Styrchak[2]; Jaime Soria[3]; Eduardo Ticona[3]; Alberto La Rosa[4]; Caroline Mitchell[5]; James Mullins[1]; Lisa Frenkel[1]

[1]University of Washington, Seattle, WA, US; [2]Seattle Children's Research Institute, Seattle, WA, US; [3]Hospital Nacional dos de Mayo, Lima, Peru; [4]Investigaciones Médicas en Salud (INMENSA), Lima, Peru; [5]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, US; [6]University of Washington, Seattle, WA, US

108 Treatment With a TLR7 Agonist Induces Transient Viremia in SIV-Infected ART-Suppressed Monkeys

James B. Whitney[1]; So-Yon Lim[1]; Christa E. Osuna[1]; Srisowmya Sanisetty[1]; Tiffany L. Barnes[2]; Peter T. Hraber[3]; Tomas Cihlar[2]; Romas Geleziunas[2]; Joseph Hesselgesser[2]

[1]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, US; [2]Gilead Sciences, Inc., Foster City, CA, US; [3]Los Alamos National Laboratories, Los Alamos, NM, US

109 Panobinostat Broadly Activates Latent HIV-1 Proviruses in Patients

Kirston M. Barton[1]; Thomas A. Rasmussen[2]; Martin Tolstrup[2]; Wei Shao[4]; Bonnie Hiener[1]; Ajantha Solomon[3]; Lars Østergaard[2]; Sharon R. Lewin[3]; Ole Søgaard[2]; **Sarah E. Palmer**[1]

[1]Westmead Millennium Institute and University of Sydney, Westmead, Australia; [2]Aarhus University Hospital, Aarhus, Denmark; [3]Doherty Institute for Infection and Immunity, Melbourne, Australia; [4]National Cancer Institute, Rockville, MD, US

110LB The Size of the Active HIV Reservoir Predicts Timing of Viral Rebound

Behzad Etemad[1]; Hayat Ahmed[1]; Evgenia Aga[2]; Ronald Bosch[2]; John W. Mellors[3]; Daniel Kuritzkes[1]; Michael Para[4]; Rajesh T. Gandhi[5]; **Jonathan Li**[1]

[1]Brigham and Women's Hospital, Harvard Medical School, Cambridge, MA, US; [2]Harvard School of Public Health, Center for Biostatistics in AIDS Research, Boston, MA, US; [3]University of Pittsburgh, Pittsburgh, PA, US; [4]Ohio State University, Columbus, OH, US; [5]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US

111LB Biomarkers to Predict Viral Rebound at Antiretroviral Therapy Interruption in SPARTAC

Jacob Hurst[1]; James Williams[1]; John P. Thornhill[2]; Matthew Pace[1]; Chris Willberg[1]; Elizabeth Hamlyn[3]; Abdel Babiker[4]; Rodney Phillips[1]; Sarah Fidler[2]; **John Frater**[1]
on behalf of the SPARTAC Trial Investigators

[1]University of Oxford, Oxford, United Kingdom; [2]St Mary's Hospital–Imperial College Healthcare NHS Trust, London, United Kingdom; [3]King's College London, London, United Kingdom; [4]Medical Research Council Clinical Trials Unit, London, United Kingdom

112LB HIV-1 Diversity and Tropism of Rebound Virus After Treatment Discontinuation

Maria M. Bednar[1]; Blake Hauser[1]; Jeffrey M. Jacobson[2]; Ian Frank[4]; Joseph J. Eron[3]; Ronald Swanstrom[1]
On behalf of the NWCS 379 team

[1]University of North Carolina, Durham, NC, US; [2]Drexel University College of Medicine, Philadelphia, PA, US; [3]University of North Carolina, Chapel Hill, NC, US; [4]University of Pennsylvania, Philadelphia, PA, US

Session TD-A Themed Discussion — Room 615

1:30 pm – 2:30 pm

Interferon: Triggers and Effectors

Themed Discussion Leader

Martin R. Jakobsen, *Aarhus University,Aarhus C, Denmark*

188 HIV-1 Exploits CD169 to Evade IFNα-Induced Antiviral State in Myeloid Cells

Hisashi Akiyama[1]; Nora Ramirez[1]; Gregory Gibson[2]; Simon Watkins[2]; Zandrea Ambrose[2]; Rahm Gummuluru[1]

[1]Boston University School of Medicine, Boston, MA, US; [2]University of Pittsburgh School of Medicine, Pittsburgh, PA, US; [3]University of Pittsburgh School of Medicine, Pittsburgh, PA, US

192 HIV and SIV Inhibition by RNA-Associated Early Stage Antiviral Factor (REAF)

Aine McKnight

Queen Mary University of London, London, United Kingdom

184 Regulation of the Innate Immune Sensing of HIV by the Viral Capsid and the Cytosolic DNA Sensor cGAS

Nicolas Manel

Institut Curie, Paris, France

203 Mapping Vpx and Vpr Specificity in Antagonism of SAMHD1

Chelsea Spragg; Michael Emerman

Fred Hutchinson Cancer Research Center, Seattle, WA, US

202 A Surprising New Function of SAMHD1 as a Pro-Pathogenic Factor in HIV Infection

Gilad Doitsh; Nicole Galloway; Xin Geng; Isa Monus Arias; Zhiyuan Yang; Warner C. Greene

The J. David Gladstone Institute, University of California San Francisco, San Francisco, CA, US

191 Characterization of the Activity of an Innate Immunity Protein, the Apolipoprotein L6

Nitisha Pyndiah[1]; Angela Ciuffi[1]; Amalio Telenti[2]

[1]Institute of Microbiology, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland; [2]J Craig Venter Institute, San Diego, CA, US

Session TD-H Themed Discussion — Room 613

1:30 pm – 2:30 pm

New Technologies in Assessing Drug Interactions and Systemic and Intracellular Pharmacology

Themed Discussion Leader

Tim R. Cressey, *Harvard School of Public Health / Chiang Mai University, Chiang Mai, Thailand*

531 Pharmacokinetic Interactions Between Antidiabetics and Efavirenz Using PBPK Modeling

Catia Marzolini[1]; Rajith Rajoli[2]; Luigia Elzi[1]; Manuel Battegay[1]; David Back[2]; Marco Siccardi[2]

[1]University Hospital Basel, Basel, Switzerland; [2]Institute of Translational Medicine, University of Liverpool, Liverpool, United Kingdom

532 In Silico Simulation of Interaction Between Rifampicin and Boosted Darunavir

Marco Siccardi; Owain Roberts; Rajith Rajoli; Laura Dickinson; Saye Khoo; Andrew Owen; David Back

University of Liverpool, Liverpool, United Kingdom

533 Pharmacogenetics of Pregnancy-Induced Changes in Efavirenz Pharmacokinetics

Adeniyi Olagunju[1]; Oluseye Bolaji[2]; Alieu Amara[1]; Laura Else[1]; Ogechi Okafor[3]; Ebunoluwa Adejuyigbe[2]; Oyigboja Johnson[4]; David Back[1]; Saye Khoo[1]; Andrew Owen[1]

[1]University of Liverpool, Liverpool, United Kingdom; [2]Obafemi Awolowo University, Ile-Ife, Nigeria; [3]Bishop Murray Medical Centre, Makurdi, Nigeria; [4]Catholic Caritas Foundation of Nigeria, Makurdi, Nigeria

534 Antiretroviral Drug Transporters and Metabolic Enzymes in Human Testicular Tissue

Billy Huang[1]; Md. Tozammel Hoque[1]; Mohammad-Ali Jenabian[3]; Kishanda Vyboh[2]; Nancy Sheehan[2]; Pierre Brassard[4]; Maud Bélanger[4]; Nicolas Chomont[5]; Jean-Pierre Routy[2]; Reina Bendayan[1]

[1]University of Toronto, Toronto, Canada; [2]McGill University, Montréal, Canada; [3]Université du Québec à Montréal, Montréal, Canada; [4]Metropolitan Centre of Plastic Surgery, Montréal, Canada; [5]Vaccine and Gene Therapy Institute of Florida, Port St Lucie, FL, US

535 Imaging the Spatial Distribution of Efavirenz in Intact HIV Tissue Reservoirs

Elias P. Rosen[1]; Corbin G. Thompson[2]; Mark T. Bokhart[1]; Craig Sykes[2]; Yuri Fedoriw[2]; Paul Luciw[3]; David C. Muddiman[1]; Angela D.M. Kashuba[2]

[1]North Carolina State University, Raleigh, NC, US; [2]University of North Carolina, Chapel Hill, NC, US; [3]University of California Davis, Davis, CA, US

Session TD-O Themed Discussion — Room 6D

1:30 pm – 2:30 pm

Cancers in Young and Old, and Lung Cancer in HIV

Themed Discussion Leader

Eric A. Engels, *National Cancer Institute (NCI), Bethesda, MD, US*

724 Cancer in HIV-Infected Children: Record Linkage Study in South Africa

Julia Bohlius[6]; Nicky Maxwell[2]; Brian Eley[3]; Hans Prozesky[4]; Shobna Sawry[1]; Karl-Günter Technau[1]; Alan Davidson[2]; Cristina Stefan[5]; **Matthias Egger**[6]
On behalf of IeDEA Southern Africa

[1]University of the Witwatersrand, Johannesburg, South Africa; [2]University of Cape Town, Cape Town, South Africa; [3]Red Cross War Memorial Children's Hospital, Cape Town, South Africa; [4]University of Stellenbosch and Tygerberg Academic Hospital, Cape Town, South Africa; [5]Stellenbosch University and Tygerberg Hospital, Cape Town, South Africa; [6]University of Bern, Bern, Switzerland

725 High Cancer Risk Among the HIV-Infected Elderly in the United States

Elizabeth L. Yanik; Hormuzd A. Katki; Eric A. Engels

National Cancer Institute (NCI), Rockville, MD, US

726 Smoking Outweighs HIV-Related Risk Factors for Non–AIDS-Defining Cancers

Keri N. Althoff[1]; Stephen J. Gange[1]; Chad Achenbach[2]; Lisa P. Jacobson[1]; Angel M. Mayor[3]; Michael J. Silverberg[4]; Amy Justice[5]; Richard Moore[6]; Yuezhou Jing[1]; Kelly Gebo[6]
On behalf of the North American AIDS Cohort Collaboration on Research and Design

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [2]Northwestern University, Feinberg School of Medicine, Chicago, IL, US; [3]Universidad Central del Caribe, Bayamon, US; [4]Kaiser Permanente Northern California, Oakland, CA, US; [5]Veterans Affairs Connecticut Healthcare System and Yale Schools of Medicine and Public Health, New Haven, CT, US; [6]Johns Hopkins University School of Medicine, Baltimore, MD, US

727 High Frequency of Early Lung Cancer Diagnosis With Chest CT in HIV-Infected Smokers

Alain Makinson[1]; Sabrina Eymard-Duvernay[2]; François Raffi[3]; Fabrice Bonnet[4]; Laurence Thirard[5]; Pierre Tattevin[6]; Sophie Abgrall[7]; Jacques Reynes[1]; Vincent Le Moing[1]
on behalf of the ANRS EP48 HIV CHEST Study Team

[1]University Hospital Montpellier, UMI233, Montpellier, France; [2]UMI 233, IRD, University Montpellier 1, Montpellier, France; [3]Nantes University Hospital, Nantes, France; [4]University Hospital Bordeaux, Inserm U897, Bordeaux, France; [5]Tourcoing University Hospital, Tourcoing, France; [6]Pontchaillou University Hospital, Rennes, France; [7]University Hospital Avicennes, Bobigny, France; [8]ANRS, Paris, France

728 CD4 Measures as Predictors of Lung Cancer Risk and Prognosis in HIV Infection

Keith Sigel[1]; Kristina Crothers[2]; Kirsha Gordon[3]; Sheldon Brown[4]; David Rimland[5]; Maria Rodriguez-Barradas[6]; Cynthia Gibert[7]; Matthew B. Goetz[8]; Roger Bedimo[9]; Robert Dubrow[10]

Session TD-R Themed Discussion — Room 6E

1:30 pm – 2:30 pm

Cryptococcal Meningitis: Host Response, Treatment, and Outcomes

Themed Discussion Leader

Judith A. Aberg, *Icahn School of Medicine at Mount Sinai, New York, NY, US*

834 Local and Systemic Humoral Responses to Cryptococcal Meningitis in Patients With AIDS

Erin E. Finn[1]; Jordan Janoff[1]; Jeremy Rahkola[1]; David B. Meya[2]; Samuel Okurut[2]; Andrew D. Kambugu[2]; Paul Bohjanen[3]; Kirsten Nielsen[3]; David R. Boulware[3]; Edward N. Janoff[1]

[1]Mucosal and Vaccine Research Colorado, Aurora, CO, US; [2]Makerere University College of Health Sciences, Kampala, Uganda; [3]University of Minnesota, Minneapolis, MN, US

835 Antiretroviral Therapy Alters the CSF Immune Response in Cryptococcal Meningitis

James E. Scriven[1]; Britta Urban[1]; Lisa Graham[2]; Charlotte Schutz[2]; Robert J. Wilkinson[3]; David R. Boulware[4]; David Lalloo[1]; Graeme Meintjes[2]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom; [2]University of Cape Town, Cape Town, South Africa; [3]Imperial College London, London, United Kingdom; [4]University of Minnesota, Minneapolis, MN, US

836 Detrimental Outcomes of Unmasking Cryptococcal Meningitis With Recent ART Initiation

Joshua Rhein[1]; Katherine H. Hullsiek[1]; Nathan C. Bahr[1]; Reuben Kiggundu[3]; Darlisha Williams[3]; Henry W. Nabeta[3]; Abdu Musubire[3]; David B. Meya[3]; David R. Boulware[1]

[1]University of Minnesota, Minneapolis, MN, US; [2]University of Minnesota, Minneapolis, MN, US; [3]Makerere University College of Health Sciences, Kampala, Uganda

837 Impact of ART on Mortality in Cryptococcal Meningitis Patients: High-Income Settings

Suzanne M. Ingle[1]; Jose M. Miro[2]; Hansjakob Furrer[4]; Amy Justice[5]; Michael S. Saag[6]; Christian Manzardo[2]; Anna Esteve[7]; Lauren E. Cain[3]; Jonathan A. Sterne[1]; Margaret T. May[1]

[1]University of Bristol, Bristol, United Kingdom; [2]Hospital Clínic–L'Institut D'Investigacions Biomèdiques August Pi i Sunyer, University of Barcelona, Barcelona, Spain; [3]Harvard School of Public Health, Boston, MA, US; [4]Bern University Hospital and University of Bern, Bern, Switzerland; [5]Yale University School of Medicine, VA Connecticut Healthcare System, New Haven, CT, US; [6]University of Alabama at Birmingham, Birmingham, AL, US; [7]Centre d'Estudis Epidemiològics Sobre ITS/VIH/SIDA de Catalunya, Barcelona, Spain

838 Adjunctive Sertraline for the Treatment of HIV-Associated Cryptococcal Meningitis

Joshua Rhein[1]; Katherine H. Hullsiek[1]; Bozena Morawski[1]; Kyle Smith[1]; Ali Al-Hadab[1]; Abdu Musubire[2]; Darlisha Williams[2]; Kristen Nielsen[1]; David B. Meya[2]; David R. Boulware[1]

[1]University of Minnesota, Minneapolis, MN, US; [2]Makerere University College of Health Sciences, Kampala, Uganda

Session TD-W Themed Discussion — Room 6AB

1:30 pm – 2:30 pm

Serosorting and Seroadaptive Behavior: What's Your Position?

Themed Discussion Leader

Andrew E. Grulich, *University of New South Wales, Sydney, NSW, Australia*

1060 Trends in Sexual Behaviors Among Men Who Have Sex With Men in the United States, the Role of Antiretroviral Therapy and Seroadaptive Strategies

Gabriela Paz-Bailey[1]; Maria Mendoza[1]; Binh Le[1]; Charles E. Rose[1]; Teresa Finlayson[1]; Cyprian Wejnert[1]; Henry F. Raymond[2]; Joseph Prejean[1]

[1]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US; [2]San Francisco Department of Public Health, San Francisco, CA, US

1061 Changes in Condomless Sex and Serosorting Among MSM After HIV Diagnosis

Christine M. Khosropour[2]; Julia C. Dombrowski[2]; David A. Katz[2]; Matthew R. Golden[2]

[1]University of Washington, Seattle, WA, US; [2]University of Washington, Seattle, WA, US

1062 Serosorting and Sexual Risk Behavior Influenced by Perceived HIV Serostatus Among MSM

Kathleen A. Brady; Jennifer Shinefeld; Catherine Mezzacappa

Philadelphia Department of Public Health, Philadelphia, PA, US

1063 Use of the Seroadaptive Strategies of Sexual Positioning and Serosorting by MSM in Nigeria

Cristina M. Rodriguez-Hart[1]; Hongjie Liu[2]; Ifeanyi K. Orazulike[3]; Sam Zorowitz[4]; Sylvia Adebajo[5]; Lindsay Hughes[6]; Stefan Baral[7]; Merlin L. Robb[6]; William Blattner[1]; Manhattan Charurat[1]

[1]University of Maryland School of Medicine, Baltimore, MD, US; [2]University of Maryland School of Public Health, College Park, MD, US; [3]International Center on Advocacy and Rights to Health, Abuja, Nigeria; [4]Massachusetts General Hospital and Harvard Medical School, Boston, MA, US; [5]Population Council, Abuja, Nigeria; [6]US Military HIV Research Program, Bethesda, MD, US; [7]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US

Session TD-Z Themed Discussion — Room 6C

1:30 pm – 2:30 pm

Economic Implications of ART

Themed Discussion Leader

John Blandford, *US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US*

1104 The Lifetime Medical Cost Savings From Preventing HIV in the United States

Bruce R. Schackman[1]; John Fleishman[6]; Amanda Su[2]; Richard Moore[5]; Rochelle Walensky[2]; David Paltiel[3]; Milton Weinstein[4]; Kenneth Freedberg[2]; Kelly Gebo[5]; Elena Losina[2]

[1]Weill Cornell Medical College, New York, NY, US; [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [3]Yale School of Public Health, New Haven, CT, US; [4]Harvard School of Public Health, Boston, MA, US; [5]Johns Hopkins University School of Medicine, Baltimore, MD, US; [6]Agency for Healthcare Research and Quality, Rockville, MD, US

1119 Survival Benefits Attributable to the Brazilian National ART Policy

Paula M. Luz[1]; Michael P. Girouard[2]; Beatriz Grinsztejn[1]; Kenneth Freedberg[2]; Valdilea Veloso[1]; Elena Losina[4]; Claudio Struchiner[1]; Robert Parker[2]; David Paltiel[3]; Rochelle Walensky[2]

[1]Fundacao Oswaldo Cruz, Rio de Janeiro, Brazil; [2]Massachusetts General Hospital, Boston, MA, US; [3]Yale School of Public Health, New Haven, CT, US; [4]Brigham and Women's Hospital, Boston, MA, US

1110 The Cost-Effectiveness of Early ART Initiation in South Africa: A Quasi-Experiment

Jacob Bor[1]; Ellen Moscoe[2]; Natsayi Chimbindi[3]; Kobus Herbst[3]; Kevindra K. Naidu[3]; Frank Tanser[3]; Deenan Pillay[3]; Till Barnighausen[3]

[1]Boston University School of Public Health, Boston, MA, US; [2]Harvard School of Public Health, Boston, MA, US; [3]Wellcome Trust Africa Centre for Health and Population Studies, Somkhele, South Africa

1111 Community-Based Strategies to Strengthen the Continuum of HIV Care Are Cost-Effective

Jennifer A. Smith[1]; Monisha Sharma[2]; Carol Levin[2]; Jared Baeten[2]; Heidi van Rooyen[3]; Connie Celum[2]; Timothy Hallett[1]; Ruanne V. Barnabas[2]

[1]Imperial College London, London, United Kingdom; [2]University of Washington, Seattle, WA, US; [3]Human Sciences Research Council, Sweetwaters, South Africa

1114 Global Fund Cost Projections for Implementing WHO 2013 Guidelines

Obinna Onyekwena; Ade Fakoya; Michael Johnson; Michael Olszak-Olszewski; Mark Dybul

The Global Fund to Fight AIDS, Tuberculosis and Malaria, Geneva, Switzerland

Session O-10 Oral Abstracts — Room 6C

4:00 pm – 6:15 pm

New Antiretroviral Agents, Strategies, and HIV Drug Resistance

Moderators

Constance Delaugerre, *Hôpital Saint-Louis, APHP, Université Paris Diderot, Paris, France*

Richard Harrigan, *BC Centre for Excellence in HIV/AIDS, Vancouver, BC, Canada*

113LB Tenofovir Alafenamide (TAF) in a Single-Tablet Regimen in Initial HIV-1 Therapy

David Wohl[1]; Anton Pozniak[2]; Melanie Thompson[3]; Edwin DeJesus[4]; Daniel Podzamczer[5]; Jean-Michel Molina[6]; Gordon Crofoot[7]; Christian Callebaut[8]; Hal Martin[8]; Scott McCallister[8]

[1]University of North Carolina, Chapel Hill, NC, US; [2]Chelsea and Westminster Hospital, NHS Foundation Trust, London, United Kingdom; [3]AIDS Research Consortium of Atlanta, Atlanta, GA, US; [4]Orlando Immunology Center, Orlando, FL, US; [5]Hospital Universitari de Bellvitge, Barcelona, Spain; [6]Hopital Saint Louis, Paris, France; [7]Gordon Crofoot Research, Houston, TX, US; [8]Gilead Sciences, Inc, Foster City, CA, US; [9]Gilead Sciences, Inc, Foster City, CA, US

114LB Antiviral Activity/Safety of a Second-Generation HIV-1 Maturation Inhibitor

Carey Hwang[1]; Dirk Schürmann[2]; Christian Sobotha[2]; Heather Sevinsky[1]; Palanikumar Ravindran[1]; Hong Xiao[1]; Neelanjana Ray[1]; Mark Krystal[3]; Ira B. Dicker[3]; **Max Lataillade**[3]

[1]Bristol-Myers Squibb, Princeton, NJ, US; [2]Charité Research Organisation GmbH, Berlin, Germany; [3]Bristol-Myers Squibb, Wallingford, CT, US

115LB Early ART and IPT in HIV-Infected African Adults With High CD4 Count (Temprano Trial)

Christine Danel[1]; Raoul Moh[2]; Delphine Gabillard[1]; Anani Badje[4]; Jerome Le Carrou[1]; Gerard M. Kouame[4]; Jean Baptiste Ntakpe[4]; Hervé Ménan[3]; Serge Eholie[2]; Xavier Anglaret[1]
On behalf of the Temprano Study Group

[1]Inserm, Bordeaux, France; [2]Université Felix Houphouet Boigny, Abidjan, Côte d'Ivoire; [3]CHU de Treichville, Abidjan, Côte d'Ivoire; [4]Programme PACCI, Abidjan, Côte d'Ivoire

116 Antiretroviral Drug Screening Provides Key Insights Into HIV Drug Resistance

Iris Chen[1]; Matthew B. Connor[2]; William Clarke[1]; Mark A. Marzinke[1]; Vanessa Cummings[1]; Sheldon D. Fields[3]; Darrell P. Wheeler[4]; Kenneth H. Mayer[5]; Beryl A. Koblin[6]; Susan H. Eshleman[1]

[1]Johns Hopkins University School of Medicine, Baltimore, MD, US; [2]Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US; [3]Florida International University, Miami, FL, US; [4]Loyola University Chicago, Chicago, IL, US; [5]Fenway Health, Boston, MA, US; [6]New York Blood Center, New York, NY, US

117 Untimed Drug Levels and Resistance in Patients Experiencing Low-Level HIV Viremia

Alejandro Gonzalez-Serna; Luke C. Swenson; Adriana Nohpal; Birgit Watson; Kate Auyeung; Julio Montaner; Richard Harrigan

BC Centre for Excellence in HIV/AIDS, Vancouver, Canada

118 Pretreatment HIV Drug Resistance Increases Regimen Switch in Sub-Saharan Africa

Tamara Sonia Boender[1]; Bernice M. Hoenderboom[1]; Kim C. Sigaloff[1]; Maureen Wellington[2]; Margaret Siwale[3]; Cissy M. Kityo[4]; Alani Sulaimon Akanmu[5]; Mariette E. Botes[6]; Tobias F. Rinke de Wit[1]
On behalf of the PASER Study Group

[1]Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands; [2]Newlands Clinic, Harare, Zimbabwe; [3]Lusaka Trust Hospital, Lusaka, Zambia; [4]Joint Clinical Research Centre, Kampala, Uganda; [5]Lagos University Teaching Hospital, Lagos, Nigeria; [6]Muelmed Hospital, Pretoria, South Africa

119 Impact of NRTI Cross-Resistance on Second-Line PI + NRTI Therapy Outcomes in Africa

Nicholas Paton[1]; Cissy Kityo[2]; Jennifer Thompson[5]; Leonard Bagenda[2]; James Hakim[6]; Joep van Oosterhout[4]; Andrew D. Kambugu[3]; Anne Hoppe[5]; Sarah Walker[5]
On behalf of the EARNEST Trial Team

[1]National University of Singapore, Singapore, Singapore; [2]Joint Clinical Research Centre, Kampala, Uganda; [3]Infectious Diseases Institute, Kampala, Uganda; [4]University of Malawi, Blantyre, Malawi; [5]MRC Clinical Trials Unit at University College London, London, United Kingdom; [6]University of Zimbabwe Clinical Research Centre, Harare, Zimbabwe

120 Fitness Effects of Drug-Resistant Strains Across the United States HIV-1 Transmission Network

Joel O. Wertheim[1]; Alexandra M. Oster[2]; Neeraja Saduvala[2]; Walid Heneine[2]; Jeffery A. Johnson[2]; William M. Switzer[2]; Angela L. Hernandez[2]; H. Irene Hall[2]

[1]University of California San Diego, San Diego, CA, US; [2]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US

121 Dolutegravir Resistance Requires Multiple Primary Mutations in HIV-1 Integrase

Arne Frantzell; Christos J Petropoulos; **Wei Huang**

Monogram Biosciences, South San Francisco, CA, US

Session S-4 Symposium — Room 613

4:00 pm – 6:00 pm

Making Sense of Sensing: Innate Immunity and HIV Infection

Target audience: This session is directed to clinicians and scientists interested in innate immune defenses against HIV, viral countermeasures, and the relevance of the ongoing arms race between both of these for the pathogenesis and spread of AIDS.

Level of knowledge: It is assumed that participants are familiar with the basics of HIV replication.

Objectives: At the completion of the session, participants will be able to:

- Describe the most current understanding of how the human host senses, responds to, and restricts HIV infection, and how the virus evades or counteracts host defense mechanisms.
- Appreciate the role of innate immunity in the pathogenesis and spread of HIV disease.

Symposium Conveners

Nathaniel Landau, *NYU School of Medicine, New York, NY, US*
Jairam R. Lingappa, *University of Washington, Seattle, WA, US*

122 **Role of Tetherin in the Evolution and Spread of HIV-1**
Daniel Sauter
Ulm University Medical Center, Ulm, Germany

123-A **Innate Sensing of HIV-1 in Macrophages**
Martin R. Jakobsen
Aarhus University, Aarhus C, Denmark

124 **Innate Sensing and Signaling to HIV-1 in Dendritic Cells**
Teunis Geijtenbeek
Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands

125 **How HIV-1 Evades DNA Sensors**
Vineet KewalRamani
National Cancer Institute, Frederick, MD, US

Session S-5 Symposium
Room 6D

4:00 pm – 6:00 pm

Advancing HIV Prevention: Lessons from Biology, Medicine, and Public Health Law

Target audience: This session is directed to clinicians, scientists, and policy makers who are interested in developing or implementing HIV prevention programs for maximal benefit.

Level of knowledge: It is assumed that participants are familiar with basic HIV epidemiology and transmission, and the effect of antiretroviral drugs for preexposure prophylaxis and treatment as prevention.

Objectives: At the completion of the session, participants will be able to:

- Determine how new insights into HIV transmission can assist prevention programs.
- Describe the barriers to scale up of test-and-treat approaches and how the law can help (or inhibit) prevention efforts.

Symposium Conveners

Meg C. Doherty, *World Health Organization (WHO), Geneva, Switzerland*
Jeanne M. Marrazzo, *University of Washington, Seattle, WA, US*

126 **The Biology of HIV Transmission: What We Think We Know and How We Know It**
Julie M. Overbaugh
Fred Hutchinson Cancer Research Center, Seattle, WA, US

127 **HIV Phylogenetics: Lessons for HIV Prevention**
Christophe Fraser
Imperial College London, London, United Kingdom

128 **Optimizing ART: Treatment as Prevention in the US: Will It Be Enough?**
Richard A. Elion
Whitman-Walker Health, Washington, DC, US

129 **Criminalizing HIV: Recent Experience in the United States and Africa to Update Laws and Policies to Promote the Public Health**
Jeffrey Crowley
Georgetown University, Washington, DC, US

Session S-6 Symposium — Room 6E

4:00 pm – 6:00 pm

Tuberculosis: Magic Bullets and Moving Targets

Target audience: This session is directed to clinicians and scientists interested in the pathogenesis, clinical manifestations, treatment, and prevention of tuberculosis (TB).

Level of knowledge: It is assumed that participants are familiar with basic TB epidemiology, clinical features, and treatment.

Objectives: At the completion of the session, participants will be able to:

- List new techniques for TB diagnosis.
- Describe new investigational TB treatment options and strategies.
- Describe the unique situation of children and pregnant women infected with TB.

Symposium Conveners

Alison Grant, *London School of Hygiene and Tropical Medicine, London, United Kingdom*
Ilesh V. Jani, *Instituto Nacional de Saúde, Maputo, Mozambique*

130 **Advances in Mycobacterial Diagnostics**
Mark P. Nicol
University of Cape Town, Cape Town, South Africa

131 **New Medications, Innovative Approaches: Accelerate the TB Regimen Development Pipeline**
Michael Hoelscher
University of Munich, Munich, Germany

132 **Tuberculosis in Pregnancy**
Amita Gupta
Johns Hopkins University School of Medicine, Baltimore, MD, US

133 **Tuberculosis in Children**
Anneke C. Hesseling
Stellenbosch University, Cape Town, South Africa

THURSDAY, FEBRUARY 26, 2015

Session PL-1 Plenary — 4AB Auditorium

8:30 am – 9:00 am

Cardiovascular Disease in HIV Patients: An Emerging Paradigm and Call to Action

134 Cardiovascular Disease in HIV Patients: An Emerging Paradigm and Call to Action

Steven Grinspoon

Massachusetts General Hospital, Harvard Medical School, Boston, MA, US

Session PL-2 Plenary — 4AB Auditorium

9:00 am – 9:30 am

The Price of Selling Sex: HIV Among Female Sex Workers—The Context and the Public Health Response

135 The Price of Selling Sex: HIV Among Female Sex Workers—The Context and the Public Health Response

Frances M. Cowan

University College London, London, United Kingdom

Session O-11 Oral Abstracts — Room 6C

10:00 am – 12:15 pm

Cardiovascular, Bone, and Kidney Health

Moderators

Jennifer F. Hoy, *The Alfred Hospital and Monash University, Melbourne, Victoria, Australia*

Edgar T. Overton, *University of Alabama at Birmingham, Birmingham, AL, US*

136 Statin Therapy Reduces Coronary Noncalcified Plaque Volume in HIV Patients: A Randomized Controlled Trial

Janet Lo[1]; Michael Lu[2]; Ezinne Ihenachor[1]; Jeffrey Wei[1]; Sara Looby[1]; Kathleen Fitch[1]; Suhny Abbara[2]; Gregory Robbins[1]; Udo Hoffmann[2]; Steven Grinspoon[1]

[1]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [2]Massachusetts General Hospital, Boston, MA, US

137 Rosuvastatin Arrests Progression of Carotid Intima-Media Thickness in Treated HIV

Chris T. Longenecker[1]; Ying Jiang[1]; Sara M. Debanne[1]; Danielle Labbato[2]; Bruce Kinley[2]; Norma Storer[2]; **Grace A. McComsey**[1]

[1]Case Western Reserve University, Cleveland, OH, US; [2]University Hospitals of Cleveland, Cleveland, OH, US

138 Calcified Plaque Burden Is Associated With Serum Gut Microbiota-Generated TMA in HIV

Suman Srinivasa[1]; Kathleen V. Fitch[1]; Janet Lo[1]; Hanane Kadar[2]; Kimberly Wong[1]; Suhny Abbara[3]; Dominique Gauguier[2]; Jacqueline Capeau[2]; Franck Boccara[2]; Steven K. Grinspoon[1]

[1]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [2]University Pierre & Marie Curie, Paris, France; [3]University of Texas Southwestern Medical Center, Dallas, TX, US

139 Varenicline vs Placebo for Smoking Cessation: ANRS 144 Inter-ACTIV Randomized Trial

Patrick Mercie[3]; Caroline Roussillon[1]; Christine Katlama[4]; Aurélie Beuscart[1]; Samuel Ferret[2]; Nathalie Wirth[5]; David Zucman[6]; Xavier Duval[7]; Genevieve Chene[1]
On behalf of the ANRS 144 inter-ACTIV study group

[1]Inserm U897, Bordeaux, France; [2]Hosp. Saint-Louis, Paris, France; [3]Hosp. Saint-André, Bordeaux, France; [4]Hosp. La Pitié-Salpêtrière, Paris, France; [5]Hosp. De Brabois, Vandoeuvre les Nancy, France; [6]Hosp. Foch, Suresnes, France; [7]CIC 1425, Paris, France

140 Body Composition Changes After Initiation of Raltegravir or Protease Inhibitors

Grace A. McComsey[1]; Carlee Moser[2]; Judith S. Currier[8]; Heather Ribaudo[2]; Pawel Paczuski[2]; Michael P. Dube[5]; Robert L. Murphy[6]; Jennifer Rothenberg[7]; James H. Stein[4]; Todd T. Brown[3]

[1]Case Western Reserve University, Cleveland, OH, US; [2]Harvard School of Public Health, Center for Biostatistics in AIDS Research, Boston, MA, US; [3]Johns Hopkins University School of Medicine, Baltimore, MD, US; [4]University of Wisconsin School of Medicine and Public Health, Madison, WI, US; [5]University of Southern California, Los Angeles, CA, US; [6]Northwestern University, Chicago, IL, US; [7]Social & Scientific Systems, Inc., Silver Spring, MD, US; [8]University of California Los Angeles, Los Angeles, CA, US

141 Fracture Prediction With Modified FRAX in Older HIV+ and HIV- Men

Michael T. Yin[1]; Melissa Skanderson[7]; Stephanie Shiau[1]; Katherine Harwood[1]; Josh Aschheim[3]; David Rimland[2]; Cynthia Gibert[5]; Maria Rodriguez-Barradas[4]; Roger Bedimo[6]; Julie Womack[7]

[1]Columbia University Medical Center, New York, NY, US; [2]VAMC and Emory School of Medicine, Atlanta, GA, US; [3]Arcadia Healthcare Solutions, New York, NY, US; [4]Baylor College of Medicine, Houston, TX, US; [5]VA Medical Center, George Washington University, Washington, DC, US; [6]University of Texas, Dallas, TX, US; [7]VA Connecticut Healthcare System, West Haven, CT, US

142 Exposure to Antiretrovirals (ARVs) and Development of Chronic Kidney Disease (CKD)

Amanda Mocroft[1]; Jens D. Lundgren[2]; Michael Ross[3]; Christoph Fux[4]; Peter Reiss[5]; Olivier Moranne[6]; Philippe Morlat[7]; Antonella d'Arminio Monforte[8]; Ole Kirk[2]; Lene Ryom[2]
On behalf of the Data Collection on Adverse Events of Anti-HIV Drugs (D:A:D) Study Group

[1]University College London, London, United Kingdom; [2]Copenhagen HIV Programme, Centre for Health and Infectious Diseases Network, University of Copenhagen, Denmark, Denmark; [3]Division of Nephrology, Mount Sinai School of Medicine, New York, NY, US; [4]Clinic for Infectious Diseases and Hospital Hygiene, Kantonsspital Aarau, Aarau, Switzerland; [5]Academic Medical Center, Div. of Infectious Diseases and Dept. of Global Health, University of Amsterdam, Amsterdam, Netherlands; [6]Université de Bordeaux, Inserm U 897, Bordeaux, France; [7]Public Health Department, Nice, France; [8]Istituto Di Clinica Malattie Infettive e Tropicale, Milan, Italy

143LB Renal and Bone Safety of Tenofovir Alafenamide vs Tenofovir Disoproxil Fumarate

Paul E. Sax[7]; Michael S. Saag[2]; Michael T. Yin[3]; Frank A. Post[4]; Shinichi Oka[8]; Ellen Koenig[5]; Benoit Trottier[9]; Jaime Andrade-Villanueva[6]; Huyen Cao[1]; Marshall W. Fordyce[1]

[1]Gilead Sciences Inc, Foster City, CA, US; [2]University of Alabama at Birmingham, Birmingham, AL, US; [3]College of Physicians and Surgeons, Columbia University, New York, NY, US; [4]King's College Hospital, London, United Kingdom; [5]Dominican Institute for Virologic Studies, Santo Domingo, Dominican Republic; [6]Unidad de VIH del Hospital Civil de Guadalajara, Guadalajara, Mexico; [7]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, US; [8]National Center for Global Health and Medicine, Japan, Tokyo, Japan; [9]Clinique Medicale l'Actuel, Montreal, Canada

144 Special Presentation: Update on National Heart, Lung, and Blood Institute High-Impact AIDS Research

Monica Shah

National Heart, Lung, and Blood Institute, Bethesda, MD, US

Session O-12 Oral Abstracts — Room 6AB

10:00 am – 12:00 pm

Curing HCV: Mission Accomplished

Moderators

Karine Lacombe, *Saint Antoine Hospital, AP-HP, Paris, France*

John W. Ward, *Centers for Disease Control and Prevention, Atlanta, GA, US*

145 The Burden of Liver Disease Among Persons With Hepatitis C in the United States

Session S-7 Symposium — Room 613

4:00 pm – 6:00 pm

From Pathways to Paradigms: Applications of Systems Biology to HIV/Host Interactions

Target audience: This session is directed to scientists and clinicians who are interested in recent advances in the use of RNA profiling, transcriptomic analyses, microarrays, and other state-of-the-art methodologies in an integrated approach (ie, systems biology) to probe new insights and hypotheses in HIV and SIV pathogenesis, prevention, and treatment.

Level of knowledge: It is assumed that participants are familiar with the basic concepts and challenges in the fields of HIV pathogenesis, prevention, and treatment and have some familiarity with the cellular processes that underlie the molecular biology of viral-host interactions.

Objectives: At the completion of the session, participants will be able to:

- Recognize how integrative approaches to profiling RNA transcription can be applied to provide new interpretations of relevant problems in HIV pathogenesis research.
- Appreciate how a systems-biology approach can generate new hypotheses for developing novel interventions for HIV prevention and therapy.
- Discuss emerging technologies and bioinformatics analyses that have enabled molecular signatures and networks to be identified and applied to relevant questions for HIV and other infectious pathogens.

Symposium Conveners

Steven Bosinger, *Emory University, Yerkes National Primate Research Center*

Raphael Gottardo, *Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US*

171 Using Systems Approaches to Study Pathogenesis: Bridging Networks and Mechanisms

Nevan Krogan

University of California San Francisco, San Francisco, CA, US

172 Molecular Basis of T-Cell Exhaustion

E. John Wherry

University of Pennsylvania, Philadelphia, PA, US

173 A Systems Biology Approach to Identify Targets and Mechanisms of HIV Latency and HIV Eradication

Rafick P. Sekaly

Case Western Reserve University, Cleveland, OH, US

174 Translating Anti–HIV-1 Immune Mechanisms Into Clinical Interventions

Sallie R. Permar

Duke University, Durham, NC, US

Session S-8 Symposium — Room 6D

4:00 pm – 6:00 pm

Scale-Up of Interventions

Target audience: This session is directed to researchers and programmers interested in the scale-up of HIV programs around the world.

Level of knowledge: It is assumed that participants are familiar with HIV prevention methods, the impact of HIV on key populations, HIV testing approaches, laboratory assays in support of HIV prevention, and HIV care and treatment.

Objectives: At the completion of the session, participants will be able to:

- Describe scientific evidence relating to male circumcision and its programmatic scale-up for HIV prevention.
- Describe scientific bases for interventions for people who inject drugs.
- Describe recent evidence and trends concerning scale-up of HIV testing.
- Describe the role of laboratory infrastructure and systems required to support HIV/AIDS program scale-up.

Symposium Conveners

Linda-Gail Bekker, *Desmond Tutu HIV Foundation, South Africa*

Kevin M. De Cock, *Centers for Disease Control and Prevention, Nairobi, Kenya*

175 From Equipoise to Efficacy to Millions Reached With Voluntary Medical Male Circumcision for HIV Prevention

Jason B. Reed

US Department of State, Office of the Global AIDS Coordinator, Washington, DC, US

176 Scale-Up of HIV Interventions for People Who Inject Drugs: Quality and Coverage

Anna Deryabina

ICAP at Columbia University, Almaty, Kazakhstan

177 HIV Testing and Counseling: Emerging Issues, New Directions

Rachel C. Baggaley

World Health Organization, Geneva, Switzerland

178 Ten Years of Strengthening Laboratory Services and Systems: Then, Now, and the Future

John Nkengasong

US Centers for Disease Control and Prevention, Atlanta, GA, US

Session S-9 Symposium — Room 6E

4:00 pm – 6:00 pm

HCV: New Frontiers and Controversies

Target audience: This session is directed to persons who are interested in the basic science, public health impact, and management of hepatitis C virus (HCV) infections.

Level of knowledge: It is assumed that participants are familiar with general concepts of virology and medicine.

Objectives: At the completion of the session, participants will be able to:

- Describe the mechanisms by which HCV affects the liver.
- Recognize the cells that HIV infects within the liver.
- Describe the impact of HCV eradication on HCV transmission, and the pitfalls.

Symposium Conveners

Chloe M. Orkin, *Barts Health NHS Trust, London, United Kingdom*

David L. Wyles, *University of California San Diego (UCSD), La Jolla, CA, US*

179 Pathogenesis of Acute HCV Infection

Ashwin Balagopal

Johns Hopkins University School of Medicine, Baltimore, MD, US

180 HCV Treatment as Prevention: Challenges and Opportunities

Gregory Dore

University of New South Wales, Sydney, Australia

181 HCV Therapeutics: It's the Virus, Stupid

Mark S. Sulkowski

Johns Hopkins University School of Medicine, Baltimore, MD, US

182 HCV Therapeutics: Big Sticks With Big Stickers

Marion G. Peters

University of California San Francisco, San Francisco, CA, US

POSTER SESSIONS, BY CATEGORY

All poster sessions will be held in the Poster Hall from 2:30 PM to 4:00 PM on the scheduled day.

A: Virology
P-A1: Cellular Innate Immunity: Tuesday, 2/24/2015
P-A2: Nucleus Entry, Integration, and Export: Wednesday, 2/25/2015
P-A3: SAMHD1: Tuesday, 2/24/2015
P-A4: Enhancers and Inhibitors of Viral Infectivity and Entry: Thursday, 2/26/2015
P-A5: Envelopes, Receptors, and Tropism: Wednesday, 2/25/2015
P-A6: Nef Functions: Thursday, 2/26/2015

B: Molecular Epidemiology and HIV/SIV Evolution
P-B1: Viral Origins and Recombinant Forms: Thursday, 2/26/2015
P-B2: Defining Epidemiologically Linked Transmission: Tuesday, 2/24/2015
P-B3: Transmission Clusters: Wednesday, 2/25/2015
P-B4: Transmission Networks: MSM: Tuesday, 2/24/2015
P-B5: Next Generation of Next-Generation Sequencing: Thursday, 2/26/2015

C: Pathogenesis—Human Studies and Animal Models
P-C1: The Gut Microbiome: Tuesday, 2/24/2015
P-C2: The Mucosa in HIV/SIV Pathogenesis: Tuesday, 2/24/2015
P-C3: Innate and Unconventional T-Cell Responses: Wednesday, 2/25/2015
P-C4: Monocytes, Dendritic Cells, and Neutrophils: Wednesday, 2/25/2015
P-C5: Studies of HIV-Exposed Uninfected Individuals: Tuesday, 2/24/2015
P-C6: Host Factors in HIV Pathogenesis: Tuesday, 2/24/2015
P-C7: HIV/CMV Interactions in Transmission and Pathogenesis: Thursday, 2/26/2015
P-C8: Aging and Immune Senescence: Thursday, 2/26/2015
P-C9: Immune Pathogenesis of IRIS: Thursday, 2/26/2015
P-C10: Immune Activation and HIV Pathogenesis: Wednesday, 2/25/2015
P-C11: Manipulating Immune Activation: Wednesday, 2/25/2015
P-C12: Pathogenesis in Lymph Nodes: Thursday, 2/26/2015
P-C13: Dissecting Pathogenesis Through In Vitro Studies: Thursday, 2/26/2015
P-C14: Dissecting Pathogenesis Through In Vivo Studies: Thursday, 2/26/2015

E: Host Immune Responses to Infection, Vaccines, and Immunotherapy
P-E1: The Effect of HIV Infection on B Cells: Tuesday, 2/24/2015
P-E2: The Envelope/Antibody Dynamic: Tuesday, 2/24/2015
P-E3: New Approaches to Immunostimulation: Wednesday, 2/25/2015
P-E4: Cellular Immune Response to HIV: Thursday, 2/26/2015

F: HIV Persistence, Reservoirs, Latency, Eradication, including Gene Therapy
P-F1: Immune-Based Strategies in Latency: Tuesday, 2/24/2015
P-F2: Viral Reservoir Dynamics During ART: Thursday, 2/26/2015
P-F3: Cellular Factors of Latency: Thursday, 2/26/2015
P-F4: Dynamics of Latency and Reactivation: Wednesday, 2/25/2015
P-F5: Gene Editing: Wednesday, 2/25/2015
P-F6: HDAC Inhibitors: Tuesday, 2/24/2015
P-F7: Pharmacologic Latency-Reactivation Agents: Tuesday, 2/24/2015
P-F8: Latency Models and Assays: Wednesday, 2/25/2015
P-F9: Stem Cell Transplantation: Wednesday, 2/25/2015

G: Neuropathogenesis
P-G1: CNS Reservoirs: Tuesday, 2/24/2015
P-G2: Optimizing ART for HAND Treatment and Prevention: Tuesday, 2/24/2015
P-G3: Neurologic Disorders in Resource-Limited Settings: Wednesday, 2/25/2015
P-G4: HAND Genetics: Thursday, 2/26/2015
P-G5: HAND Diagnosis and Predictors: Tuesday, 2/24/2015
P-G6: Inflammation and Markers of Brain Injury in HAND: Thursday, 2/26/2015
P-G7: Aging and Cognitive Decline: Wednesday, 2/25/2015
P-G8: Mitochondrial Dysfunction in HAND and Depression: Thursday, 2/26/2015
P-G9: Neuropathogenesis Mechanisms: Thursday, 2/26/2015

H: Clinical Pharmacology
P-H1: Pharmacokinetics, Pharmacodynamics, and Adherence: Tuesday, 2/24/2015
P-H2: Pharmacogenomics: Tuesday, 2/24/2015
P-H3: Drug-Drug Interactions: Tuesday, 2/24/2015
P-H4: Pharmacokinetics in Compartments and Reservoirs and of Novel Formulations: Thursday, 2/26/2015
P-H5: New Technologies in Assessing Drug Interactions and Systemic and Intracellular Pharmacology: Thursday, 2/26/2015

I: Antiretroviral Therapy: Preclinical Studies
P-I1: Drug Development: Wednesday, 2/25/2015

J: Antiretroviral Therapy: Randomized Clinical Trials
P-J1: ART: Recent Perspectives: Tuesday, 2/24/2015

K: Antiretroviral Therapy: Observational Studies
P-K1: ART: Adherence, Adherence, Adherence: Tuesday, 2/24/2015
P-K2: ART: Monitoring and Biomarkers: Tuesday, 2/24/2015
P-K3: ART: Immunologic Response?The Good and The Bad: Wednesday, 2/25/2015
P-K4: ART: Mortality: Wednesday, 2/25/2015

L: HIV Drug Resistance
P-L1: HIV Drug Resistance: Mechanisms and Mutations: Thursday, 2/26/2015
P-L2: HIV Subtypes and Resistance: Thursday, 2/26/2015
P-L3: Transmitted HIV Drug Resistance: Assessing the Threat: Thursday, 2/26/2015
P-L4: HIV Drug Resistance: Global Perspective and Clinical Implications: Thursday, 2/26/2015

M: HIV Diagnostics
P-M1: Nucleic-Acid–Based Detection of HIV: Tuesday, 2/24/2015
P-M2: Comparison of HIV Incidence Assays: Wednesday, 2/25/2015
P-M3: HIV Detection, Tropism, and CD4 Measurement: Wednesday, 2/25/2015

N: Hepatitis Viruses
P-N1: Natural History and Prognosis of HCV Infection: Tuesday, 2/24/2015
P-N2: HCV Therapy: Observations From Cohort Studies: Tuesday, 2/24/2015
P-N3: Treatment of HCV with DAAs: Short-Term Costs and Long-Term Benefits: Tuesday, 2/24/2015
P-N4: HCV: Getting the Drugs to Those Who Need Them: Tuesday, 2/24/2015
P-N5: HCV: Epidemiology and Case Detection: Wednesday, 2/25/2015
P-N6: Acute HCV Infection: Wednesday, 2/25/2015
P-N7: Immunopathogenesis of HCV Infection: Wednesday, 2/25/2015
P-N8: HCV Therapeutics: Preclinical Observations and Clinical Trials of DAAs: Thursday, 2/26/2015
P-N9: Mental Health and Treatment Adherence with Direct-Acting Antivirals: Thursday, 2/26/2015
P-N10: HCV: Resistance to Antiviral Agents: Thursday, 2/26/2015
P-N11: Other Hepatitis Viruses: HBV, HDV, HEV: Thursday, 2/26/2015

O: HIV-Related and Non–HIV-Related Malignancies
P-O1: HPV Infections and Cancers: Tuesday, 2/24/2015
P-O2: AIDS-Related Cancers: Lymphoma and KS: Wednesday, 2/25/2015
P-O3: Cancer and Cancer Risk in HIV Subpopulations and Lung Cancer: Thursday, 2/26/2015

P: Cardiovascular Complications of HIV Infection and Antiretroviral Therapy
P-P1: Cardiovascular Disease Outcomes: Tuesday, 2/24/2015
P-P2: Dyslipidemia: Mediators and Treatment: Wednesday, 2/25/2015
P-P3: ART: Cardiovascular Risk and Hypertension: Wednesday, 2/25/2015
P-P4: What Predicts Risk for CVD in HIV? Tuesday, 2/24/2015
P-P5: Cardiovascular Risk Prediction: Wednesday, 2/25/2015
P-P6: Biomarkers and Atherosclerosis: Tuesday, 2/24/2015
P-P7: Endothelial Functions and Cerebral Vasoreactivity: Tuesday, 2/24/2015

Q: Other Complications of HIV Infection and Antiretroviral Therapy
P-Q1: Inflammation: Biomarkers and Relationship to Outcomes: Tuesday, 2/24/2015
P-Q2: Bone Metabolism and ART: Mechanisms and Outcomes: Tuesday, 2/24/2015
P-Q3: Bone Disease: Mechanisms of Bone Loss and Fracture Risk: Tuesday, 2/24/2015
P-Q4: Measuring Bone Density: Tuesday, 2/24/2015
P-Q5: Fat Without Borders: Metabolic Complications in Resource-Limited Settings: Wednesday, 2/25/2015
P-Q6: Aging: Frailty, Telomeres, and mtDNA: Tuesday, 2/24/2015
P-Q7: Diabetes and Other Endocrine Disorders: Tuesday, 2/24/2015
P-Q8: Renal Dysfunction: ART and Biomarkers: Thursday, 2/26/2015
P-Q9: Renal Transplantation: Long-Term Outcomes: Thursday, 2/26/2015
P-Q10: Pulmonary Disease: Thursday, 2/26/2015
P-Q11: Body Composition and Risk Factors for Abnormalities: Thursday, 2/26/2015
P-Q12: Complications: Liver Disease Without Viral Hepatitis: Thursday, 2/26/2015
P-Q13: Depression and Alcohol Use Disorders: Thursday, 2/26/2015

R: Tuberculosis and Other Opportunistic Infections
P-R1: Immune Reconstitution Inflammatory Syndrome in Opportunistic Infections: Tuesday, 2/24/2015
P-R2: T-Cell Responses to Tuberculosis Infection: Tuesday, 2/24/2015
P-R3: TB Diagnostic Challenges: Tuesday, 2/24/2015
P-R4: TB Adverse Events, Recurrence, and Mortality: Tuesday, 2/24/2015
P-R5: Cryptococcal Meningitis: Host Response, Treatment, and Outcomes: Thursday, 2/26/2015
P-R6: Syphilis and HIV Coinfection: Tuesday, 2/24/2015
P-R7: Opportunistic Infections: Odds and End Organs: Tuesday, 2/24/2015

S: HIV in Women and Women's Health
P-S1: Access and Engagement: Thursday, 2/26/2015
P-S2: Cervical Sampling, Shedding, and Outcomes: Tuesday, 2/24/2015
P-S3: Hormonal Contraception: Thursday, 2/26/2015

T: Maternal/Fetal HIV
P-T1: How Fast? How Often? Achieving Viral Suppression in Pregnant and Postpartum Women: Tuesday, 2/24/2015
P-T2: Rates and Risks of MTCT and HIV-Free Survival: Tuesday, 2/24/2015
P-T3: Option B+: Retention and Transmission: Tuesday, 2/24/2015
P-T4: Health Outcomes of HIV- and ARV-Exposed Infants, Children, and Youth: Thursday, 2/26/2015
P-T5: Coinfections Among HIV-Exposed Infants and Children: Thursday, 2/26/2015
P-T6: ART Adherence, Adverse Effects, and Retention Among Pregnant Women and Infants: Tuesday, 2/24/2015
P-T7: Pharmacokinetics and Safety of ART During Pregnancy: Tuesday, 2/24/2015
P-T8: Planning and Preventing Pregnancy: Tuesday, 2/24/2015
P-T9: Mechanisms of MTCT and Maternal/Infant Health: Thursday, 2/26/2015
P-T10: Immune Mechanisms in MTCT: Tuesday, 2/24/2015
P-T11: PMTCT-Associated Drug Resistance in Women and Infants: Tuesday, 2/24/2015

U: Pediatrics and Adolescents
P-U1: HIV Diagnosis in Infants and Children: Tuesday, 2/24/2015
P-U2: Early ART and HIV Persistence: Tuesday, 2/24/2015
P-U3: Treatment Outcomes Among Children and Youth With HIV: Wednesday, 2/25/2015
P-U4: Treatment and Monitoring Strategies in Children: Wednesday, 2/25/2015
P-U5: Determinants of Disease Progression in Children: Tuesday, 2/24/2015
P-U6: Complications of HIV and ART: Pulmonary and Cardiovascular Outcomes: Thursday, 2/26/2015
P-U7: Complications of HIV and ART: Bones, Brains, and Kidneys: Thursday, 2/26/2015
P-U8: Tuberculosis and Other Coinfections in Children With HIV: Wednesday, 2/25/2015
P-U9: Responses to Vaccines in Children: Tuesday, 2/24/2015
P-U10: Pharmacokinetics, Safety, and Efficacy of ART in Children and Youth: Tuesday, 2/24/2015

V: Prevention and Intervention Studies
P-V1: Postexposure Prophylaxis (PEP): Wednesday, 2/25/2015
P-V2: PrEP and Microbicide Challenge: Thursday, 2/26/2015
P-V3: PrEP: Uptake: Tuesday, 2/24/2015
P-V4: PrEP: Measures and Correlates of Adherence: Tuesday, 2/24/2015
P-V5: PrEP: Evaluating Potential Harm: Wednesday, 2/25/2015
P-V6: HIV Prevention, Miscellaneous: Thursday, 2/26/2015

W: Epidemiology
P-W1: HIV Testing and the Continuum of Care in the Industrialized World: Tuesday, 2/24/2015
P-W2: HIV Testing and the Continuum of Care in the Developing World: Tuesday, 2/24/2015
P-W3: Risk Factors for Transmission in MSM: Wednesday, 2/25/2015
P-W4: Transmission Through Needles and Heterosexual Contact: Wednesday, 2/25/2015
P-W5: Incidence and Prevalence of HIV Infection, Including Acute HIV: Thursday, 2/26/2015
P-W6: Disease Progression, Morbidity, and Mortality: Thursday, 2/26/2015
P-W7: HIV Stigma: Thursday, 2/26/2015
P-W8: Serosorting and Seroadaptive Behavior: What's Your Position? Thursday, 2/26/2015

X: Health Care Delivery and Health Systems
P-X1: Paying for Care: Tuesday, 2/24/2015
P-X2: Linkage to and Retention in Care: Wednesday, 2/25/2015
P-X3: Guidelines and Their Implementation: Thursday, 2/26/2015

Y: Implementation Science
P-Y1: Male Circumcision: Risk, Innovation, and Scale-Up: Thursday, 2/26/2015
P-Y2: Linkage to Care and ART Initiation: Wednesday, 2/25/2015
P-Y3: HIV Testing: Innovations and Scale-Up: Wednesday, 2/25/2015

Z: Population and Economic Modeling
P-Z1: Costs and Cost Effectiveness: Tuesday, 2/24/2015
P-Z2: Modeling HIV Epidemiology: Wednesday, 2/25/2015
P-Z3: Modeling the Impact of HIV Interventions: Thursday, 2/26/2015

POSTER LISTINGS, BY CATEGORY

TUESDAY, FEBRUARY 24, 2015

Session P-A1 Poster Session — Poster Hall
2:30 pm – 4:00 pm

Cellular Innate Immunity

183 STAT5 Inhibition Reduces HIV-1 Infection and TLR7/8 Responses in Human Macrophages
Sofia Appelberg[1]; Carla N. Mavian[1]; Julie C. Williams[1]; Philip Lichlyter[1]; John Sleasman[2]; Maureen M. Goodenow[2]
[1]University of Florida, Gainesville, FL, US; [2]Duke University, Durham, NC, US

184 Regulation of the Innate Immune Sensing of HIV by the Viral Capsid and the Cytosolic DNA Sensor cGAS
Nicolas Manel
Institut Curie, Paris, France

185 cGAS Induced Type I IFN Responses in Dendritic Cells From HIV Elite Controllers
Enrique Martin-Gayo[1]; Jacqueline Cronin[1]; Zhengyu Ouyang[1]; Taylor Hickman[1]; John Trombetta[2]; Florencia Pereyra[1]; Bruce Walker[1]; Alex Shalek[1]; Mathias Lichterfeld[3]; Xu Yu[1]
[1]Ragon Institute of MIT, MGH and Harvard, Boston, MA, US; [2]MIT Institute for Medical Engineering & Science, Boston, MA, US; [3]Massachusetts General Hospital, Boston, MA, US

186 Characterization of Interferon-α Subtypes in the LPAC Model
Michael Harper[1]; Kathrin Gibbert[2]; Eric Lee[1]; Kejun Guo[1]; Stephanie Dillon[1]; Martin McCarter[3]; Ulf Dittmer[2]; Cara C. Wilson[1]; Mario Santiago[1]
[1]University of Colorado Anschutz Medical Campus, Denver, CO, US; [2]University of Duisburg-Essen, Essen, Germany; [3]University of Colorado Anschutz Medical Campus, Aurora, CO, US

187 HIV Vpu Inhibits NF-kB Activity but Does Not Interfere With Interferon Regulatory Factor 3
Lara Manganaro; Elisa de Castro; Ana Maestre; Adolfo Garcia-Sastre; Ana Fernandez-Sesma; Viviana A. Simon
Icahn School of Medicine at Mount Sinai, New York, NY, US

188 HIV-1 Exploits CD169 to Evade IFNα-Induced Antiviral State in Myeloid Cells
Hisashi Akiyama[1]; Nora Ramirez[1]; Gregory Gibson[2]; Simon Watkins[2]; Zandrea Ambrose[2]; Rahm Gummuluru[1]
[1]Boston University School of Medicine, Boston, MA, US; [2]University of Pittsburgh School of Medicine, Pittsburgh, PA, US; [3]University of Pittsburgh School of Medicine, Pittsburgh, PA, US

189 Interferon-Induced Transmembrane Proteins (IFITMs) Antagonize Postintegration Replication of HIV but Are Overcome by Viral Membrane Accessory Proteins
Wingyiu Lee; Ifrah Omar; Richard D. Sloan
Queen Mary University of London, London, United Kingdom

190 HSV-1-Induced Enhancement of HIV-1 Replication Is Dependent on Decrease in IFITM3 Levels
Viviane Andrade[1]; Milene Miranda[2]; Mario Stevenson[1]; Thiago M. Souza[2]
[1]University of Miami, Miami, FL, US; [2]Oswaldo Cruz Foundation, Rio de Janeiro, Brazil

191 Characterization of the Activity of an Innate Immunity Protein, the Apolipoprotein L6
Nitisha Pyndiah[1]; Angela Ciuffi[1]; Amalio Telenti[2]
[1]Institute of Microbiology, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland; [2]J Craig Venter Institute, San Diego, CA, US

192 HIV and SIV Inhibition by RNA-Associated Early Stage Antiviral Factor (REAF)
Aine McKnight
Queen Mary University of London, London, United Kingdom

193 Translational Control of APOBEC3G/F Restriction Factors by the HIV-1 Vif Protein
Camille Libre[1]; Santiago X. Guerrero[2]; Julien Batisse[1]; Roland Marquet[1]; Jean-Christophe Paillart[1]
[1]IBMC CNRS, Strasbourg, France; [2]Centre for Genomic Regulation, Barcelona, Spain

194 Evidence for Lentivirus-Driven Evolution of APOBEC3C
Cristina Wittkopp; Michael Emerman
Fred Hutchinson Cancer Research Center, Seattle, WA, US

195 Reevaluation of the Role of the Small Host Cell GTPase Rab6 in the HIV-1 Replication Cycle
Isaac Zentner; Simon Cocklin
Drexel University College of Medicine, Philadelphia, PA, US

WEDNESDAY, FEBRUARY 25, 2015

Session P-A2 Poster Session — Poster Hall
2:30 pm – 4:00 pm

Nucleus Entry, Integration, and Export

196 The Mutated Form of Transportin 3 From Patients With Limb-Girdle Muscular Dystrophy 1F Hijacks Wild-Type Transportin 3 and Interferes With CPSF6 Subcellular Localization, Impairing HIV-1 Nuclear Entry
Sara Rodriguez-Mora[1]; Mayte Coiras[1]; Mercedes Bermejo[1]; Elena Mateos[1]; Ramon Marti[2]; Juan Jesus Vilchez[3]; Antonio Luis Andreu[2]; Jose Alcami[1]
On behalf of the AIDS Immunopathogenesis Unit
[1]Instituto de Salud Carlos III, Madrid, Spain; [2]Vall d'Hebron Institut de Recerca, Barcelona, Spain; [3]Hospital Universitari i Politecnic La Fe, Valencia, Spain

197 Longitudinal Epigenome-Wide Association Study of Pre- and Post-HIV–Infected Subjects
Sophie Limou[1]; George W. Nelson[1]; Elizabeth Binns-Roemer[1]; Jia Li[1]; Fathi Elloumi[1]; James J. Goedert[3]; Cheryl A. Winkler[1]
[1]Frederick National Laboratory Operated by Leidos Biomedical Research, Inc, for the National Cancer Institute, Frederick, MD, US; [2]Frederick National Laboratory Operated by Leidos Biomedical Research, Inc, for the National Cancer Institute, Frederick, MD, US; [3]National Cancer Institute (NCI), Bethesda, MD, US

198 IN Variants Retarget HIV-1 Integration and Are Associated With Disease Progression
Frauke Christ[1]; Jonas Demeulemeester[1]; Zeger Debyser[1]; Rik Gijsbers[1]; Jan De Rijck[1]; Thumbi Ndung'u[2]; Paradise Madlala[1]
[1]KU Leuven, Leuven, Belgium; [2]University of KwaZulu-Natal, Durban, South Africa

199 HIV-1 Integration Sites in Macrophages and CD4$^+$ T Cells Are Distinct
Yik Lim Kok; Valentina Vongrad; Mohaned Shilaih; Herbert Kuster; Roger Kouyos; Huldrych F. Günthard; Karin J. Metzner
University Hospital Zurich, Zurich, Switzerland

200 A Screening for DNA Repair Enzymes That Affect HIV-1 Infection
Noriyoshi Yoshinaga[1]; Yusuke Matsui[1]; Keisuke Shindo[1]; shunichi Takeda[1]; Akifumi Takaori-Kondo[1]
[1]Kyoto University, Kyoto-shi, Japan; [2]Kyoto University, Kyoto-shi, Japan

201 The Activity of HIV-1 Rev/RRE Varies Greatly Between Isolates

Patrick E. Jackson[1]; Denis Tebit[1]; David Rekosh[1]; Marie-Louise Hammarskjold[1]

[1]University of Virginia, Charlottesville, VA, US; [2]University of Virginia, Charlottesville, VA, US

TUESDAY, FEBRUARY 24, 2015

Session P-A3 Poster Session — Poster Hall

2:30 pm – 4:00 pm

SAMHD1

202 A Surprising New Function of SAMHD1 as a Pro-Pathogenic Factor in HIV Infection

Gilad Doitsh; Nicole Galloway; Xin Geng; Isa Monus Arias; Zhiyuan Yang; Warner C. Greene

The J. David Gladstone Institute, University of California San Francisco, San Francisco, CA, US

203 Mapping Vpx and Vpr Specificity in Antagonism of SAMHD1

Chelsea Spragg; Michael Emerman

Fred Hutchinson Cancer Research Center, Seattle, WA, US

204 Differentiation Stimuli Strongly Impact the Ability of Macrophages to Support HIV-1 Replication Due to SAMHD1 Restriction

Ester Ballana[1]; Roger Badia[1]; Eva Riveira-Muñoz[1]; Alba Ruíz[1]; Javier Torres-Torronteras[2]; Bonaventura Clotet[1]; Eduardo Pauls[1]; Ramon Marti[2]; José Esté[1]
HIV Pathogenesis Research Group

[1]IrsiCaixa Institute for AIDS Research, Badalona, Spain; [2]Institut de Recerca Hospital Universitari Vall d'Hebron, Barcelona, Spain

205 Essential Role of Cyclin D3 in dNTP Pool Control and HIV-1 Replication in Macrophages

Ester Ballana[1]; Alba Ruíz[1]; Eduardo Pauls[1]; Javier Torres-Torronteras[2]; Roger Badia[1]; Eva Riveira-Muñoz[1]; Bonaventura Clotet[1]; Ramon Marti[2]; José Esté[1]
HIV Pathogenesis Research Group

[1]IrsiCaixa Institute for AIDS Research, Badalona, Spain; [2]Institut de Recerca Hospital Universitari Vall d'Hebron, Badalona, Spain

206 Low SAMHD1 Expression Renders Activated and Proliferated CD4$^+$ Susceptible to HIV-1

Nabila Seddiki[1]; Nicolas Ruffin[1]; Vedran Brezar[1]; Diana Ayinde[2]; Julian Schulze zur Wiesch[3]; Jan van Lunzen[3]; Olivier Schwartz[2]; Jean-Daniel Lelièvre[1]; Jacques Banchereau[1]; Yves Lévy[1]

[1]Inserm U955 Eq16/UPEC, Créteil, France; [2]Institut Pasteur, Paris, France; [3]University Medical Center, Hamburg-Eppendorf and Heinrich-Pette-Institute, Hamburg, Germany

207 SAMHD1 Partially Blocks Lentiviral Gene Transfer Into Hematopoietic Stem Cells

Duo Li[1]; Erika Schlaepfer[1]; Annette Audigé[1]; Baek Kim[2]; Roberto Speck[1]

[1]University Hospital Zurich, Zurich, Switzerland; [2]Department of Pediatrics Emory School of Medicine, Atlanta, GA, US

THURSDAY, FEBRUARY 26, 2015

Session P-A4 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Enhancers and Inhibitors of Viral Infectivity and Entry

208 Fresh Semen Harbors HIV-Enhancing Amyloids and Decreases the Efficacy of Microbicides

Jan Munch[3]; Onofrio Zirafi[3]; Shariq Usmani[3]; Kyeong-Ae Kim[3]; Frank Kirchhoff[3]; Christopher D. Pilcher[1]; Haichuan Liu[1]; H. Ewa Witkowska[1]; Warner C. Greene[2]; **Nadia R. Roan**[1]

[1]University of California San Francisco, San Francisco, CA, US; [2]The J. David Gladstone Institutes, San Francisco, CA, US; [3]Ulm University Medical Center, Ulm, Germany

209 Semen's HIV Enhancing Activity Is an Individual Characteristic Independent of VL

Christopher D. Pilcher; Teri Liegler; Jason Neidleman; H. Ewa Witkowska; Wendy Hartogensis; Kara Marson; Peter Bacchetti; Frederick M. Hecht; Warner C. Greene; Nadia R. Roan

University of California San Francisco, San Francisco, CA, US

210 Hyaluronan Reduces HIV Infection of CD4+ T Cells and Greatly Enhances HIV Inhibition by Tenofovir

Peilin Li; Katsuya Fujimoto; Lilly Bourguignon; Steven Yukl; Steven Deeks; Philipp Kaiser; Peggy Kim; Diane Havlir; Harry Lampiris; Joseph K. Wong

University of California San Francisco, San Francisco, CA, US

211 Alpha-defensins increase HIV transcytosis: role in STI-mediated enhanced HIV transmission

Kimyata B. Valere[1]; Aprille Rapista[1]; Alison Quayle[2]; Wuyan Lu[3]; Eliseo Eugenin[1]; Theresa Chang[1]

[1]Rutgers University-New Jersey Medical School, Willingboro, NJ, US; [2]University Health Science Center, New Orleans, LA, US; [3]University of Maryland School of Medicine, Baltimore, MD, US

212 The Design and Investigation of Mechanism of Novel Potent HIV-1 Entry Inhibitor SC12

Marina Tuyishime; Simon Cocklin

Drexel University College of Medicine, Philadelphia, PA, US

213 Optimization of vCCL2-Based CXCR4 Inhibitors by Phage Display and Rational Design

Virginie Fievez[1]; Martyna Szpakowska[1]; Karthik Arumugam[1]; Amor Mosbah[2]; Sabrina Deroo[1]; Xavier Dervillez[1]; Pierre-Arnaud Gauthier[1]; Michele Baudy-Floc'h[2]; Carole Devaux[1]; Andy Chevigné[1]

[1]CRP-sante, Laboratory of Retrovirology, 84 Rue Val Fleuri, 1526 Luxembourg, Luxembourg; [2]Université de Rennes 1, UMR CNRS 6226, Avenue du Général Leclerc, 35042 Rennes, France

214 HIV-1 Infection of Female Primary Genital Epithelial Cells After Pseudotyping With HTLV-1: Potential Driver of Sexual Transmission of HIV-1

Yuyang Tang[1]; Alvin George[1]; Oksana Petrechko[1]; Brian Imbiakha[1]; Stephanie Sweet[1]; Yuetsu Tanaka[2]; Franklin Nouvet[1]; James E. Hildreth[1]

[1]University of California Davis, Davis, CA, US; [2]University of the Ryukyus, Nishihara-cho, Japan

WEDNESDAY, FEBRUARY 25, 2015

Session P-A5 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Envelopes, Receptors, and Tropism

215 Evaluation of HIV-1 Clones for Unique Properties Associated With Transmission

Katja Klein[1]; Annette Ratcliff[2]; Gabrielle Nickel[2]; Immaculate Nankya[2]; Mike Lobritz[2]; Yong Gao[2]; Robin Shattock[3]; Eric J. Arts[1]

[1]University of Western Ontario, London, Canada; [2]Case Western Reserve University, Cleveland, OH, US; [3]Imperial College London, London, United Kingdom

216 Selection of HIV Env Mutants With Altered Trimers by EMPIRIC Saturation Mutagenesis

Maria Duenas-Decamp; Li Jiang; Dan Bolon; Paul R. Clapham

University of Massachusetts Medical School, Worcester, MA, US

217 Characterization of HIV-1 Envelopes in Acutely and Chronically Infected Injection Drug Users

Behzad Etemad[1]; Oscar A. Gonzalez[1]; Laura F. White[2]; Oliver B. Laeyendecker[3]; Greg D. Kirk[3]; Shruti Mehta[3]; **Manish Sagar**[1]

[1]Boston University School of Medicine, Boston, MA, US; [2]Boston University, Boston, MA, US; [3]Johns Hopkins University, Baltimore, MD, US

218 Phenotypic Characterization of Transmitted/Founder Virus in HIV-1 Transmission Pairs

Corinna S. Oberle[1]; Beda Joos[1]; Nottania K. Campbell[1]; David Beauparlant[1]; Herbert Kuster[1]; Corinne Schenkel[1]; Peter Rusert[1]; Alexandra Trkola[1]; Karin J. Metzner[1]; Huldrych F. Günthard[1]

[1]University Hospital Zurich, Zurich, Switzerland; [2]Institute of Medical Virology, Zurich, Switzerland

219 HIV Coreceptor Tropism Switching Is Correlated With Binding Affinity to CXCR4

Homero Vazquez[1]; Antoine Chaillon[2]; Douglas D. Richman[3]; Sara Gianella Weibel[1]; Gabriel Wagner[1]; David M. Smith[3]

[1]University of California San Diego, San Diego, CA, US; [2]Inserm UMR U966, Tours, France; [3]Veterans Affairs Medical Center, San Diego, CA, US

220 Selective Cell-Free or Cell-to-Cell HIV-1 Infection by gp41 Cytoplasmic Tail Mutants

Natasha D. Durham[1]; Benjamin K. Chen[1]

[1]Icahn School of Medicine at Mount Sinai, New York, NY, US; [2]Icahn School of Medicine at Mount Sinai, New York, NY, US

221 Analysis of Viral Evolution in the Blood Reveals Potential Insight Into the Evolution of Macrophage Tropism

Maria M. Bednar[1]; LiHua Ping[1]; Kathryn Arrildt[1]; Christa Sturdevant[2]; Sarah B. Joseph[1]; Laura Kincer[1]; Celia LaBranche[2]; David Montefiori[2]; Myron Cohen[3]; Ronald Swanstrom[1]

[1]University of North Carolina, Durham, NC, US; [2]Duke University, Durham, NC, US; [3]University of North Carolina, Chapel Hill, NC, US

222 Mechanistic Differences in Interactions of HIV-1 and HIV-2 With Dendritic Cells

Suzanne D. Kijewski; Hisashi Akiyama; Caitlin Miller; Nora P. Ramirez; Rahm Gummuluru

Boston University School of Medicine, Boston, MA, US

223 Identification of the First Nonhuman Primate CD4 Receptor for T/F HIV-1 Isolates

Nicholas Meyerson[2]; **Amit Sharma**[1]; Gregory Wilkerson[3]; Julie M. Overbaugh[1]; Sara Sawyer[2]

[1]Fred Hutchinson Cancer Research Center, Seattle, WA, US; [2]The University of Texas at Austin, Austin, TX, US; [3]University of Texas, MD Anderson Cancer Center, Bastrop, TX, US

224LB Vpr Increases Env Spikes on Virions to Enhance HIV-1 Replication in Nondividing Myeloid Cells

Tao Zhou[1]; Xianfeng Zhang[2]; **Yonghui Zheng**[1]

[1]Michigan State University, East Lansing, MI, US; [2]Harbin Veterinary Research Institute, Harbin, China

THURSDAY, FEBRUARY 26, 2015

Session P-A6 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Nef Functions

225 Env and Nef Cooperatively Contribute to HIV-1–Induced pDC Activation via CD4-Dependent Mechanisms

Natalia J. Reszka-Blanco[1]; Vijay Sivaraman[1]; Liguo Zhang[2]; Lishan Su[1]

[1]University of North Carolina, Chapel Hill, NC, US; [2]Key Lab of Infection and Immunity, Insitute of Biophysics, Chinese Academy of Science, Beijing, China

226 Naturally Occurring Polymorphisms in HIV-1 Nef Impair Its Functions and Decrease Viral Replication Capacity

Thomas Vollbrecht[2]; Lorelei Bornfleth[1]; Patricia Frohnen[1]; Martha J. Lewis[1]

[1]David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA, US; [2]University of California San Diego (UCSD), La Jolla, CA, US

227 Dynamic Range of Down-Regulation of HIV-1 Entry Receptors by Primary Nef Isolates

Mako Toyoda[1]; Yoko Ogata[1]; Macdonald Mahiti[1]; Florencia Pereyra[3]; Toshiyuki Miura[2]; Bruce Walker[3]; Zabrina L. Brumme[4]; Mark A. Brockman[4]; Takamasa Ueno[1]

[1]Kumamoto University, Kumamoto, Japan; [2]University of Tokyo, Tokyo, Japan; [3]Ragon Institute of MGH, MIT and Harvard University, Cambridge, MA, US; [4]Simon Fraser University, Burnaby, Canada

228 Differential Down-Regulation of HLA Class I Allotypes by HIV-1 Nef Primary Isolates

Macdonald Mahiti[1]; Xiaofei Jia[2]; Mako Toyoda[1]; Francis Mwimanzi[1]; Bruce Walker[3]; Zabrina L. Brumme[4]; Mark Brockman[4]; Yong Xiong[2]; **Takamasa Ueno**[1]

[1]Kumamoto University, Kumamoto, Japan; [2]Yale University, New Haven, CT, US; [3]Ragon Institute of MGH, MIT and Harvard University, Boston, MA, US; [4]Simon Fraser University, Burnaby, Canada

Session P-B1 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Viral Origins and Recombinant Forms

229 Geopolitical Effects in the Epidemiology of HIV-1 Subtype

Gkikas Magiorkinis[2]; Kostantinos Angelis[1]; Ioannis Mamais[1]; Angelos Hatzakis[1]; Jan Albert[3]; Glenn Lawyer[4]; Annemarie Wensing[5]; Charles Boucher[6]; Anne-Mieke Vandamme[7]; **Dimitrios Paraskevis**[1]

[1]University of Athens, Athens, Greece; [2]University of Oxford, Oxford, United Kingdom; [3]Karolinska Institutet, Stockholm, Sweden; [4]Max Planck Institute for Informatics, Saarbrücken, Germany; [5]University Medical Center Utrecht, Utrecht, Netherlands; [6]Erasmus University Medical Center, Rotterdam, Netherlands; [7]KU Leuven, Leuven, Belgium

230 The 2 Phases of HIV-1 Group O Diversification

Marie Leoz[1]; Felix Feyertag[2]; Anfumbom Kfutwah[3]; Philippe Mauclere[4]; Guillaume Lachenal[5]; Florence Damond[6]; Veronique Lemee[1]; Francois Simon[7]; David Robertson[2]; Jean-Christophe Plantier[1]

[1]University Hospital Rouen, Rouen, France; [2]Manchester University, Manchester, United Kingdom; [3]Centre Pasteur du Cameroun, Yaounde, Cameroon; [4]Direction Interarmées du Service de Santé, Noumea, New Caledonia; [5]Université Paris Diderot, Paris, France; [6]APHP CHU Bichat Claude Bernard, Paris, France; [7]APHP CHU Saint Louis, Paris, France

231 Evidence for More Major HIV-1M Lineages From the Early Stages of the HIV-1 Epidemic

Marcel Tongo Passo[1]; Wendy A. Burgers[2]; Eitel Mpoudi-Ngole[3]; Jeffrey Dorfman[1]; Darren P. Martin[4]

[1]International Center for Genetic Engineering and Biotechnology, Cape Town, Cape Town, South Africa; [2]Division of Medical Virology, University of Cape Town, Cape Town, South Africa; [3]Institute of Medical Research and Study of Medicinal Plants (IMPM), Yaoundé, Cameroon, Yaounde, Cameroon; [4]Computational Biology Group, University of Cape Town, Cape Town, South Africa

232 HIV-1/M+O Dual Infections and HIV-MO Recombinants in France From 2004 to 2014

Pierre Cappy[1]; Fabienne De Oliveira[1]; Veronique Lemee[1]; Jean-Louis Gaillard[2]; Laurence Bocquet[3]; Jean-Dominique Poveda[4]; Magali Bouvier[5]; Anne Maillard[6]; **Thomas Mourez**[1]; Jean-Christophe Plantier[1]

[1]Rouen University Hospital, Rouen, France; [2]Ambroise Paré Hospital, Paris, France; [3]Lille University Hospital, Lille, France; [4]CERBA Laboratory, Saint-Ouen L'Aumone, France; [5]Henri Mondor Hospital, Créteil, France; [6]Pontchaillou Hospital, Rennes, France

233 Evidence of Intra-Familial Transmission of an HIV-1 M/O Intergroup Recombinant Virus

Paul Alain T. Ngoupo[1]; Serge Alain Sadeuh-Mba[1]; Fabienne De Oliveira[2]; Valérie Ngono[1]; Laure Ngono[1]; Patrice Tchendjou[4]; Véronique Penlap Mbeng[3]; Richard Njouom[1]; Anfumbom Kfutwah[1]; Jean-Christophe Plantier[2]

[1]Centre Pasteur of Cameroon, Yaounde, Cameroon; [2]Virology, CHU Rouen, Rouen, France; [3]University of Yaounde I, Yaounde, Cameroon; [4]Epidemiology, Centre Pasteur of Cameroon, Yaounde, Cameroon

234 Searching for Rare HIV Strains in Rural Democratic Republic of Congo (2001–2003)

Ana S. Vallari[1]; Carole McArthur[2]; Larry Sthreshley[3]; Catherine Brennan[1]

[1]Abbott Laboratories, Chicago, IL, US; [2]University of Missouri–Kansas City, Kansas City, MO, US; [3]IMA World Health, Kinshasa, Congo (the Democratic Republic of the)

235 Clinical and Virological Characterization of CRF07_BC infection

Szu-Wei Huang[1]; Sheng-Fan Wang[1]; Chih-Hao Lee[1]; Wing-Wai Wong[2]; Hung-Chin Tsai[3]; Chia-Jui Yang[4]; Chin-Tien Wang[5]; Jaang-Jiun Wang[6]; Daniel Kuritzkes[7]; Yi-Ming A. Chen[1]

[1]Kaohsiung Medical University, Kaohsiung City, Taiwan; [2]Taipei Veterans' General Hospital, Taipei, Taiwan; [3]Kaohsiung Veterans' General Hospital, Kaohsiung City, Taiwan; [4]Far Eastern Memorial Hospital, New Taipei City, Taiwan; [5]National Yang-Ming University, Taipei, Taiwan; [6]Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, US; [7]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, US

236 Reconstructing the HIV-1 Epidemics in Burkina Faso Using Early Samples

Gonzalo Yebra[1]; Marcia L. Kalish[2]; Andrew J. Leigh Brown[1]

[1]University of Edinburgh, Edinburgh, United Kingdom; [2]Vanderbilt University, Nashville, TN, US

237 **Neutralizing Antibodies in Humans Infected With Zoonotic Simian Foamy Viruses**

Caroline Lambert[1]; Julie Gouzil[2]; Réjane Rua[1]; Edouard Betsem[3]; Antoine Gessain[1]; **Florence Buseyne**[1]

[1]Institut Pasteur, Paris, France; [2]Ecole Vétérinaire, Maison-Alfort, France; [3]University of Yaounde, Yaounde, Cameroon

TUESDAY, FEBRUARY 24, 2015

Session P-B2 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Defining Epidemiologically Linked Transmission

238 **Large Phylogenetically Linked HIV Cluster in King County, Washington, 2008 to 2014**

Susan E. Buskin[1]; Joshua T. Herbeck[2]; Katelynne M. Gardner Toren[1]; Michelle R. Perry[1]; Amy Bennett[1]; Matthew R. Golden[2]

[1]Public Health—Seattle & King County, Seattle, WA, US; [2]University of Washington, Seattle, WA, US

239 **Reconciling Named Partner and Genetic Partner HIV-1 Transmission Networks in New York City**

Joel O. Wertheim[1]; Sergei L. Kosakovsky Pond[1]; Konrad Scheffler[1]; Davey M. Smith[1]; Sanjay Mehta[1]; Sharmila Shah[2]; Lisa Forgione[2]; Lucia V. Torian[2]

[1]University of California San Diego, San Diego, CA, US; [2]New York City Department of Health and Mental Hygiene, New York, NY, US

240 **Efforts to Characterize Community HIV Transmission Dynamics May Be Critically Dependent on Provision of Both Partner Services and Genetic Sequence Analysis**

Nella L. Green; Christy Anderson; Sergei L. Kosakovsky Pond; Martin Hoenigl; David M. Smith; Sanjay Mehta; Susan Little

University of California San Diego, San Diego, CA, US

WEDNESDAY, FEBRUARY 25, 2015

Session P-B3 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Transmission Clusters

241 **Growth and Geographic Spread of HIV Transmission Clusters, United States, 2007-2012**

Alexandra M. Oster[1]; Joel Wertheim[2]; Ellsworth Campbell[1]; Angela L. Hernandez[1]; Neeraja Saduvala[2]; William M. Switzer[1]; M. Cheryl Ocfemia[1]; Anupama Shankar[1]; H. Irene Hall[1]

[1]US Centers for Disease Control and Prevention (CDC), Decatur, GA, US; [2]ICF International, Atlanta, GA, US

242 **HIV Transmission Networks Among the USA, Mexico, and Central America**

Santiago Avila-Rios[1]; Joel O. Wertheim[2]; Ann M. Dennis[8]; Gustavo Reyes-Terán[1]; Carlos Mejía-Villatoro[3]; Elsa Y. Palou[4]; Guillermo Porras-Cortes[6]; Juan M Pascale[5]; Marvin Manzanero[7]; Sanjay Mehta[2]

[1]National Institute of Respiratory Diseases, Mexico City, Mexico; [2]University of California San Diego (UCSD), San Diego, CA, US; [3]Roosevelt Hospital, Guatemala City, Guatemala; [4]Hospital Escuela Universitario, Tegucigalpa, Honduras; [5]Gorgas Memorial Institute for Health Studies, Panama, Panama; [6]Vivian Pellas Metropolitan Hospital, Managua, Nicaragua; [7]Ministry of Health, Belmopan, Belize; [8]University of North Carolina, Chapel Hill, NC, US

243 **Sexual Networks Across Risk Groups Persistently Contribute to Local Spread of HIV**

Marije Hofstra[1]; Tania Mudrikova[1]; Marieke Pingen[1]; Kristine Koekkoek[1]; Arjan Van Laarhoven[1]; Rob Schuurman[1]; Andy I. Hoepelman[1]; Annemarie M. Wensing[1]

[1]University Medical Center Utrecht, Utrecht, Netherlands; [2]University Medical Center Utrecht, Utrecht, Netherlands

244 **Estimation of HIV-1 Transmission During Recent Infection in Switzerland**

Alex Marzel[1]; Mohaned Shilaih[1]; Wan-Lin Yang[1]; Jürg Böni[2]; Sabine Yerly[3]; Thomas Klimkait[4]; Vincent Aubert[5]; Huldrych F. Günthard[1]; Roger Kouyos[1]
On behalf of the Swiss HIV Cohort Study (SHCS)

[1]Division of Infectious Diseases and Hospital Epidemiology, University Hospital Zurich, Zurich, Switzerland; [2]Swiss National Center for Retroviruses, Zurich, Switzerland; [3]Laboratory of Virology, Geneva, Switzerland; [4]Department of Biomedicine—Petersplatz, Basel, Switzerland; [5]Division of Immunology and Allergy, Lausanne, Switzerland; [6]The Swiss HIV Cohort Study, Zurich, Switzerland

245 **Clustering of Swiss HIV Patients Not Enrolled in the Swiss HIV Cohort Study (SHCS)**

Mohaned Shilaih[1]; Alex Marzel[1]; Jörg Schüpbach[1]; Jürg Böni[1]; Sabine Yerly[2]; Thomas Klimkait[4]; Vincent Aubert[3]; Huldrych F. Günthard[1]; Roger Kouyos[1]
The Swiss HIV Cohort Study (SHCS)

[1]University Hospital Zurich, Zurich, Switzerland; [2]Geneva University Hospital, Geneva, Switzerland; [3]University Hospital Lausanne, Lausanne, Switzerland; [4]University of Basel, Basel, Switzerland; [5]University of Zurich, Zurich, Switzerland

246 **HIV Transmission Network Structure Reveals Characteristics of Bridging Individuals**

Sanjay Mehta; Joel O. Wertheim; Konrad Scheffler; Susan Little; Richard R. Garfein; Sergei L. Kosakovsky Pond; David M. Smith

University of California San Diego, La Jolla, CA, US

247 **Phylodynamic Analysis of HIV Sub-Epidemics in Mochudi, Botswana**

Vladimir Novitsky[1]; Denise Kuehnert[2]; Sikhulile Moyo[3]; Erik van Widenfeldt[3]; Lillian Okui[3]; Max Essex[1]

[1]Harvard School of Public Health, Boston, MA, US; [2]ETH Zürich, Zürich, Switzerland; [3]Botswana-Harvard AIDS Institute Partnership, Gaborone, Botswana

248 **Exploring Transmission Dynamics of HIV in Rural KwaZulu-Natal, Using Phylogenetics**

Eduan Wilkinson[1]; Siva Danaviah[1]; Justen Manasa[1]; Frank Tanser[1]; Kobus Herbst[1]; Deenan Pillay[2]; **Tulio de Oliveira**[1]
On behalf of the PANGEA_HIV Consortium

[1]University of KwaZulu-Natal, Durban, South Africa; [2]University College London, London, United Kingdom

249 **Detecting Changes in Incidence Using Phylogenetic Tools: Simulation-Based Studies Within the PANGEA_HIV Initiative**

Emma B. Hodcroft[1]; Oliver Ratmann[2]; Anne Cori[2]; Mike Pickles[2]; Samantha Lycett[3]; Manon L. Ragonnet-Cronin[1]; Matthew Hall[1]; Andrew J. Leigh Brown[1]; Christophe Fraser[2]
On behalf of the Pangea_HIV Consortium

[1]University of Edinburgh, Edinburgh, United Kingdom; [2]Imperial College London, London, United Kingdom; [3]University of Glasgow, Glasgow, United Kingdom

TUESDAY, FEBRUARY 24, 2015

Session P-B4 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Transmission Networks: MSM

250 **HIV Transmission Among Seattle Adolescents**

Joshua Herbeck[1]; Elizabeth Wolf[1]; Stephen van Rompaey[2]; Mari M. Kitahata[2]; Lisa Frenkel[1]

[1]University of Washington, Seattle, WA, US; [2]Center for AIDS Research, Seattle, WA, US

251 **Characterization of Large Cluster Viral Networks Sustaining the Montreal MSM Epidemic**

Bluma Brenner[2]; Ruxandra-Ilinca Ibanescu[2]; Daniela Moisi[2]; Isabelle Hardy[3]; Jean-Pierre Routy[1]; Joanne Otis[4]; Mark Wainberg[2]; Michel Roger[3]

[1]McGill University, Montréal, Canada; [2]Lady Davis Institute, Montreal, Canada; [3]Université de Montréal, Montreal, Canada; [4]UQAM, Montreal, Canada

252 Sources of HIV-1 Transmission in the Ongoing, Concentrated HIV Epidemic Among Men Having Sex With Men in the Netherlands Between July 1996 and December 2010

Oliver Ratmann[1]; Ard van Sighem[2]; Daniela Bezemer[2]; Alexandra Gavryushkina[3]; Peter Reiss[2]; Frank de Wolf[1]; **Christophe Fraser**[1]

[1]Imperial College London, London, United Kingdom; [2]Stichting HIV Monitoring Foundation, Amsterdam, Netherlands; [3]University of Auckland, Auckland, New Zealand

253 A Direct Comparison of Two Densely Sampled Western European HIV Epidemics: The UK and Switzerland

Manon L. Ragonnet-Cronin[1]; Mohaned Shilaih[2]; Huldrych F. Günthard[2]; Jurg Boni[2]; Sabine Yerly[3]; Valerie Delpech[4]; David Dunn[5]; Roger Kouyos[2]; Andrew J. Leigh Brown[1]
Swiss HIV Cohort Study/UK HIV Drug Resistance Database

[1]University of Edinburgh, Edinburgh, United Kingdom; [2]University Hospital Zurich, Zurich, Switzerland; [3]University Hospital Geneva, Geneva, Switzerland; [4]Public Health England, London, United Kingdom; [5]MRC CTU at UCL, London, United Kingdom

THURSDAY, FEBRUARY 26, 2015

Session P-B5 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Next Generation of Next-Generation Sequencing

254 Present Applications of a High-Throughput, Single Measure HIV Genomic Incidence Assay

Sung Yong Park[1]; Tanzy Love[2]; Nolan Goeken[1]; Robert Bolan[3]; Alan S Perelson[4]; Michael Dube[1]; **Ha Youn Lee**[1]

[1]Keck School of Medicine at University of Southern California, Los Angeles, CA, US; [2]University of Rochester School of Medicine and Dentistry, Rochester, CA, US; [3]Los Angeles Gay and Lesbian Center, Los Angeles, CA, US; [4]Los Alamos National Laboratory, Los Alamos, CA, US

255 A Comprehensive Analysis of Primer IDs to Study Heterogenous HIV-1 Populations

David Seifert[1]; Armin Töpfer[1]; Francesca Di Giallonardo[2]; Stefan Schmutz[2]; Huldrych F. Günthard[2]; Volker Roth[3]; Niko Beerenwinkel[1]; Karin J. Metzner[2]

[1]ETH Zurich, Basel, Switzerland; [2]University Hospital Zurich, Zurich, Switzerland; [3]University of Basel, Basel, Switzerland

256 Near Full Length HIV-1 Sequencing to Understand HIV Phylodynamics in Africa in Real Time

Siva Danaviah; Justen Manasa; Eduan Wilkinson; Sureshnee Pillay; Zandile Sibisi; Sthembiso Msweli; Deenan Pillay; **Tulio de Oliveira**

University of KwaZulu-Natal, Durban, South Africa

257 Pan-HIV Next-Gen Sequencing Strategy for Viral Surveillance

Michael G. Berg[1]; Julie Yamaguchi[1]; Elodie Alessandri-Gradt[2]; Jean-Christophe Plantier[2]; Catherine Brennan[1]

[1]Abbott Laboratories, Abbott Park, IL, US; [2]Virology Unit, National Reference for HIV, Rouen, France

258 PCR-Free Full Genome Characterization of Diverse HIV-1 Strains by Nextgen Sequencing

Viswanath Ragupathy[1]; Feng Gao[2]; Ana Sanchez[2]; Marco Schito[3]; Thomas Denny[2]; Michael Busch[4]; Jiangqin Zhao[1]; Christelle Mbondji[1]; SaiVikram Vemula[1]; Indira Hewlett[1]

[1]US Food and Drug Administration, Silver Spring, MD, US; [2]Duke Human Vaccine Institute and Departments of Medicine, Duke University Medical Center, Durham, NC, US; [3]Henry Jackson Foundation, DAIDS, NIAID, Bethesda, MD, US; [4]Blood Systems Research Institute/University of California San Francisco, San Francisco, CA, US

259 Full-Length Env Deep Sequencing in a Donor With Broadly Neutralizing V1/V2 Antibodies

Ben Murrell[1]; Melissa Laird[2]; Elise Landais[3]; Caroline Ignacio[1]; Ellen Paxinos[2]; Pham Phung[4]; Sergei L. Kosakovsky Pond[1]; Douglas D. Richman[1]; Pascal Poignard[3]; Davey M. Smith[1]

[1]University of California San Diego, La Jolla, CA, US; [2]Pacific Biosciences, Menlo Park, CA, US; [3]The International AIDS Vaccine Initiative Neutralizing Antibody Center, La Jolla, CA, US; [4]LabCorp, South San Francisco, CA, US

TUESDAY, FEBRUARY 24, 2015

Session P-C1 Poster Session — Poster Hall

2:30 pm – 4:00 pm

The Gut Microbiome

260 Functional Profiling of the Gut Microbiome in HIV Infection

Yolanda Guillén; Marc Noguera-Julian; Muntsa Rocafort; Mariona Parera; Maria Casadellà; Isabel Bravo; Josep Coll; Julià Blanco; Bonaventura Clotet; Roger Paredes
MetaHIV Study Group

IrsiCaixa AIDS Res Inst, Hosp Univ Germans Trias i Pujol, Univ Autònoma de Barcelona, Badalona, Spain

261 Gut Microbiota Correlates with HIV-1 Control and Immune Status

Muntsa Rocafort; Marc Noguera-Julian; Yolanda Guillén; Mariona Parera; Maria Casadellà; Isabel Bravo; Josep Coll; Julià Blanco; Bonaventura Clotet; Roger Paredes
MetaHIV-Pheno Study Group

IrsiCaixa AIDS Res Inst, Hosp Univ Germans Trias i Pujol, Univ Autònoma de Barcelona, Badalona, Spain

262 Butyrate Reduces Pathobiont-Associated HIV-1 Infection and Activation of Gut T Cell

Jon Kibbie; Stephanie Dillon; Eric Lee; Charles Robertson; Daniel N. Frank; Martin McCarter; Cara C. Wilson

University of Colorado Anschutz Medical Campus, Aurora, CO, US

263 Maraviroc Does Not Induce Changes in the Gut Microbiome of HIV-Infected Individuals

Andrej Vitomirov; David M. Smith; Susanna R. Var; Maile Karris; Parris Jordan; Douglas D. Richman; Susan Little; Josué Pérez-Santiago

University of California San Diego, La Jolla, CA, US

264 Fecal Microbiota of HIV Controllers Is Similar to That of Non–HIV-Infected Individuals

Selma N. Alva Hernández; Sandra M. Pinto Cardoso; Norma Téllez; Akio Murakami-Ogasawara; Gustavo Reyes-Terán

National Institute of Respiratory Diseases, Research Center in Infectious Diseases, Mexico City, Mexico

265 Impact of 2 Antiretroviral Regimens on Fecal Microbial Diversity and Composition

Sandra M. Pinto Cardoso; Selma N. Alva Hernández; Norma Téllez; Akio Murakami-Ogasawara; Gustavo Reyes-Terán

National Institute of Respiratory Diseases, Mexico City, Mexico

266 Targeting Gut Dysbiosis With Prebiotics and Glutamine in HIV-Infected Subjects

Sergio Serrano-Villar[1]; Jorge Vázquez-Castellanos[2]; Alejandro Vallejo[1]; Sara Ferrando-Martínez[4]; Talía Sainz[3]; Mar Vera[5]; Santiago Moreno[1]; Andrés Moya[2]; María José Gosalbes[2]; Vicente Estrada[6]

[1]University Hospital Ramón y Cajal, Madrid, Spain; [2]FISABIO-Salud Pública, Valencia, Spain; [3]University Hospital La Paz, Madrid, Spain; [4]University Hospital Virgen del Rocío, Sevilla, Spain; [5]Centro Sandoval, Madrid, Spain; [6]University Hospital Clínico San Carlos, Madrid, Spain

Session P-C2 Poster Session — Poster Hall

2:30 pm – 4:00 pm

The Mucosa in HIV/SIV Pathogenesis

267 Impact of Mucosal Immunity and HIV Persistence on CD4/CD8 Ratio After ART Initiation

Sergio Serrano-Villar[1]; Talía Sainz[2]; Tae Wook-Chun[3]; Netanya S. Utay[5]; Zhong-Min Ma[4]; Basile Siewe[6]; Steven Deeks[7]; Richard Pollard[4]; Christopher Miller[4]; David Asmuth[4]

[1]University Hospital Ramón y Cajal, Madrid, Spain; [2]University Hospital La Paz, Madrid, Spain; [3]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD, US; [4]University of California Davis, Davis, CA, US; [5]University of Texas, Galveston, TX, US; [6]Rush University Medical Center, Chicago, IL, US; [7]University of California San Francisco, San Francisco, CA, US

268 Monocyte/Macrophage Activation and Recruitment to Mucosal Sites in SIV Pathogenesis

Jan Kristoff[1]; Jenny Stock[1]; Tianyu He[1]; Bruno Andrade[2]; Benjamin Policicchio[1]; Alan Landay[3]; Ivo Francischetti[2]; Cristian Apetrei[1]; Irini Sereti[2]; **Ivona Pandrea**[1]

[1]University of Pittsburgh, Pittsburgh, PA, US; [2]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD, US; [3]Rush University, Chicago, IL, US

269 Rectal Tenofovir Gel Usage Is Associated With Changes in the Mucosal Proteome

Adam Burgener[1]; Laura Romas[1]; Kenzie Birse[1]; Kenneth H. Mayer[3]; Irma Febo[5]; Ross Cranston[2]; Alex Carbarballo-Dieguez[4]; Ian McGowan[2]

[1]University of Manitoba, Winipeg, Canada; [2]University of Pittsburgh, Pittsburgh, PA, US; [3]Harvard Medical School, Boston, MA, US; [4]Columbia University, New York, NY, US; [5]University of Puerto Rico, San Juan, US

270 Links Between Systemic and Mucosal Immunity in Treated HIV Infection

Talía Sainz[1]; Sergio Serrano-Villar[2]; Gregory Melcher[3]; Zhong-Min Ma[3]; Christopher Miller[3]; Netanya S. Utay[4]; Basile Siewe[5]; Paolo Troia-Cancio[3]; Elizabeth Sinclair[6]; David Asmuth[3]

[1]Hospital Universitario Gregorio Marañón, Madrid, Spain; [2]Hospital Ramon y Cajal, Madrid, Spain; [3]University of California Davis, Davis, CA, US; [4]University of Texas Medical Branch, Galveston, TX, US; [5]Rush University Medical Center, Chicago, IL, US; [6]University of California San Francisco (UCSF), San Francisco, CA, US

271 No Impact of Early Intensified Antiretroviral Therapy on Gut Immune Reconstitution

Connie J. Kim[1]; Rodney Rousseau[2]; Colin Kovacs[3]; Sanja Huibner[2]; Gabor Kandel[4]; Erika Benko[3]; Kamnoosh Shahabi[2]; Tae Wook Chun[5]; Mario Ostrowski[2]; Rupert Kaul[2]

[1]Toronto General Hospital, Toronto, Canada; [2]University of Toronto, Toronto, Canada; [3]Maple Leaf Medical Clinic, Toronto, Canada; [4]St. Michael's Hospital, Toronto, Canada; [5]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD, US

272 Altered Properties of Mucosal NK Cell Subsets During Acute HIV-1 Infection

Alexandra Schuetz[1]; Yuwadee Phuang-Ngern[1]; Eugene Kroon[1]; Rungsun Rerknimitr[3]; Nitiya Chomchey[2]; Nittaya Phanuphak[2]; Merlin L. Robb[4]; Jerome H. Kim[4]; Mark de Souza[2]; Jintanat Ananworanich[4]

RV254/SEARCH 010 and RV304/SEARCH 013 Study Groups

[1]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand; [2]Thai Red Cross AIDS Research Center, Bangkok, Thailand; [3]Chulalongkorn University, Bangkok, Thailand; [4]US Military HIV Research Program, Silver Spring, MD, US

273 Loss of Cervical Gamma Delta 1 T cells in HIV-Infected Women

Natasa Strbo[1]; Maria L. Alcaide[1]; Laura Romero[1]; Hector Bolivar[1]; Deborah L. Jones[1]; Eckhard R. Podack[1]; Margaret A. Fischl[1]

[1]University of Miami, Miami, FL, US; [2]University of Miami, Miami, FL, US

274 T Regulatory Cells Disrupt the CCL20-CCR6 Axis Driving Th17 Homing to the Gut

Claire Loiseau[1]; Mary Requena[1]; Michelle Cazabat[1]; Nicolas Carrere[2]; Bertrand Suc[2]; Bruno Marchou[2]; Jacques Izopet[1]; Pierre Delobel[1]

[1]Inserm, Toulouse, France; [2]Centre Hospitalier Universitaire de Toulouse, Toulouse, France

WEDNESDAY, FEBRUARY 25, 2015

Session P-C3 Poster Session **Poster Hall**

2:30 pm – 4:00 pm

Innate and Unconventional T-Cell Responses

275 Effect of KIR2D-Mediated Immunity on Clinical Outcome Among CRF01_AE-Infected Thais

Masahiko Mori[1]; Nuanjun Wichukchinda[2]; Reiko Miyahara[1]; Archawin Rojanawiwat[2]; Panita Pathipvanich[3]; Toshiyuki Miura[1]; Michio Yasunami[1]; Koya Ariyoshi[1]; Pathom Sawanpanyalert[2]

[1]Institute of Tropical Medicine, Nagasaki University, Nagasaki City, Japan; [2]Ministry of Public Health, Nonthaburi, Thailand; [3]Day Care Centre, Lampang Hospital, Lampang, Thailand

276 HLA-KIR-Associated Sites in Gag and Their Effects on Clinical Outcome in Thailand

Masahiko Mori[1]; Nuanjun Wichukchinda[2]; Reiko Miyahara[1]; Archawin Rojanawiwat[2]; Panita Pathipvanich[3]; Toshiyuki Miura[1]; Michio Yasunami[1]; Koya Ariyoshi[1]; Pathom Sawanpanyalert[2]

[1]Institute of Tropical Medicine, Nagasaki University, Nagasaki City, Japan; [2]Ministry of Public Health, Nonthaburi, Thailand; [3]Day Care Centre, Lampang Hospital, Lampang, Thailand

277 In KIR3DL1/S1 Heterozygotes Are KIR3DL1 and KIR3DS1 Co-Dominantly Expressed?

Zahra Kiani[1]; Nicole F. Bernard[1]; Julie Bruneau[2]

[1]McGill University, Montreal, Canada; [2]Centre de Recherche du Centre Hospitalier de l'Universite de Montreal, Montreal, Canada

278 Disruption of Innate-Like Unconventional T-Cell Subsets in HIV-Infected Children

Alka Khaitan[1]; Adam Kravietz[1]; Ilmet Tiina[1]; Mussa Mwamzuka[2]; Fatma Marshed[2]; Cihan Tastan[1]; Aabid Ahmed[2]; Bill Borkowsky[1]; Derya Unutmaz[1]

[1]New York University School of Medicine, New York, NY, US; [2]Bomu Hospital, Mombasa, Kenya; [3]New York University School of Medicine, New York, NY, US

279 HIV-1 Alters Innate Immune Response to BCG, Which Differs From SIV Infected Mangabeys

Melanie Gasper; David Sherman; **Donald Sodora**

Seattle Biomed, Seattle, WA, US

280 High-Level Replication Allows SHIVs to Overcome the Macaque Interferon Response

David F. Boyd; Amit Sharma; Julie M. Overbaugh

Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US

281 Elevated IFN-γ in HIV Patients Using a Novel Assay for Adaptive and Innate Immunity

Michelle K. Yong[1]; Paul Cameron[1]; Tim Spelman[2]; Julian Elliott[1]; Christopher Fairley[4]; Jeffrey Boyle[3]; Misato Miyamasu[3]; Sharon R. Lewin[1]

[1]Monash University/Alfred Hospital, Melbourne, Australia; [2]Burnet Institute, Melbourne, Australia; [3]Qiagen, Melbourne, Australia; [4]Melbourne Sexual Health Centre, Melbourne, Australia

282 TLR8 Regulation of LILRA3 Is Abrogated in HIV Infection and Correlates to CD4 Counts and Virus Loads

Hui Zhi Low; Gerrit Ahrenstorf; Torsten Witte

Hannover Medical School, Hannover, Germany

Session P-C4 Poster Session **Poster Hall**

2:30 pm – 4:00 pm

Monocytes, Dendritic Cells, and Neutrophils

283 Siglec-1 on Monocytes From Untreated HIV-1–Infected Patients Enhances HIV-1 Transfer

Maria Pino; Susana Benet; Itziar Erkizia; Judith Dalmau; Dan Ouchi; Bonaventura Clotet; Javier Martínez-Picado; Nuria Izquierdo-Useros

IrsiCaixa Institute for AIDS Research, Badalona, Spain

284 Soluble CD40 Ligand Contributes to Dendritic Cell Mediated T-Cell Dysfunction

Elizabeth A. Miller; Ramya Gopal; Vanessa Valdes; Jeffrey S. Berger; Nina Bhardwaj; **Meagan O'Brien**

Icahn School of Medicine at Mount Sinai, New York, NY, US

285 The Alarmin HMGB1 Is Crucial for the Acquisition of Antiviral pDC Effector Functions

Hela Saïdi[1]; Marlène Bras[1]; Pauline Formaglio[1]; Bruno Charbit[1]; Marie-Thérèse Melki[2]; Marie-Lise Gougeon[1]

On behalf of the Antiviral Immunity, Biotherapy and Vaccine Unit

[1]Institut Pasteur, Paris, France; [2]Sebia, Evry, France

286 Dysfunctional Neutrophil Responses to SIV Infection

Tiffany Hensley-McBain[1]; Laura E. Richert-Spuhler[1]; Jillian Gile[1]; Melon T. Nega[2]; Thomas H. Vanderford[2]; Jacob D. Estes[3]; Brandon F. Keele[3]; Nichole R. Klatt[1]

[1]University of Washington, Seattle, WA, US; [2]Emory University, Atlanta, GA, US; [3]Frederick National Laboratory for Cancer Research, Frederick, MD, US

TUESDAY, FEBRUARY 24, 2015

Session P-C5 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Studies of HIV-Exposed Uninfected Individuals

287 HIV-Exposed Seronegative MSM Have Increased Novel Antiviral Factors in Rectal Mucosa

Laura Romas[1]; Klara Hasselrot[2]; Kristina Broliden[2]; Carolina Herrera[3]; Garrett Westmacott[4]; Francis Plummer[4]; Terry B. Ball[4]; Adam Burgener[1]

[1]University of Manitoba, Winnipeg, Canada; [2]Karolinska Institutet, Stockholm, Sweden; [3]Imperial College London, London, United Kingdom; [4]Public Health Agency of Canada, Winnipeg, Canada

288 PBMC From Highly Exposed Seronegative Individuals Inhibit Transmitted Founder HIV

Kevin C. Olivieri[1]; Eunyoung Kim[3]; Susan Little[5]; Michael Turchin[4]; Vanessa Serrano[1]; Amna Rasheed[2]; Quy Nguyen[1]; Paul Dejesus[1]; Steven Wolinsky[3]; Sumit Chanda[1]

[1]Sanford-Burnham Medical Research Institute, San Diego, CA, US; [2]University of California Los Angeles (UCLA), Los Angeles, CA, US; [3]Northwestern University, Feinberg School of Medicine, Chicago, IL, US; [4]University of Chicago, Chicago, IL, US; [5]University of California San Diego (UCSD), San Diego, CA, US

289 HIV-1-Exposed Seronegative Persons Have Lower Mucosal Innate Immune Reactivity

Jennifer A. Fulcher[1]; Jennifer C. Hoffman[1]; Laura M. Romas[2]; Karen Tanner[1]; Terry Saunders[1]; Julie Elliott[1]; Adam D. Burgener[2]; Peter A. Anton[1]; Otto O. Yang[1]

[1]David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA, US; [2]University of Manitoba, Winnipeg, Canada

290 Increased Levels of Regulatory T-cells Correlate With Protection From HIV Infection

Laura Pattacini[1]; Jared Baeten[2]; Katherine Thomas[2]; **Tayler Fluharty**[1]; Pamela Murnane[2]; Deborah Donnell[2]; Nelly Mugo[2]; Jairam R. Lingappa[2]; Connie Celum[2]; Jennifer Lund[1]

[1]Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US; [2]University of Washington, Seattle, WA, US

Session P-C6 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Host Factors in HIV Pathogenesis

291 Estimating the Respective Contributions of Human and Viral Genetic Variation to HIV Control

István Bartha[1]; Paul J. McLaren[1]; Chanson J. Brumme[2]; Richard Harrigan[2]; Amalio Telenti[3]; Jacques Fellay[1]

[1]École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland; [2]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada; [3]J. Craig Venter Institute, La Jolla, CA, US

292 Host Gene Expression Profiles and HIV-1 Infection Outcomes

Romel D. Mackelprang[1]; Ali Filali[2]; Mark Cameron[2]; Rafick P. Sekaly[2]; Elly Katabira[3]; Allan Ronald[4]; Glenda Gray[5]; Connie Celum[1]; M Juliana McElrath[5]; Jairam R. Lingappa[1]

[1]University of Washington, Seattle, WA, US; [2]Case Western Reserve University, Cleveland, OH, US; [3]Makerere University College of Health Sciences, Kampala, Uganda; [4]University of Manitoba, Winnipeg, Canada; [5]Fred Hutchinson Cancer Research Center, Seattle, WA, US

293 Refinement of Association Signals Assessment of Residual Heritability in Host Control of HIV Viral Load

Paul J. McLaren; **Istvan Bartha**; Jacques Fellay

École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland

294 Genetic and Clinical Predictors of CD4 Recovery During Suppressive cART: WIHS

Ruth M. Greenblatt[1]; Kord Kober[1]; Peter Bacchetti[1]; Ross Boylan[1]; Kathryn Anastos[2]; Mardge Cohen[5]; Mary A. Young[3]; Deborah Gustafson[4]; Bradley Aouizerat[1]
On behalf of the WIHS

[1]University of California San Francisco, San Francisco, CA, US; [2]Montefiore Medical Center, University Hospital for Albert Einstein College of Medicine, New York, NY, US; [3]Georgetown University, Washington, DC, US; [4]State University of New York, Downstate, Brooklyn, NY, US; [5]CORE Center, Chicago, IL, US; [6]National Institutes of Health (NIH), Bethesda, MD, US

295 Host Genetic Predictors of Plasma Kynurenine/Tryptophan Among Treated HIV+ Ugandans

Sulggi A. Lee[1]; Joel Mefford[1]; Yong Huang[1]; John S. Witte[1]; Jeffrey Martin[1]; David R. Bangsberg[2]; Taisei Mushiroda[3]; Michiaki Kubo[3]; Deanna Kroetz[1]; Peter W. Hunt[1]

[1]University of California San Francisco, San Francisco, CA, US; [2]Massachusetts General Hospital and Harvard University, Boston, MA, US; [3]RIKEN Center for Genomic Medicine, Wako, Japan

296 Regulation of IL-32 Expression by a Promoter Polymorphism and MicroRNA29b in HIV-1 Patients

Carolina Scagnolari; Giulia Cacciotti; Carla Selvaggi; Noemi Giustini; Ivano Mezzaroma; Massimo Gentile; Gabriella D'Ettorre; Ombretta Turrziani; Vincenzo Vullo; Guido Antonelli

Sapienza University of Rome, Rome, Italy

297 LILRA3 Deletion Is a Genetic Risk Factor of HIV Infection

Gerrit Ahrenstorf[1]; Hui Zhi Low[1]; Katja kniesch[1]; Matthias Stoll[1]; Dirk Meyer-Olson[1]; Torsten Matthias[2]; Reinhold E. Schmidt[1]; Torsten Witte[1]

[1]Hannover Medical School, Hannover, Germany; [2]AESKU Diagnostics, Wendelsheim, Germany

298LB SIV Infection Triggers Endothelial Dysfunction and Diminished Expression of Krüppel-Like Factor 2 (KLF2) in Nonhuman Primates

Soumya Panigrahi[1]; Michael L. Freeman[1]; joseph C. mudd[4]; Nicholas Funderburg[2]; Scott Sieg[1]; David A. Zidar[1]; Mirko Paiardini[3]; Francois Villinger[3]; Mukesh K. Jain[1]; michael lederman[1]

[1]Case Western Reserve University/University Hospitals Medical Center, Cleveland, OH, US; [2]Ohio State University School of Health and Rehabilitation Sciences, Columbus, OH, US; [3]Emory University, Atlanta, GA, US; [4]Lab of Molecular Microbiology, Bethesda, MD, US

299LB A Novel Method Using ^2H_2O to Measure Collagen Turnover in HIV-Infected Individuals

Leslie R. Cockerham[1]; Claire Emson[2]; Ma Somsouk[1]; Kara Harvill[1]; Kevin Li[2]; Scott M. Turner[2]; Martin L. Decaris[2]; Marc K. Hellerstein[3]; Steven G. Deeks[1]; Hiroyu Hatano[1]

[1]University of California San Francisco, San Francisco, CA, US; [2]KineMed, Inc, Emeryville, CA, US; [3]University of California Berkeley, Berkeley, CA, US

THURSDAY, FEBRUARY 26, 2015

Session P-C7 Poster Session — Poster Hall

2:30 pm – 4:00 pm

HIV/CMV Interactions in Transmission and Pathogenesis

300 Effect of CMV and HIV Replication on T-Cell Exhaustion and Senescence During ART

Jennifer M. Dan[1]; Marta Massanella[1]; David M. Smith[1]; Eric S. Daar[2]; Michael P. Dube[3]; Richard Haubrich[1]; Sheldon Morris[1]; Sara Gianella Weibel[1]

[1]University of California San Diego, La Jolla, CA, US; [2]Harbor–University of California Los Angeles Medical Center, Torrance, CA, US; [3]University of Southern California Keck School of Medicine, Los Angeles, CA, US

301 HIV Myeloid Derived Suppressor Cells Control Cytomegalovirus Inflammation by IL-27

Ankita Garg; Stephen Spector

University of California San Diego, La Jolla, CA, US

302 Persistent Elevation of Inflammation Markers in HIV+ Persons With CMV Disease

Melissa Schechter[1]; Bruno Andrade[2]; Eleanor M. Wilson[1]; Virginia Sheikh[2]; Sonya Krishnan[2]; Margaret Caplan[1]; Gregg Roby[2]; Adam Rupert[3]; Peter Burbelo[4]; Irini Sereti[2]

[1]NIAID, Leidos Biomedical Inc., Fredrick, MD, US; [2]National Institute of Allergy and Infectious Diseases, Bethesda, MD, US; [3]NIAID, Leidos Biomedical Inc., Fredrick, MD, US; [4]National Institute of Dental and Craniofacial Research, Bethesda, MD, US

303 sCD163 Increase in HIV/CMV-Coinfected Subjects Included in ICONA Cohort

Serena Vita[3]; Miriam Lichtner[1]; Giulia Marchetti[2]; Claudia Mascia[3]; Esther Merlini[2]; Paola Cicconi[2]; Vincenzo Vullo[3]; Pier Luigi Viale[5]; Alberto Costantini[4]; Antonella d'Arminio Monforte[2]
For the Icona Foundation Study

[1]University of Rome La Sapienza, Polo Pontino, Latina, Italy; [2]San Paolo Hospital, Milano, Italy; [3]University of Rome La Sapienza, Rome, Italy; [4]University of Ancona, Ancona, Italy; [5]University of Bologna, Bologna, Italy

304 Genital CMV Shedding Predicts Syphilis Acquisition in HIV-Infected MSM on ART

Sara Gianella Weibel[1]; David M. Smith[1]; Eric Daar[2]; Michael Dube[3]; Andrea Lisco[4]; Christophe Vanpouille[5]; Richard Haubrich[1]; Sheldon Morris[1]

[1]University of California San Diego, La Jolla, CA, US; [2]Los Angeles Biomedical Research Institute at Harbor–UCLA Medical Center, Torrance, CA, US; [3]University of Southern California Keck School of Medicine, Los Angeles, CA, US; [4]National Institute of Allergy and Infectious Diseases, Bethesda, MD, US; [5]National Institute of Child Health and Human Development, Bethesda, MD, US

Session P-C8 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Aging and Immune Senescence

305 Early Start of ART Affects Late Markers of Immune Senescence

Sharon L. Karmon; Teresa H. Evering; Melissa La Mar; Martin Markowitz

Aaron Diamond AIDS Research Center, an Affiliate of the Rockefeller University, New York, NY, US

306 Chronic HIV Infection Exacerbates Cellular Aging Markers in Isolated T-Cell Subsets

Anthony Hsieh; Beheroze Sattha; Hélène Côté
CIHR Team in Cellular Aging and HIV Comorbidities in Women and Children (CARMA cohort)

University of British Columbia, Vancouver, Canada

307 Age Associated Increases in Markers of Microbial Translocation and Inflammation in HIV-1 Infection

Eileen Scully[1]; Ainsley Lockhart[1]; Lisa Huang[2]; Marisol Romero-Tejeda[1]; Mary Albrecht[4]; Chrstine D. Palmer[1]; Ronald Bosch[3]; Marcus Altfeld[1]; Daniel Kuritzkes[2]; Nina Lin[5]

[1]Ragon Institute of MGH, MIT and Harvard, Jamaica Plain, MA, US; [2]Brigham and Women's Hospital, Boston, MA, Boston, MA, US; [3]Harvard School of Public Health, Center for Biostatistics in AIDS Research, Boston, MA, US; [4]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, US; [5]Boston University School of Medicine, Boston, MA, US

Session P-C9 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Immune Pathogenesis of IRIS

308 Vitamin D, D-Dimer, IFNy and sCD14 Predict IRIS in a Prospective Multicenter Study

Laura W. Musselwhite[1]; Ann Tierney[2]; Susan Ellenberg[2]; Pablo F. Belaunzarán-Zamudio[5]; Adam Rupert[3]; Ian Sanne[4]; Michael M Lederman[6]; Juan Sierra-Madero[5]; Irini Sereti[7]

[1]Duke University, Durham, NC, US; [2]University of Pennsylvania, Philadelphia, PA, US; [3]Leidos Biomedical Inc., Reston, VA, US; [4]University of the Witwatersrand, Johannesburg, South Africa; [5]Instituto Nacional de Ciencias Medicas y Nutricion, Mexico City, Mexico; [6]Case Western Reserve University, Cleveland, OH, US; [7]National Institutes of Health (NIH), Bethesda, MD, US

309 LC-MS Analysis of Metabolites Differentiating IRIS From Non-IRIS in ACTG Study A5221

Mary A. De Groote[1]; Laura Ashton[1]; Marisa Harton[1]; Sam Bokatzien[2]; Kristofor Webb[1]; Carlos Adriano Matos de Silva[1]; Reem Al-Mubarak[1]; Sebabratra Mahapatra[1]; Diane Havlir[3]; John Belisle[1]

[1]Colorado State University, Fort Collins, CO, US; [2]National Jewish Health, Denver, CO, US; [3]University of California San Francisco, San Francisco, CA, US

310 Associations Between Plasma Cytokine and Microbial Translocation Biomarkers and IRIS

Margaret A. Fischl[2]; Linda J. Harrison[1]; Varghese George[2]; Margaret Roach[2]; Xiao-Dong Li[3]; David Asmuth[3]; Pablo Tebas[4]; Camlin Tierney[1]; Catherine Godfrey[5]; Savita Pahwa[2]

[1]Center for Biostatistics in AIDS Research, Harvard School of Public Health, Boston, MA, US; [2]University of Miami Miller School of Medicine, Miami, FL, US; [3]University of California Davis, Sacramento, CA, US; [4]University of Pennsylvania, Philadelphia, PA, US; [5]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD, US

311 Potential Role of IL-1 and IL-10 Pathways in IRIS Pathogenesis

Ainhoa Perez-Diez; **Elizabeth Richards**; Stig Jensen; Eleanor M. Wilson; Virginia Sheikh; Maura M. Manion; Bruno Andrade; Timothy Myers; Irini Sereti

National Institute of Allergy and Infectious Diseases (NIAID), Rockville, MD, US

WEDNESDAY, FEBRUARY 25, 2015

Session P-C10 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Immune Activation and HIV Pathogenesis

312 Inflammatory Biomarkers Decline but Do Not Normalize After 10 Years of cART

Kenneth A. Lichtenstein[1]; Carl Armon[2]; Vijaya Knight[1]; Rafeul Alam[1]

[1]National Jewish Health, Denver, CO, US; [2]Children's Hospital Colorado, Aurora, CO, US

313 Persistently High IL-18 and sCD14 Are Independently Associated With Clinical Failure

Ashwin Balagopal[1]; Nikhil Gupte[1]; James Hakim[2]; Mina C. Hosseinipour[3]; Nagalingeswaran Kumarasamy[4]; Andrea Cox[1]; Ian Sanne[7]; David Asmuth[5]; Thomas Campbell[6]; Amita Gupta[1]
On behalf of the ACTG

[1]Johns Hopkins University School of Medicine, Baltimore, MD, US; [2]University of Zimbabwe, College of Health Sciences, Harare, Zimbabwe; [3]University of North Carolina, Chapel Hill, NC, US; [4]Y.R.G. Care, Chennai, India; [5]University of California San Diego, San Diego, CA, US; [6]University of Colorado, Denver, CO, US; [7]ACTG, Washington, DC, US

314 Impact of Partner HIV Status on Immune Activation and Inflammation During Chronic HIV

Shameem Z. Jaumdally[1]; Pamela Gumbi[1]; Hoyam Gamieldien[1]; Anabela Picton[2]; Caroline Tiemessen[2]; Lindi Masson[1]; Lenine Liebenberg[3]; David Coetzee[1]; Anna-Lise Williamson[1]; Jo-Ann Passmore[1]

[1]University of Cape Town, Cape Town, South Africa; [2]National Institute for Communicable Diseases, National Health Laboratory Service, Johannesburg, South Africa; [3]Centre for AIDS Programme Research in South Africa, Durban, South Africa; [4]University of Cape Town, Cape Town, South Africa

315 Pretherapy Inflammation and Long-Term CD4 Response to Antiretroviral Therapy

Amit C. Achhra[1]; Andrew N. Phillips[2]; Sean Emery[1]; Rodger D. MacArthur[3]; Hansjakob Furrer[4]; Stéphane De Wit[5]; Marcelo H. Losso[6]; Matthew G. Law[1]
On behalf of the INSIGHT SMART and FIRST Study groups

[1]Kirby Institute, University of New South Wales, Sydney, Australia; [2]University College London, London, United Kingdom; [3]Wayne State University, Detroit, MI, US; [4]University Hospital Bern, Bern, Switzerland; [5]Saint-Pierre University Hospital, Brussels, Belgium; [6]Hospital J.M. Ramos Mejía, Buenos Aires, Argentina

316 Plasma Levels of sCD163 Predict All-Cause Mortality From HIV Infection

Troels Bygum Knudsen[1]; Janne Petersen[2]; Holger Jon Møller[3]; Søren Moestrup[4]; Jesper Eugen-Olsen[2]; Gitte Kronborg[1]; Thomas Benfield[1]

[1]Copenhagen University Hospitals, Hvidovre, Copenhagen, Denmark; [2]Copenhagen University Hospitals, Hvidovre, Copenhagen, Denmark; [3]Aarhus University Hospital, Aarhus, Denmark; [4]Aarhus University, Aarhus, Denmark

317 Immunologic Pathways That Predict Mortality in HIV+ Ugandans Initiating ART

Sulggi A. Lee[1]; Helen Byakwaga[2]; Yap Boum[2]; Tricia Burdo[3]; Yong Huang[1]; Jessica Haberer[5]; Annet Kembabazi[2]; David R. Bangsberg[5]; Jeffrey Martin[1]; Peter W. Hunt[1]

[1]University of California San Francisco, San Francisco, CA, US; [2]Mbarara University of Science and Technology, Mbarara, Uganda; [3]Boston College, Boston, MA, US; [4]University of California San Francisco, San Francisco, CA, US; [5]Massachusetts General Hospital and Harvard University, Boston, MA, US

318 Immune Activation Impairs Yellow Fever Vaccine Efficacy in HIV-Infected Patients

Vivian I. Avelino-Silva[1]; Karina T. Miyaji[1]; Marisol Simoes[2]; Marcos Freire[2]; Ana Sartori[1]; Peter W. Hunt[3]; Karine Milani[1]; Augusto Mathias[1]; Ana Paula Batista[1]; Esper G. Kallas[1]

[1]University of Sao Paulo Medical School, Sao Paulo, Brazil; [2]Fundaçao Oswaldo Cruz, Rio de Janeiro, Brazil; [3]University of California San Francisco, San Francisco, CA, US; [4]University of Sao Paulo Medical School, Sao Paulo, Brazil

319 Association Between sCD163 and CMV IgG in Virologically Suppressed HIV+ Patients

Aimee Hodowanec[1]; Brett Williams[1]; Barbara Hanson[1]; Britt Livak[2]; Sheila Keating[3]; Nell Lurain[1]; Oluwatoyin M. Adeyemi[4]

[1]Rush University Medical Center, Chicago, IL, US; [2]University of Chicago, Chicago, IL, US; [3]Blood Systems Research Institute/University of California San Francisco, San Francisco, CA, US; [4]Ruth M Rothstein CORE Center, Chicago, IL, US

Session P-C11 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Manipulating Immune Activation

320 The mTORC1 Inhibitors, Temsirolimus and Everolimus, Suppress HIV Patient-Derived CD4+ T-Cell Death and Activation In Vitro

Clovis S. Palmer[1]; Matias Ostrowski[4]; Jingling Zhou[1]; Linda Lam[1]; Alan Landay[2]; Anthony Jaworowski[1]; Joseph M. McCune[3]; Suzanne M. Crowe[1]

[1]Burnet Institute, Melbourne, Australia; [2]Rush University Medical Center, Chicago, IL, US; [3]University of California San Francisco, San Francisco, CA, US; [4]Instituto de Investigaciones Biomédicas en Retrovirus y SIDA, Buenos Aires, Argentina

321 Decreased Monocyte Activation With Daily Acyclovir Use in HIV-1/HSV-2 Coinfected Women

Andrew D. Redd[1]; Kevin Newell[2]; Eshan U. Patel[1]; Fred Nalugoda[3]; Paschal Ssebbowa[3]; Sarah Kaliballa[3]; Ronald H. Gray[4]; Thomas C. Quinn[1]; David Serwadda[5]; **Steven J. Reynolds**[1]

[1]National Institute of Allergy and Infectious Diseases (NIAID), Washington, DC, US; [2]Clinical Research Directorate/Clinical Monitoring Research Program, Leidos Biomedical Research, Inc., Frederick National Laboratory for Cancer Research, Frederick, MD, US; [3]Rakai Health Sciences Program, Kalisizo, Uganda; [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [5]Makerere University College of Health Sciences, Kampala, Uganda

322 Atorvastatin Reduced T-Cell Activation and Exhaustion Among Suboptimal Immune Responders: A Randomized Crossover Placebo Controlled Trial

Damalie Nakanjako

Makerere University Infectious Diseases Institute, Kampala, Uganda

323 P2X Type Purinergic Antagonists Can Block HIV-1 Infection and Associated Inflammation

Talia Swartz; Meagan O'Brien; Anthony Esposito; Nina Bhardwaj; Benjamin Chen

Icahn School of Medicine at Mount Sinai, New York, NY, US

THURSDAY, FEBRUARY 26, 2015

Session P-C12 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Pathogenesis in Lymph Nodes

324 $CD4^+$ T cell death mediated by pyroptosis in early SIV infected lymphatic tissues

Wuxun Lu[1]; Guobin Kang[1]; Fangrui Ma[1]; Yanmin Wan[2]; Yue Li[1]; Mark Lewis[3]; Qingsheng Li[1]

[1]University of Nebraska-Lincoln, Lincoln, NE, US; [2]Shanghai Public Health Clinical Center and Institutes of Biomedical Sciences, Fudan University, Shanghai, China; [3]BIOQUAL, Inc., Rockville, MD, US

325 Fibrosis in Lymphoid Tissue Is Associated With Peripheral Blood Regulatory T Cells

Julie C. Gaardbo[1]; Patricia S. Nielsen[2]; Lise Mette R. Gjerdrum[3]; Karoline Springborg[4]; Elisabeth Ralfkiær[4]; Henrik Ullum[4]; Åse Andersen[4]; **Susanne D. Poulsen**[4]
Dr. Susanne D Poulsen, sdn@dadlnet.dk

[1]University of Copenhagen, Rigshospitalet, Copenhagen, Denmark; [2]Aarhus University Hospital, Denmark, Aarhus, Denmark; [3]Bispebjerg Hospital, University Hospital of Copenhagen, Denmark, Copenhagen, Denmark; [4]Rigshospitalet, University of Copenhagen, Copenhagen, Denmark

326 Decreased T_{FR}/T_{FH} Ratio in SIV-Infected Rhesus Macaques

Ankita Chowdhury; Perla Del Río-Estrada; Steven Bosinger; Guido Silvestri

Emory University, Atlanta, GA, US

Session P-C13 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Dissecting Pathogenesis Through In Vitro Studies

327 A Dual-Tropic HIV-1 Env Interacts With CCR5 to Deplete Bystander CD4 T Cells In Vitro and In Vivo

Li-Chung Tsao[1]; Haitao Guo[2]; Jerry Jeffrey[3]; James A. Hoxie[4]; Lishan Su[2]

[1]University of North Carolina, Carrboro, NC, US; [2]University of North Carolina, Chapel Hill, NC, US; [3]GSK, Chapel Hill, NC, US; [4]University of Pennsylvania, Philadelphia, PA, US

328 Investigation of the Association of Gag-Protease Dependent Replication Capacities With Clinical Outcomes of HIV-1 Infection

Keiko Sakai[1]; Takayuki Chikata[1]; Hiroyuki Gatanaga[2]; Shinichi Oka[2]; Masafumi Takiguchi[1]

[1]Kumamoto University, Kumamoto-shi, Japan; [2]National Center for Global Health and Medicine, Tokyo, Japan

329 Association of Bacteria-Induced IL-23 and Th17 Frequencies in HIV-1^+ Individuals

Jennifer Manuzak[1]; Sonia Amraoui[1]; Nipa Decroix[2]; Pierre Loulergue[2]; Odile Launay[2]; Marco Iannetta[1]; Jean-Baptiste Guillerme[1]; Lene Vimeux[1]; Anne Hosmalin[1]

[1]Inserm U1016, Institut Cochin, Paris, France; [2]Centre d'Investigation Clinique CIC 1417, Inserm-AP-HP, Hôpital Cochin, Paris, France

330 Effect of Methamphetamine Use on T-Cell Proliferation In Vivo and Ex Vivo

Marta Massanella[4]; Sara Gianella[4]; Jennifer M. Dan[1]; Eric Daar[2]; Michael P. Dube[3]; Richard H. Haubrich[4]; Douglas D. Richman[4]; Davey M. Smith[4]; Sheldon Morris[4]; Rachel D. Schrier[4]

[1]La Jolla Institute of Allergy and Immunology, La Jolla, CA, US; [2]Los Angeles Biomedical Research Institute at Harbor–University of California Los Angeles Medical Center, Torrance, CA, US; [3]University of Southern California Keck School of Medicine, Los Angeles, CA, US; [4]University of California San Diego, La Jolla, CA, US

Session P-C14 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Dissecting Pathogenesis Through In Vivo Studies

331 A Random Forest Approach to Define Immunological Thresholds for CD4 Recovery in HIV-Treated Individuals

Josué Pérez-Santiago[1]; **Marta Massanella**[1]; Dan Ouchi[2]; Elisabet Gómez[2]; Cecilia Cabrera[2]; Bonaventura Clotet[3]; Eugenia Negredo[3]; Julià Blanco[2]

[1]University of California San Diego, La Jolla, CA, US; [2]IrsiCaixa Institute for AIDS Research, Badalona, Spain; [3]Lluita Contra la Sida Foundation, Germans Trias i Pujol University Hospital, Badalona, Spain

332 Disease Progression in HIV Controllers; Uptake and Outcome of Antiretroviral Therapy

Jane R. Deayton[1]; Katherine C. Groves[2]; David F. Bibby[2]; Duncan A. Clark[2]; Iain Reeves[3]; Jane Anderson[3]; Chloe M. Orkin[4]; Eithne O'Sullivan[1]; Áine McKnight[1]

[1]Barts and the London, Que, London, United Kingdom; [2]Barts Health NHS Trust, London, United Kingdom; [3]Homerton University Hospital NHS Foundation Trust, London, United Kingdom; [4]Barts Health NHS Trust, London, United Kingdom

333 Immunological and Virological Progression in HIV Controllers

Nicolas Noel[1]; Nathalie Lerolle[1]; Camille Lecuroux[2]; Cécile Goujard[1]; Alain Venet[2]; Asier Sáez-Cirión[3]; Véronique Avettand-Fenoel[4]; Laurence Meyer[5]; Faroudy Boufassa[5]; Olivier Lambotte[1]
ANRS CO21/CODEX Study Group

[1]APHP, Service de Médecine Interne et Immunologie Clinique, Hôpital Bicêtre, Le Kremlin-Bicêtre, France, Le Kremlin Bicêtre, France; [2]Inserm U1012, Régulation de la Réponse Immune, Infection VIH1 et Autoimmunité, Le Kremlin Bicêtre, France; [3]Institut Pasteur, Unité de Régulation des Infections Rétrovirales, Paris, France; [4]APHP, Service de Virologie, Hôpital Necker – Enfants Malades, Paris, France; [5]Inserm U1018, Centre de Recherche en Epidémiologie et Santé des Populations, Université Paris Sud, Le Kremlin-Bicêtre, France

334 HIV Replication History Is Associated With Plasma IL-7 Levels in Aviremic Youths

Daniel Scott-Algara[1]; Jerome Lechenadec[2]; Josiane Warszawski[2]; Thomas Montange[1]; Jean-Paul Viard[3]; Catherine Dollfus[3]; Véronique Avettand-Fenoel[4]; Christine Rouzioux[4]; Stéphane Blanche[3]; **Florence Buseyne**[1]

[1]Institut Pasteur, Paris, France; [2]Inserm, Le Kremlin-Bicêtre, France; [3]AP-HP, Paris, France; [4]Université Paris Descartes, Paris, France

335 Enhanced Immune Reconstitution With Initiation of ART at HIV-1 Seroconversion (PHI)

Sabine I. Kinloch[1]; Colette Smith[1]; Kwong Tsz-Shan[2]; Jayne Ellis[2]; Margaret Johnson[2]

[1]University College London, London, United Kingdom; [2]Royal Free London NHS Foundation Trust, London, United Kingdom

336 cART-Driven Recovery of Immune Function Preferentially Targeting CXCR4-Tropic HIV-1

Joëlle Bader[1]; Martin Däumer[2]; Jürg Böni[4]; Meri Gorgievski[3]; Thomas Klimkait[1]
The Swiss HIV Cohort Study

[1]University of Basel, Basel, Switzerland; [2]Institute for Immunogenetics, Kaiserslautern, Germany; [3]University of Berne, Berne, Switzerland; [4]Swiss National Center for Retroviruses, Zürich, Switzerland

337 Repeated injections of r-hIL-7 in HIV Patients receiving ART in INSPIRE 2 & 3 trials

Rodolphe Thiebaut[1]; Ana Jarne[1]; Jean-Pierre Routy[2]; Irini Sereti[3]; Margaret A. Fischl[4]; Prudence Ive[5]; Roberto Speck[6]; Giuseppe Tambussi[7]; Yves Lévy[8]; Michael M Lederman[9]
on behalf of Inspire 2 and Inspire 3 study groups

[1]Bordeaux University, Bordeaux, France; [2]McGill University, Montreal, Canada; [3]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD, US; [4]University of Miami, Miami, FL, US; [5]Wits Health consortium, Johannesburg, South Africa; [6]University Hospital Zurich, Zurich, Switzerland; [7]San Raffaele Scientific Institute, Milano, Italy; [8]INSERM, Paris, France; [9]Case Western Reserve University, Cleveland, OH, US

338 CRF19_cpx Is an Evolutionary Fit HIV-1 Variant Exclusively Associated With Rapid Progression to AIDS in Cuba

Vivian Kouri[2]; Ricardo Khouri[1]; Yoan Alemán[2]; Yeissel Abrahantes[2]; Nico Pfeifer[3]; Andrea-Clemencia Pineda-Peña[4]; Jorge Pérez[2]; Lissette Pérez[2]; Kristel Van Laethem[4]; **Anne-Mieke Vandamme**[4]

[1]Fundação Oswaldo Cruz, Salvador, Brazil; [2]Instituto Pedro Kouri, Havana, Cuba; [3]Max Planck Institute for Informatics, Saarbrucken, Germany; [4]Katholieke Universiteit Leuven, Leuven, Belgium

TUESDAY, FEBRUARY 24, 2015

Session P-E1 Poster Session — Poster Hall

2:30 pm – 4:00 pm

The Effect of HIV Infection on B Cells

339 Acute HIV-1 Infection Is Associated With Rapid Changes in B-Cell Subsets and Levels of CXCL13

Jenniffer K. Maroa[1]; Anne-Sophie Dugust[2]; Zelda Euler[2]; Yathisha Ramlakhan[1]; Krista Dong[3]; Bruce Walker[2]; Thumbi Ndung'u[4]; Galit Alter[2]

[1]University of KwaZulu-Natal, Durban, South Africa; [2]Ragon Institute of MIT, MGH and Harvard, Boston, MA, US; [3]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [4]HIV Pathogenesis Programme, Durban, South Africa

340 Bone Marrow Plasma Cells Dictate Serum HIV-Specific Antibodies in Chronic Viremia

Jairo Mauricio Montezuma-Rusca[1]; **Olivia R. Fankuchen**[1]; Lela Kardava[1]; Clarisa M. Buckner[1]; Aaron Louie[1]; Yuxing Li[2]; Tae Wook Chun[1]; Katherine R. Calvo[3]; Susan Moir[1]; Anthony S. Fauci[1]

[1]NIAID/NIH, Bethesda, MD, US; [2]University of Maryland, Rockville, MD, US; [3]NIH Clinical Center, Bethesda, MD, US

341 Reduced Expression of Blimp-1 on Memory B Cells in Patients with HIV-1 Infection

Claudia Beisel; Ilona Toth; Jan van Lunzen; Julian Schulze zur Wiesch

University Hospital Hamburg-Eppendorf, Hamburg, Germany

342 Similar or Higher Memory Responses to Influenza Vaccination in Aviremic HIV-infected Patients on Antiretroviral Therapy

Zhenwu Luo; Lisa Martin; J. Michael Kilby; **Wei Jiang**

Medical University of South Carolina, Charleston, SC, US

Session P-E2 Poster Session — Poster Hall

2:30 pm – 4:00 pm

The Envelope/Antibody Dynamic

343 Estimating and Visualizing HIV-1 Susceptibility to Broadly Neutralizing Antibodies

Anna Feldmann; Nico Pfeifer

Max Planck Institute for Informatics, Saarbrücken, Germany

344 Sequential SHIV-Env Clones With Neutralization Sensitivity for Breadth Development

Manxue Jia; Cecilia Cheng-Mayer; Xueling Wu

Aaron Diamond AIDS Research Center, New York, NY, US

345 V1V2 Neutralizing Epitopes Are Conserved Within Divergent Groups of HIV-1

Marion Morgand[1]; Mélanie Bouvin-Pley[1]; Craig S Pace[2]; David Ho[2]; Pascal Poignard[3]; Marie Pancera[4]; Jean-Christophe Plantier[5]; Francois Simon[6]; Martine Braibant[1]; Francis Barin[7]

[1]Université de Tours, Inserm U966, Tours, France; [2]Aaron Diamond AIDS Research Center, The Rockefeller University, New York, NY, US; [3]Department of Immunology and Microbial Science, The Scripps Research Institute, La Jolla, CA, US; [4]Vaccine Research Center, NIAID, NIH, Bethesda, WA, US; [5]Université de Rouen, CHU Charles Nicolle, Rouen, France; [6]Laboratoire de Virologie, Hôpital St Louis, Paris, France; [7]Université de Tours, Inserm U966, Laboratoire de Bactériologie-Virologie, CNR du VIH, CHU Bretonneau, Tours, France

346 Improving Neutralization Potency and Breadth by Combining Broadly Reactive HIV-1 Antibodies Targeting Major Neutralization Epitopes

Rui Kong[1]; Mark Louder[1]; Kshitij Wagh[2]; Robert Bailer[1]; Kelli Greene[3]; Hongmei Gao[3]; Michel Nussenzweig[4]; Bette Korber[2]; David Montefiori[3]; John Mascola[1]

[1]Vaccine Research Center, NIAID, NIH, Bethesda, MD, US; [2]Los Alamos National Laboratory, Los Alamos, NM, US; [3]Duke University Medical Center, Durham, NC, US; [4]The Rockefeller University, New York, NY, US

347 Improved Antibody Cross-Neutralizing Activity in HIV-1 Dual-Infected LTNP Patients

Maria Pernas[1]; Concepción Casado[1]; Victor Sanchez-Merino[2]; Alberto Sanchez-Merino[2]; Isabel Olivares[1]; eloisa Yuste[2]; Cecilio Lopez-Galíndez[1]

[1]Instituto de Salud Carlos III, Majadahonda, Spain; [2]Institut d'Investigacions Biomediquès, Barcelona, Spain

348 Characterization of CD4 Independent HIV-1 Envelope as Potential Immunogens

Lifei Yang[1]; Bradley Cleveland[1]; Andrea P. Jordan[2]; Patricia Polacino[1]; James A. Hoxie[2]; Shiu-Lok Hu[1]

[1]University of Washington, Seattle, WA, US; [2]University of Pennsylvania, Philadelphia, PA, US

349 Phenotypic Neutralization Sieve Analysis of an SIV Nonhuman Primate Vaccine Challenge Study

Fang-Hua Lee[1]; Brandon F. Keele[3]; Robert Doms[1]; George M. Shaw[1]; Mario Roederer[2]; **Katharine J. Bar**[1]

[1]University of Pennsylvania, Philadelphia, PA, US; [2]Vaccine Research Center, NIAID, NIH, Bethesda, MD, US; [3]National Cancer Institute, Frederick, MD, US

350 AvFc, a Novel Fc Fusion Protein Targeting Env High-Mannose Glycans

Nobuyuki Matoba; Adam Husk; J. Calvin Kouokam; Krystal Hamorsky; Tiffany Grooms-Williams; Garima Mahajan

University of Louisville James Graham Brown Cancer Center, Owensboro, KY, US

351 DARPins as Entry Inhibitor Alternative to HIV-1 Broadly Neutralizing Antibodies

Emanuel Stiegeler; Nikolas Friedrich; Thomas Reinberg; Mylène Morin; Yufan Wu; Jonas V. Schaefer; Peter Rusert; John Robinson; Andreas Plückthun; Alexandra Trkola

University of Zurich, Zurich, Switzerland

WEDNESDAY, FEBRUARY 25, 2015

Session P-E3 Poster Session — Poster Hall

2:30 pm – 4:00 pm

New Approaches to Immunostimulation

352 Use of Pre-ART-Adjusted Endpoints in the Analysis of an HIV Therapeutic Vaccine Trial

Yunda Huang[1]; Lily Zhang[1]; Darren Jolliffe[3]; Arnt-Ove Hovden[4]; Mats Okvist[4]; Pantaleo Giuseppe[2]; Maja A. Sommerfelt[4]

[1]Fred Hutchinson Cancer Research Center, Seattle, WA, US; [2]Lausanne University Hospital, Lausanne, Switzerland; [3]S-cubed Biometrics Ltd, Oxfordshire, United Kingdom; [4]Bionor Pharma ASA, Oslo, Norway

353 Decreased HIV-Specific T-Regulatory Responses Mark Effective Vaccine-Induced Immunity

Vedran Brezar[1]; Nicolas Ruffin[1]; Laura Richert[2]; Mathieu Surenaud[1]; Christine Lacabaratz[1]; Karolina Palucka[3]; Rodolphe Thiebaut[2]; Jacques Banchereau[1]; Yves Lévy[1]; Nabila Seddiki[1]

[1]Inserm U955 (Eq16)-UPEC-VRI, Créteil, France; [2]Univ Bordeaux-ISPED-Inserm U897-VRI, Bordeaux, France; [3]Ralph M. Steinman Center for Cancer Vaccines–Baylor Institute for Immunology Research, Dallas, TX, US

354 Viral Reservoir Dynamics After Therapeutic Vaccination and cART Interruption

Cristina Andres[1]; Carmen Alvarez-Fernandez[1]; Nuria Climent[1]; Teresa Gallart[1]; Montserrat Plana[1]; Agathe Leon[1]; Nicolas Chomont[2]; Jose M. Gatell[1]; **Felipe Garcia**[1]; Sonsoles Sanchez-Palomino[1]

[1]Hospital Clinic, Barcelona, Spain; [2]Vaccine and Gene Therapy Institute, Port St Lucie, FL, US

355 HIV-1 Envelope Epitope Recognition Is Influenced by Immunoglobulin D_H Gene Segment Repertoire

Yuge Wang[2]; Aaron Sanchez-Silva[2]; Barton Haynes[1]; Harry Schroeder[2]

[1]Duke University, Durham, NC, US; [2]University of Alabama at Birmingham, Birmingham, AL, US; [3]University of Alabama at Birmingham, Birmingham, AL, US

356 Human Rhinovirus Displaying HIV-1 4E10 Epitope Elicits Broad Neutralization in hICAM-1 Tg Mice

Guohua Yi[1]; Xiongying Tu[2]; Preeti Bharaj[1]; Premlata Shankar[1]; Manjunath Swamy[1]

[1]Texas Tech University Health Sciences Center, El Paso, TX, US; [2]University of Minnesota, St Paul, MN, US

357 WITHDRAWN

358 A Superagonist Antibody to Human Interleukin-21 Increases HIV-Specific T-Cell Function

Yew Ann Leong[1]; Yanfang Cui[1]; Zhian Chen[1]; Fiona Wightman[1]; Pellegrini Marc[2]; Jamie Rossjohn[1]; Sharon R. Lewin[3]; Alan Landay[4]; Charles Mackay[1]; Di Yu[1]

[1]Monash University/Alfred Hospital, Melbourne, Australia; [2]Walter and Eliza Hall Institution, Melbourne, Australia; [3]University of Melbourne, Melbourne, Australia; [4]Rush University Medical Center, Chicago, IL, US; [5]Monash University/Alfred Hospital, Melbourne, Australia

THURSDAY, FEBRUARY 26, 2015

Session P-E4 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Cellular Immune Response to HIV

359 Evolution of HIV-Specific CD8+ T-Cell Responses in Hyperacute HIV Infection

Zaza M. Ndhlovu[1]; Nikoshia Mewalal[1]; Philomena Kamya[1]; Thandeka Nkosi[1]; Karyn Pretorius[1]; Nasreen Ismail[1]; Amber Moodley[2]; Krista Dong[2]; Thumbi Ndung'u[1]; Bruce Walker[2]

[1]University of KwaZulu-Natal, Durban, South Africa; [2]Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, US

360 Nonclassical Regulatory HIV-1–Specific CD8 T Cells in HIV-1 Disease Progression

Selena Vigano[2]; Chun Li[2]; Jordi J. Negron[2]; Bruce D. Walker[2]; Mathias Lichterfeld[1]; Xu G. Yu[2]

[1]Massachusetts General Hospital, Boston, MA, US; [2]The Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, US

361 Nef Plays a Role in the Resistance of SIV-Infected Macrophages to $CD8^+$ T-Cell Suppression

Jennifer N. Rainho; Mauricio A. Martins; Francesc Cunyat; David I. Watkins; Mario Stevenson

University of Miami, Miami, FL, US

362 Defining Efficacious HIV-Specific CTL Responses Using Saporin-Conjugated Tetramers

Ellen M. Leitman[1]; Stuart Sims[2]; Rebecca P. Payne[1]; Fabian Chen[3]; Lynn Riddell[4]; Soren Buus[5]; Steven Deeks[6]; Bruce Walker[7]; Philippa C. Matthews[1]; Philip J. Goulder[1]

[1]University of Oxford, Oxford, United Kingdom; [2]ETH Zurich, Basel, Switzerland; [3]Royal Berkshire Hospital, Reading, United Kingdom; [4]Northamptonshire Healthcare NHS Trust, Northampton, United Kingdom; [5]University of Copenhagen, Copenhagen, Denmark; [6]University of California San Francisco, San Francisco, CA, US; [7]Ragon Institute of MGH, MIT and Harvard, Charlestown, MA, US

363 Linking Pig-Tailed Macaque Major Histocompatibility Complex Class I Haplotypes and Cytotoxic T Lymphocyte Escape Mutations in SIV Infection

Shayarana Gooneratne[1]; Hamid Alinejad-Rokny[2]; Diako Ebrahimi Mohammadi[2]; Patrick Bohn[3]; Roger Wiseman[3]; David O'Connor[3]; Miles Davenport[2]; Stephen Kent[1]

[1]University of Melbourne, Melbourne, Australia; [2]University of New South Wales, Kensington, Australia; [3]University of Wisconsin Madison, Madison, WI, US

364 HLA Class-II–Associated HIV Polymorphisms Predict Escape From CD4 T-Cell Responses

Nathaniel B. Erdmann[1]; Victor Du[1]; Jonathan M. Carlson[2]; John Sidney[3]; Ling Yue[4]; Susan Allen[4]; Eric Hunter[4]; Sonya L. Heath[1]; Anju Bansal[1]; Paul A. Goepfert[1]

[1]University of Alabama at Birmingham, Birmingham, AL, US; [2]Microsoft Research, Los Angeles, CA, US; [3]La Jolla Institute of Allergy and Immunology, La Jolla, CA, US; [4]Emory University, Atlanta, GA, US

365 Rapid Construction of HIV-1-Specific T Cell Receptor Gene Therapy Lentiviral Vectors

Christian Hofmann; Christian-Raul Aguilera-Sandoval; Arumugam Balamurugan; Priya Patel; Brian Diep; Edward Martin; Sangeun Park; Diana Y. Chen; Hwee Ng; Otto O. Yang

University of California Los Angeles, Los Angeles, CA, US

366 The Role of Exosomes in Semen in Suppressing Natural and Vaccine-Induced Immunity

Lucia Vojtech; Sean Hughes; Claire Levy; Florian Hladik

University of Washington, Seattle, WA, US

367 IFN-alpha Stimulated NK Lysis of HIV-Infected $CD4^+$ T Cells Requires NKp46 and NKG2D

Costin Tomescu[1]; Domenico Mavilio[2]; Luis J. Montaner[1]

[1]The Wistar Institute, Philadelphia, PA, US; [2]Humanitas Clinical and Research Center, Milan, Italy

TUESDAY, FEBRUARY 24, 2015

Session P-F1 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Immune-Based Strategies in Latency

368 Stimulation of Broad CTL Response Is Required to Clear Latent HIV-1 in Humanized Mice

Liang Shan[1]; Kai Deng[2]; Richard Flavell[1]; Robert F. Siliciano[2]

[1]Yale University, New Haven, CT, US; [2]Johns Hopkins University School of Medicine, Baltimore, MD, US

369 *In vivo* effects of Panobinostat and Romidepsin on HIV-1-specific CD8 T Cell Immunity

Rikke Olesen[1]; Thomas A. Rasmussen[1]; Mathias Lichterfeld[2]; Mette E. Graversen[1]; Steffen Leth[1]; Lars Østergaard[1]; Ole S. Søgaard[1]; Martin Tolstrup[1]

[1]Aarhus University Hospital, Aarhus, Denmark; [2]Ragon Institute of MIT, MGH and Harvard, Boston, MA, US

370 Vaccine Induced Follicular CD8 T Cells Enhance Control of Pathogenic SIV Infection

Geetha H. Mylvaganam; Daniel Rios; Gregory Tharp; Steven Bosinger; Vijayakumar Velu; Rama R. Amara

Emory University, Atlanta, GA, US

371 Blockade of PD-L1 Does Not Reverse HIV Latency in CD4+ T Cells Ex Vivo

Elizabeth Fyne[1]; Shalyn Campellone[2]; Huilin Qi[2]; Amy Sheaffer[2]; Stephen Mason[2]; John W. Mellors[1]

[1]University of Pittsburgh, Pittsburgh, PA, US; [2]Bristol-Myers Squibb Co., Wallingford, CT, US

372 Impact of HIV Latency Reversing Agents on Natural Killer Cells

Carolina Garrido; Julia Sung; Swati Gupta; Katherine Sholtis; Nancie Archin; David Margolis Medicine, University of North Carolina

University of North Carolina, Chapel Hill, NC, US

THURSDAY, FEBRUARY 26, 2015

Session P-F2 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Viral Reservoir Dynamics During ART

373 The Earlier cART Is Initiated During PHI, the More Intracellular HIV-DNA Decreases

Moussa Laanani[2]; Jade Ghosn[1]; Asma Essat[2]; Adeline Mélard[3]; Rémonie Seng[2]; Emmanuel Mortier[4]; Cécile Goujard[2]; Laurence Meyer[2]; Christine Rouzioux[3]
On behalf of the ANRS PRIMO Cohort Study Group

[1]APHP, Hôtel Dieu University Hospital, Paris, France; [2]APHP, Bicêtre Hospital, Le Kremlin-Bicêtre, France; [3]APHP, Necker Hospital, Paris, France; [4]APHP, Louis Mourier Hospital, Colombes, France

374 Decay Rate and HIV-1 DNA Reservoir Size Following Early Infant Antiretroviral Therapy

Priyanka Uprety[1]; Kaitlin Rainwater-Lovett[2]; Ellen G. Chadwick[3]; Edmund Capparelli[4]; Carrie Ziemniak[2]; Katherine Luzuriaga[5]; Larry Moulton[1]; Deborah Persaud[2]
International Maternal Pediatric Adolescent AIDS Clinical Trial Network (IMPAACT) P1030 trial group

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [2]Johns Hopkins University School of Medicine, Baltimore, MD, US; [3]Northwestern University, Feinberg School of Medicine, Chicago, IL, US; [4]University of California San Diego, San Diego, CA, US; [5]University of Massachusetts Medical School, Boston, MA, US

375 Detectable CMV in PBMC Is Associated With Slower HIV DNA Decay During Suppressive ART

Sara Gianella Weibel; Christy Anderson; Susanna R. Var; Michelli Faria de Oliveira; Marta Massanella; Susan J. Little; Douglas D. Richman; Matt Strain; Josue Pérez-Santiago; David M. Smith

University of California San Diego, La Jolla, CA, US

376 Stable Total HIV-1 DNA Levels Prior and Post ART Interruption in Chronic HIV

Emmanouil Papasavvas[1]; Matthew Strain[2]; Steven Lada[2]; Jocelin Joseph[1]; Livio Azzoni[1]; Karam Mounzer[3]; Jay R. Kostman[4]; Douglas D. Richman[2]; Luis J. Montaner[1]

[1]The Wistar Institute, Philadelphia, PA, US; [2]VA San Diego Healthcare System and the University of California, San Diego, CA, US; [3]Jonathan Lax Immune Disorders Treatment Center, Philadelphia Field Initiating Group for HIV-1 Trials, Philadelphia, PA, US; [4]Presbyterian Hospital–University of Pennsylvania Hospital, Philadelphia, PA, US

377 Aviremia 10-Year Post-ART Discontinuation Initiated at Seroconversion

Sabine I. Kinloch[1]; Lucy Dorrell[2]; Hongbing Yang[2]; Linos Vandekerckhove[3]; Ward de Spiegelaere[3]; Eva Malatinkova[3]; Sabine Yerly[4]; Daniel Webster[5]; Margaret Johnson[5]

[1]University College London, London, United Kingdom; [2]University of Oxford, Oxford, United Kingdom; [3]Universitair Ziehenhuis Gent, Gent, Belgium; [4]Geneva University Hospital, Geneva, Switzerland; [5]Royal Free London NHS Foundation Trust, London, United Kingdom

378 Identifying HIV Variants that Rebound after Treatment Interruption

Mary F. Kearney[2]; Wei Shao[3]; Rajesh T. Gandhi[4]; Brandon F. Keele[3]; **Jonathan Z. Li**[1]

[1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, US; [2]National Cancer Institute (NCI), Frederick, MD, US; [3]Frederick National Laboratories for Cancer Research, Frederick, MD, US; [4]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US

379 Characterizing the Active HIV Reservoir on ART: Cell-Associated HIV RNA and Viremia

Feiyu Hong; Elizabeth Fyne; Anthony R. Cillo; Margaret A. Bedison; Dianna Koontz; John W. Mellors

University of Pittsburgh, Pittsburgh, PA, US

380 Liver Macrophages and HIV-1 Persistence

Abraham J. Kandathil; Christine M. Durand; Jeffrey Quinn; Andrew Cameron; David L. Thomas; Ashwin Balagopal

Johns Hopkins School of Medicine, Baltimore, MD, US

381 Large-Scale Analysis of HIV-1 Integration Sites in Untreated and Treated Patients

Stephanie Laufs[1]; **Diana Schenkwein**[1]; Neeltje Kootstra[2]; Frank A. Giordano[5]; Christoph Stephan[3]; Hans-Georg Kraeusslich[4]; Winfried Kern[6]; Susanne Usadel[6]; Manfred Schmidt[1]; Christof von Kalle[1]

[1]National Center for Tumor Diseases; German Cancer Research Center, Heidelberg, Germany; [2]Sanquin Research, Landsteiner Laboratory, and Center for Infectious Diseases and Immunity Amsterdam, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands; [3]University Hospital Frankfurt, Frankfurt, Germany; [4]Department of Infectious Diseases, Virology, University Hospital Heidelberg, Heidelberg, Germany; [5]Heidelberg University, Heidelberg, Germany; [6]Division of Infectious Diseases, Department of Medicine, Albert-Ludwigs-University Center for Infectious Diseases & Travel Medicine, and IFB-Center for Chronic Immunodeficiency, University Hospital, Freiburg, Germany

382 Identical Sequence Expansions Are Predominantly Found in Effector Memory T Cells

Susanne von Stockenstrom[1]; Eunok Lee[2]; Lina Odevall[1]; Elizabeth Sinclair[3]; Hiroyu Hatano[3]; Peter Bacchetti[4]; Peter W. Hunt[3]; Steven G. Deeks[3]; Frederick M. Hecht[3]; Sarah E. Palmer[2]

[1]Karolinska Institutet, Stockholm, Sweden; [2]Westmead Millenium Institute and University of Sydney, Sydney, Australia; [3]Department of Medicine, University of California San Francisco, San Francisco, CA, US; [4]Department of Epidemiology and Biostatistics, University of California San Francisco, San Francisco, CA, US

383 Long-Term Effect of Temporary ART During Primary HIV Infection on the Viral Reservoir

Alexander Pasternak[1]; Jan Prins[2]; Ben Berkhout[1]

[1]Academic Medical Center University of Amsterdam, Amsterdam, Netherlands; [2]Academic Medical Center University of Amsterdam, Amsterdam, Netherlands

Session P-F3 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Cellular Factors of Latency

384 Minor Contribution of Host-HIV Readthrough Transcripts to the Level of HIV-1 *gag* RNA

Alexander Pasternak[1]; Una O'Doherty[2]; Ben Berkhout[1]

[1]Academic Medical Center University of Amsterdam, Amsterdam, Netherlands; [2]University of Pennsylvania, Philadelphia, PA, US

385 MicroRNA-155 Reinforces HIV Latency by Downregulating the TRIM32 Viral Activator

Debbie S. Ruelas[2]; Jonathan Chan[2]; Eugene Oh[1]; Amy Heidersbach[2]; Andrew Hebbeler[2]; Leonard Chavez[2]; Eric Verdin[2]; Warner C. Greene[2]

[1]University of California San Francisco (UCSF), San Francisco, CA, US; [2]University of California Berkeley, Berkeley, CA, US

386 Select Host Restriction Factors Are Associated With HIV Persistence During Therapy

Mohamed Abdel-Mohsen[1]; Leonard Chavez[1]; Charlene Wang[1]; Matt Strain[2]; Xutao Deng[1]; Christopher D. Pilcher[3]; Teri Liegler[3]; Douglas D. Richman[2]; Steven Deeks[3]; Satish Pillai[1]

[1]Blood Systems Research Institute, San Francisco, CA, US; [2]University of California San Diego, La Jolla, CA, US; [3]University of California San Francisco, San Francisco, CA, US

387 Selectively Eliminating HIV Latently Infected Cells Without Viral Reactivation

Grant R. Campbell; Rachel S. Bruckman; Yen-Lin Chu; Stephen A. Spector

University of California San Diego, La Jolla, CA, US

388 PD1 Identifies Latently HIV-Infected Nonproliferating and Proliferating CD4+ T Cells

Renee M. van der Sluis[1]; Nitasha A. Kumar[1]; Vanessa A. Evans[1]; Rafick P. Sekaly[2]; Remi Fromentin[2]; Nicolas Chomont[2]; Paul U. Cameron[1]; Sharon R. Lewin[1]

[1]Doherty Institute, Melbourne University, Melbourne, Australia; [2]VGTI-Vaccine and Gene Therapy Institute Florida, Port St. Lucie, FL, US

389LB 2B4+PD1+ Naïve and Memory CD4+ T Cells Are Associated With Residual Viremia on ART

Cynitha Klamar; Feiyu Hong; John Bui; Anthony R. Cillo; Arcadio Agudelo-Hernandez; Deborah A. McMahon; Charles R. Rinaldo; John W. Mellors; **Bernard J. Macatangay**

University of Pittsburgh, Pittsburgh, PA, US

390 Nascent LTR-Driven Transcription Can Lead to Translation of HIV Proteins in Resting CD4+ T Cells

Laura DeMaster[1]; Alexander Pasternak[2]; Una O'Doherty[1]

[1]University of Pennsylvania, Philadelphia, PA, US; [2]Academic Medical Center University of Amsterdam, Amsterdam, Netherlands

WEDNESDAY, FEBRUARY 25, 2015

Session P-F4 Poster Session **Poster Hall**

2:30 pm – 4:00 pm

Dynamics of Latency and Reactivation

391 Influenza Vaccination Increases HIV-1 Transcription During Antiretroviral Therapy

Christina C. Yek[1]; Sara Gianella[1]; Montserrat Plana[2]; Pedro Castro[2]; Felipe Garcia[2]; Marta Massanella[1]; David M. Smith[1]

[1]University of California San Diego, San Diego, CA, US; [2]University of Barcelona, Barcelona, Spain

392 Defective HIV-1 Proviruses Can Be Transcribed Upon Activation

Ya-Chi Ho; Ross Pollack; Patrick Yong; Robert F. Siliciano

Johns Hopkins University School of Medicine, Baltimore, MD, US

393 Kinetics of HIV-1 Gene Expression Following Reactivation in a Primary Cell Model of Latency

Victoria Walker-Sperling; Joel Blankson

Johns Hopkins University School of Medicine, Baltimore, MD, US

394 Variable HIV Replication Competency Following Latency Disruption in CD4+ T Cells

Jason M. Hataye; Joseph Casazza; David Ambrozak; Eli Boritz; Takuya Yamamoto; Daniel Douek; Richard A. Koup

National Institute of Allergy and Infectious Diseases, Bethesda, MD, US

395 Latent HIV-1 Reactivation and Lysosomal Destabilization Synergize to Host Cell Death

Metodi Stankov[1]; Christina Suhr[1]; Hazel Lin[1]; Diana Panayotova-Dimitrova[2]; Christine Goffinet[1]; Georg Behrens[1]

[1]Hannover Medical School, Hannover, Germany; [2]Mannheim Clinic of University of Heidelberg, Mannheim, Germany

396 Noninduced Proviral Genome Characterization in Perinatal HIV Infection

Kaitlin Rainwater-Lovett[1]; Carrie Ziemniak[1]; Douglas Watson[2]; Katherine Luzuriaga[3]; Priyanka Uprety[4]; Yahui Chen[1]; Ya-Chi Ho[1]; Deborah Persaud[1]

[1]Johns Hopkins University School of Medicine, Baltimore, MD, US; [2]University of Maryland, Baltimore, MD, US; [3]University of Massachusetts Medical School, Worcester, MA, US; [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [5]Johns Hopkins University School of Medicine, Baltimore, MD, US

397 Multiple Rounds of T-Cell Activation Induce Additional HIV-1 From the Latent Reservoir

Nina N. Hosmane; Adam A. Capoferri; Robert F. Siliciano

Johns Hopkins University School of Medicine, Baltimore, MD, US

398 The Inducible HIV-1 Reservoir Predicted by Combinations of pre- and on-ART Parameters

Anthony R. Cillo; Michele Sobolowski; Elizabeth Fyne; Dianna Koontz; Feiyu Hong; John W. Mellors

University of Pittsburgh, Pittsburgh, PA, US

399 Effects of Antineoplastic Chemotherapy on Dynamics of HIV Population Genetics In Vivo

Sarah A. Watters[1]; Wei Shao[1]; Kieron Dunleavy[3]; Margaret Shovlin[3]; Mark N. Polizzotto[3]; Thomas S. Uldrick[3]; Robert Yarchoan[3]; Wyndham Wilson[3]; Frank Maldarelli[1]

[1]National Cancer Institute (NCI), Frederick, MD, US; [2]National Cancer Institute (NCI), Frederick, MD, US; [3]National Cancer Institute (NCI), Bethesda, MD, US; [4]National Cancer Institute (NCI), Bethesda, MD, US; [5]National Cancer Institute (NCI), Bethesda, MD, US; [6]National Cancer Institute (NCI), Bethesda, MD, US

Session P-F5 Poster Session **Poster Hall**

2:30 pm – 4:00 pm

Gene Editing

400 Targeted Disruption of Essential HIV-1 Proviral Genes by Rare-Cutting Endonucleases

Harshana S. De Silva Feelixge; Nixon Niyonzima; Harlan L. Pietz; Martine Aubert; Dan Stone; **Keith R. Jerome**

Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US

401 Enhancing Anti-HIV Gene Therapy: Combining MegaTAL Nuclease Gene Editing With Selection Cassettes

Biswajit Paul[2]; Alexander Astrakhan[3]; Patrick Younan[2]; Blythe D. Sather[4]; Jordan Jarjour[3]; Guillermo Romano[2]; John P. Kowalski[2]; Iram Khan[4]; David J. Rawlings[4]; Hans-Peter Kiem[2]

[1]Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US; [2]Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US; [3]BluebirdBio, Cambridge, MA, US; [4]Seattle Children's Research Institute, Seattle, WA, US

402 A Phase I Clinical Trial of Autologous CD4+ T Cells Modified With a Retroviral Vector Expressing the MazF Endoribonuclease in Patients With HIV-1

Jeffrey M. Jacobson[1]; Hideto Chono[2]; Meghan Metz[1]; Gabriela Plesa[3]; Julie Jadlowsky[3]; Simon Lacey[3]; Bruce Levine[3]; Hirofumi Yoshioka[2]; Junichi Minemo[2]; Carl H. June[3]

[1]Drexel University College of Medicine, Philadelphia, PA, US; [2]Takara Bio Inc., Shiga, Japan; [3]University of Pennsylvania, Philadelphia, PA, US

403 CRISPRs Are Able to Efficiently Target Latent HIV and Halt New Infections

Robert Jan Lebbink; Dorien de Jong; Femke Wolters; Emmanuel J. Wiertz; **Monique Nijhuis**

University Medical Center Utrecht, Utrecht, Netherlands

TUESDAY, FEBRUARY 24, 2015

Session P-F6 Poster Session **Poster Hall**

2:30 pm – 4:00 pm

HDAC Inhibitors

404 Histone Deacetylase (HDAC) and Histone Acetyltransferase (HAT) Inhibitors Have Opposing Effects on Cellular Susceptibility to HIV Infection

Mark B. Lucera[2]; Curtis Dobrowolski[1]; Jonathan Karn[1]; John C. Tilton[2]

[1]Case Western Reserve University, Cleveland Heights, OH, US; [2]Case Western Reserve University, Cleveland, OH, US

405 Panobinostat Dosing Has Broad but Transient Immunomodulatory Effects in HIV Patients

Martin Tolstrup[1]; Christel R. Brinkmann[1]; Thomas A. Rasmussen[1]; Rikke Olesen[1]; Anne Sofie Kjær[1]; Mathias Lichterfeld[2]; Charles Dinarello[3]; Lars Østergaard[1]; Ole S. Søgaard[1]

[1]Aarhus University Hospital, Aarhus, Denmark; [2]Ragon Institute of MIT, MGH and Harvard, Boston, MA, US; [3]University of Colorado, Denver, CO, US

406 Multi-Dose Romidepsin in SIV-Infected RMs Reactivates Latent Virus in Absence of ART

Benjamin Policicchio[1]; Egidio Brocca-Cofano[1]; Cuiling Xu[1]; Dongzhu Ma[1]; Hui Li[2]; George Richter-Haret[1]; Tammy Dunsmore[1]; George M. Shaw[2]; Ivona Pandrea[1]; Cristian Apetrei[1]

[1]University of Pittsburgh, Pittsburgh, PA, US; [2]University of Pennsylvania, Philadelphia, PA, US

407 Suberanilohydroxamic Acid (SAHA)-Induced Histone Modifications in the HIV Promoter in a Human, Primary CD4 T Cell Model of Latency

Brian Reardon[1]; Amey Mukim[2]; Savitha Deshmukh[2]; Christopher H. Woelk[3]; Douglas D. Richman[1]; Celsa A. Spina[1]

[1]University of California San Diego, La Jolla, CA, US; [2]VA San Diego Healthcare System, La Jolla, CA, US; [3]University of Southampton, Southampton, United Kingdom

408 Donor-to-Donor Variation in the Host Gene Expression Response to SAHA

Bastiaan Moesker[1]; Brian Reardon[2]; Nadejda Beliakova-Bethell[2]; Akul Singhania[1]; Michael S. Breen[1]; Christopher H. Woelk[1]

[1]University of Southampton, Southampton, United Kingdom; [2]University of California San Diego, La Jolla, CA, US

409 Off-Target Effects of SAHA May Inhibit HIV Activation

Cory H. White[1]; Harvey E. Johnston[2]; Antigoni Manousopoulou[2]; Celsa A. Spina[1]; Douglas D. Richman[1]; Spiros D. Garbis[2]; Christopher H. Woelk[2]; Nadejda Beliakova-Bethell[1]

[1]University of California San Diego, La Jolla, CA, US; [2]University of Southampton, Southampton, United Kingdom

410 Bystander Effect of Histone Deacetylase Inhibitors on HIV-1 Infection

Grant R. Campbell; Rachel S. Bruckman; Yen-Lin Chu; Stephen A. Spector

University of California San Diego, La Jolla, CA, US

411 HIV-1 Reactivation Increases Mitochondrial Priming of the Latent Reservoir

Jeremy A. Ryan[2]; Allison L. Schure[1]; Zelda Euler[3]; Anthony Letai[2]; **Athe Tsibris**[1]

[1]Brigham and Women's Hospital, Harvard Medical School, Cambridge, MA, US; [2]Dana-Farber Cancer Institute, Boston, MA, US; [3]Ragon Institute of MIT, MGH and Harvard, Cambridge, MA, US

Session P-F7 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Pharmacologic Latency-Reactivation Agents

412 Reactivation of HIV Latently Infected T Cells by Targeting Tat IRES Translation

Georges Khoury[1]; Sri Ramarathinam[2]; Charlene Mackenzie[1]; David Yurick[1]; Con Sonza[1]; Tony Purcell[2]; Damian F. Purcell[1]

[1]University of Melbourne At the Peter Doherty Institute for Infection and Immunity, Melbourne, Australia; [2]Monash University/Alfred Hospital, Melbourne, Australia

413 Targeting HIV-1 Latency With a Potent Tat Inhibitor

Guillaume Mousseau[1]; Remi Fromentin[2]; Cari Kessing[2]; Lydie Trautmann[2]; Nicolas Chomont[2]; **Susana T. Valente**[1]

[1]The Scripps Reasearch institute, Jupiter, FL, US; [2]The Vaccine and Gene Therapy Institute, Port Saint Lucie, FL, US

414 Impact of IFNα-2a on the Replication-Competent HIV-1 Reservoir in CD4+ T Cells

Sara Morón-López[2]; Maria Salgado[2]; Dan Ouchi[2]; Mari Carmen Puertas[2]; Toni Jou[3]; Cristina Tural[3]; Jordi Navarro[1]; Mercedes Perez-Bernal[1]; **Manel Crespo**[1]; Javier Martínez-Picado[2]

[1]Hospital Universitari Vall d'Hebron, Barcelona, Spain; [2]AIDS Research Institute irsiCaixa, Barcelona, Spain; [3]Fundació Lluita contra la SIDA, Barcelona, Spain

415 Immune Modulation With Rapamycin as a Potential Strategy for HIV-1 Eradication

Alyssa R. Martin; Robert F. Siliciano

Johns Hopkins University School of Medicine, Baltimore, MD, US

416 Latency Reversing Agents Activate Latent Reservoirs in the Brain of SIV-Infected Macaques

Lucio Gama[1]; Sarah Price[1]; Erin Shirk[1]; Suzanne E. Queen[1]; Ming Li[1]; Brandon Bullock[1]; Stephen Wietgrefe[2]; Luiz Pianowski[3]; M. Christine Zink[1]; Janice Clements[1]

[1]Johns Hopkins University School of Medicine, Baltimore, MD, US; [2]University of Minnesota, Minneapolis, MN, US; [3]Bioqual, Valinhos, Brazil

417 TLR7 Agonist GS-9620 Activates HIV-1 in PBMCs From HIV-Infected Patients on cART

Derek D. Sloan[1]; Alivelu Irrinki[1]; Angela Tsai[1]; Jasmine Kaur[1]; Jay Lalezari[2]; Jeff Murry[1]; Tomas Cihlar[1]

[1]Gilead Sciences, Inc., Foster City, CA, US; [2]Quest Clinical Research, San Francisco, CA, US

418 Baracitinib, Ruxolitinib, Dasatinib Block HIV Replication, Activation, Reactivation

Christina Gavegnano

Emory University, Atlanta, GA, US

419 Ex Vivo Identification of Highly Effective Latency-Reversing Drug Combinations

Gregory M. Laird[1]; C Korin Bullen[1]; Daniel I. Rosenbloom[2]; Alyssa R. Martin[1]; Alison L. Hill[3]; Christine M. Durand[1]; Janet D. Siliciano[1]; Robert F. Siliciano[1]

[1]Johns Hopkins University School of Medicine, Baltimore, MD, US; [2]Columbia University, New York, NY, US; [3]Harvard University, Boston, MA, US

WEDNESDAY, FEBRUARY 25, 2015

Session P-F8 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Latency Models and Assays

420 Investigating Mechanisms of HIV Persistence Using Droplet Digital PCR Approaches

Elizabeth M. Anderson[1]; Robert Gorelick[2]; Shawn Hill[1]; Catherine A. Rhem[5]; Mary Kearney[1]; John W. Mellors[3]; John M. Coffin[4]; Mike Piatak[2]; Frank Maldarelli[1]

[1]National Cancer Institute at Frederick, Frederick, MD, US; [2]Leidos Biomedical Research, Inc, Frederick, MD, US; [3]University of Pittsburgh, Pittsburgh, PA, US; [4]Tufts University, Boston, MA, US; [5]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD, US

421LB High-Throughput Single-Cell Quantification of HDACi-Based HIV Reservoir Reactivation

Robert W. Yucha[1]; Emily Hanhauser[2]; Kristen S. Hobbs[2]; Helen Bae[3]; Fatih Inci[4]; Hadi Shafiee[2]; Shuqi Wang[4]; Daniel Kuritzkes[1]; Utkan Demirci[4]; Timothy J. Henrich[1]

[1]Brigham and Women's Hospital, Harvard Medical School, Cambridge, MA, US; [2]Brigham and Women's Hospital, Cambridge, MA, US; [3]Harvard University, Cambridge, MA, US; [4]Stanford University, Palo Alto, CA, US

422 Evaluation of HIV-1 Latency-Reversing Agents by a Modified Virus Growth Assay (VOA)

Riddhima Banga; Francesco Procopio; Matthias Cavassini; Alessandra Noto; Song Ding; Giuseppe Pantaleo; **Matthieu Perreau**

Lausanne University Hospital, Epalinges, Switzerland

423 "Kick and Kill" of Latent HIV-1 Infection in Naïve and Central Memory CD4+ T cells

Jennifer M. Zerbato; Nicolas Sluis-Cremer

University of Pittsburgh, Pittsburgh, PA, US

424 HIV Recombination in the In Vitro T_{CM} Latency Model – Reasons and Solutions

Pawel Bonczkowski[2]; Laura J. Martins[1]; Ward de Spiegelaere[2]; Alberto Bosque[1]; Eva Malatinkova[2]; Christopher H. Woelk[3]; Cory H. White[4]; Adam M. Spivak[5]; Vicente Planelles[1]; Linos Vandekerckhove[2]

[1]University Of Utah School of Medicine, Salt Lake City, UT, US; [2]Ghent University and University Hospital, Ghent, Belgium; [3]University of Southampton, Southampton, United Kingdom; [4]University of California San Diego (UCSD), La Jolla, CA, US; [5]Utah University Hospital, Salt Lake City, UT, US

425 CD4+ Tissue-Resident Memory T Cells Are an Important Reservoir for HIV Persistence

Angela R. Wahl; J. Victor Garcia

University of North Carolina, Chapel Hill, NC, US

426 HIV-1 Reprograms Resting CD4 T Cells via Foxo1 and L-Selectin Suppression

Benjamin Trinité[1]; Chi N. Chan[1]; Caroline S. Lee[1]; Joy Folkvord[2]; Elizabeth Connick[2]; **David N Levy**[1]

[1]New York University, New York, NY, US; [2]University of Colorado Anschutz Medical Campus, Aurora, CO, US

427 Measurements of Viral Transcription in Elite Suppressor CD4+ T Cells

Christopher W. Pohlmeyer; C. Korin Bullen; Greg Laird; Alyssa R. Martin; Victoria Walker-Sperling; Stanley U. Chioma; Robert F. Siliciano; Joel Blankson

Johns Hopkins University School of Medicine, Baltimore, MD, US

428LB Short-Term Disulfiram to Reverse Latent HIV Infection: A Dose Escalation Study

Julian H. Elliott[1]; James H. McMahon[1]; Wendy Hartogensis[2]; Namandje Bumpus[3]; Christina Chang[4]; Sulggi A. Lee[2]; Jeff Lifson[5]; Peter Bacchetti[2]; Steven Deeks[2]; Sharon R. Lewin[4]
on behalf of the Disulfiram Study investigators

[1]Monash University/Alfred Hospital, Melbourne, Australia; [2]University of California San Francisco, San Francisco, CA, US; [3]Johns Hopkins University, Baltimore, MD, US; [4]University of Melbourne, Melbourne, Australia; [5]National Cancer Institute, Frederick, MD, US

Session P-F9 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Stem Cell Transplantation

429 Impact of Combination of Chemotherapy and Autologous Hematopoietic Stem-Cell Transplantation for Lymphoma on HIV Reservoir Persistence

Heloise Delagreverie; laurence Gerard; Marie Laure Chaix; Marie Laure Nere; Lionel Galicier; Francois Simon; Eric Oksendenhendler; Constance Delaugerre

Hôpital Saint-Louis, APHP, Université Paris Diderot, Paris, France

430 HIV-1 Reservoirs and Humoral Immunity in Allogeneic Stem Cell Transplantation Patients

Kathryn E. Stephenson[1]; George H. Neubauer[1]; Emily Hanhauser[2]; Marcelo J. Wolff[3]; Cristian Carvallo[3]; Francisco M. Marty[4]; Steven G. Deeks[5]; Daniel R. Kuritzkes[6]; Dan H. Barouch[1]; Timothy J. Henrich[6]

[1]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, US; [2]Brigham and Women's Hospital, Boston, MA, US; [3]Clinica Santa Maria, Santiago, Chile; [4]Dana-Farber Cancer Institute, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, US; [5]University of California San Francisco (UCSF), San Francisco, CA, US; [6]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, US

431 Breakthrough of Preexisting X4-Capable HIV After Allogeneic Stem-Cell Transplantation

Jens Verheyen[1]; Alexander Thielen[2]; Miriam Dirks[1]; Nadine Lübke[3]; Marek Widera[1]; Lambros Kordelas[1]; Martin Däumer[2]; Rolf Kaiser[3]; Stefan Esser[1]

[1]University Hospital Essen, University Duisburg-Essen, Essen, Germany; [2]Institute of Immunology and Genetics, Kaiserslautern, Germany; [3]University of Cologne, Cologne, Germany; [4]University Hospital Essen, University Duisburg-Essen, Essen, Germany; [5]University Hospital Essen, University Duisburg-Essen, Essen, Germany

432 Allogeneic Transplantation With CCR5 Δ32/Δ32 Cord Blood Hematopoietic Cells in an HIV-1-Infected Patient

Rafael Duarte[1]; **Maria Salgado**[2]; Isabel Sanchez-Ortega[1]; Sara Morón-López[2]; Maria C. Puertas[2]; Lawrenze D. Petz[4]; Sergi Querol[3]; Bonaventura Clotet[2]; Javier Martínez-Picado[2]

[1]Institut Català d'Oncologia, L'Hospitalet del Llobregat, Spain; [2]IrsiCaixa Institute for AIDS Research, Badalona, Spain; [3]Barcelona Cord Blood Bank, Barcelona, Spain; [4]StemCyte International Cord Blood Center, Covina, CA, US

433 CCR5 Editing in Hematopoietic Stem Cells in a Nonhuman Primate Model of HIV/AIDS

Christopher W. Peterson[1]; Jianbin Wang[2]; Patricia Polacino[3]; Michael C. Holmes[2]; Shiu-Lok Hu[3]; Philip D. Gregory[2]; Hans-Peter Kiem[1]

[1]Fred Hutchinson Cancer Research Center, Seattle, WA, US; [2]Sangamo BioSciences, Inc., Richmond, CA, US; [3]University of Washington, Seattle, WA, US

434 Cytoxan Enhancement of SB-728-T Engraftment: A Strategy to Improve Anti-HIV Response

Gary Blick[2]; Jay Lalezari[3]; Ricky Hsu[4]; Erin DeJesus[5]; Trevor Hawkins[6]; Ronald T. Mitsuyasu[7]; Shelley Wang[1]; Gary Lee[1]; **Winson Tang**[1]; Dale Ando[1]

[1]Sangamo BioSciences, Inc., Richmond, CA, US; [2]CIRCLE CARE Center, Norwalk, CT, US; [3]Quest Clinical Research, San Francisco, CA, US; [4]New York University School of Medicine, New York, NY, US; [5]Orlando Immunology Center, Orlando, FL, US; [6]Southwest Care Center, Santa Fe, NM, US; [7]University of California Los Angeles CARE Center, Los Angeles, CA, US

TUESDAY, FEBRUARY 24, 2015

Session P-G1 Poster Session — Poster Hall

2:30 pm – 4:00 pm

CNS Reservoirs

435 Highly Precise Measurements of HIV DNA in CSF and Blood by Droplet Digital PCR

Michelli Faria de Oliveira[1]; Sara Gianella[1]; Scott Letendre[2]; Konrad Scheffler[1]; Sergei L. Kosakovsky Pond[1]; Davey M. Smith[1]; Matt Strain[1]; Ronald J. Ellis[2]

[1]University of California San Diego, La Jolla, CA, US; [2]HIV Neurobehavioral Research Center, San Diego, CA, US

436 Antiretroviral Concentrations in Brain Tissue Are Similar to or Exceed Those in CSF.

Namandjé Bumpus[2]; Qing Ma[4]; David J. Moore[1]; Brookie M. Best[1]; Ronald J. Ellis[1]; Cristian L. Achim[1]; Melanie Crescini[1]; Courtney Fletcher[3]; Igor Grant[1]; **Scott Letendre**[1]
The CNTN Group

[1]University of California San Diego, San Diego, CA, US; [2]Johns Hopkins University School of Medicine, Baltimore, MD, US; [3]University of Nebraska Medical Center, Omaha, NE, US; [4]University at Buffalo, Buffalo, NY, US

437 HIV DNA Peripheral Reservoirs Have a Nonlinear Impact on Brain Pathology

William Hey-Cunningham[2]; Nadene Dermody[3]; Phillip Chan[4]; Bruce Brew[5]; Kersten Koelsch[2]; **Lucette A. Cysique**[1]

[1]NeuRA, University of New South Wales, Randwick, Australia; [2]Kirby Institute, University of New South Wales, Sydney, Australia; [3]Macquarie University, Sydney, Australia; [4]Queen Elizabeth Hospital, HKSAR, Hong Kong, China; [5]St. Vincent's Hospital, University of New South Wales, Sydney, Australia

438 Acute HIV CSF/Plasma RNA Ratios Are Variable and Greater Than in Chronic HIV

Joanna Hellmuth[1]; Serena Spudich[2]; Eugene Kroon[3]; Naponpon Sailasuta[4]; Somprartthana Rattanamanee[3]; Sukalaya Lerdlum[5]; Linda L. Jagodzinski[6]; Shelly J. Krebs[7]; Jintanat Ananworanich[8]; **Victor G. Valcour**[1]
The RV254/SEARCH010 Study Group

[1]University of California San Francisco, San Francisco, CA, US; [2]Yale University School of Medicine, New Haven, CT, US; [3]Thai Red Cross AIDS Research Centre, Bangkok, Thailand; [4]University of Hawaii, Honolulu, HI, US; [5]Chulalongkorn University, Bangkok, Thailand; [6]Walter Reed Army Institute of Research, Silver Spring, MD, US; [7]Henry M. Jackson Foundation for the Advancement of Military Medicine, Silver Spring, MD, US; [8]US Military HIV Research Program, Bethesda, MD, US

439 Greater CSF HIV Reduction and CSF Rapid Decay Associated with Improved Neurocognition

Kevin R. Robertson[1]; Natalie M. Bowman[1]; Sarah B. Joseph[1]; Prema Menezes[1]; Nisha Bhatia[2]; Christopher Lippincott[1]; Michael Vinikoor[1]; Joseph Eron[1]; Ronald Swanstrom[1]; Richard Price[2]
THINC UNC

[1]University of North Carolina, Chapel Hill, Chapel Hill, NC, US; [2]University of California San Francisco, San Francisco, CA, US

440 HIV-1 Replication in the CNS Is Associated With Increased Neurocognitive Impairment

Sarah B. Joseph[1]; Laura Kincer[1]; Natalie M. Bowman[1]; Prema Menezes[1]; Kevin Robertson[1]; Albert M. Anderson[2]; David W. Loring[3]; Joseph J. Eron[1]; Richard W. Price[4]; Ronald Swanstrom[1]

[1]University of North Carolina, Chapel Hill, Chapel Hill, NC, US; [2]Emory University, Atlanta, GA, US; [3]Emory University, Atlanta, GA, US; [4]University of California San Francisco, San Francisco, CA, US; [5]University of North Carolina, Chapel Hill, Chapel Hill,, NC, US

Session P-G2 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Optimizing ART for HAND Treatment and Prevention

441 Maraviroc-Enhanced CART Improves Cognition in Virally Suppressed HAND: A Pilot Study

Thomas M. Gates[1]; Lucette A. Cysique[2]; Joga Chaganti[1]; Krista J. Siefried[1]; **Bruce J. Brew**[1]

[1]St Vincent's Hospital, Sydney, Sydney, Australia; [2]Neuroscience Research Australia (NeuRA), Sydney, Australia

442 Similar Neurocognitive Performance in Patients on ATV/r Monotherapy vs Triple Therapy

Giada Caramatti[1]; Francesca Ferretti[1]; Antonio Di Biagio[2]; Amedeo Capetti[3]; Andrea Antinori[4]; Fiorella Di Sora[5]; Roberta Gagliardini[6]; Concetta Vinci[1]; Adriano Lazzarin[1]; **Laura Galli**[1]

[1]San Raffaele Scientific Institute, Milan, Italy; [2]Azienda Ospedaliera San Martino, Genoa, Italy; [3]L. Sacco University Hospital, Milan, Italy; [4]National Institute for Infectious Diseases IRCCS Lazzaro Spallanzani, Rome, Italy; [5]Ospedale San Giovanni, Rome, Italy; [6]Catholic University of the Sacred Heart, Rome, Italy

443 Cerebrospinal Fluid Markers in Long-Term Atazanavir/Ritonavir Monotherapy

Francesca Ferretti; Alba Bigoloni; Valeria Longo; Laura Galli; Laura Passeri; Simonetta Gerevini; Vincenzo Spagnuolo; Adriano Lazzarin; Paola Cinque; Antonella Castagna

San Raffaele Scientific Institute, Milan, Italy

444 Neurocognitive Decline Is Associated With Antiretroviral Concentrations in Plasma and Cerebrospinal Fluid (CSF)

Qing Ma[1]; Xia Liu[2]; Robert Heaton[1]; Fujie Zhang[2]; Hua Jin[1]; Hao Wu[2]; Melanie Crescini[1]; Hongxin Zhao[2]; Hui Zeng[2]; Scott Letendre[1]

[1]University of California San Diego, San Diego, CA, US; [2]Chinese Center for Disease Control and Prevention, Beijing, China

445 Viral Decay Rate in the Cerebrospinal Fluid After Initiating Antiretroviral Therapy

Natalie M. Bowman[1]; Sarah B. Joseph; Prema Menezes[1]; Jessica Margolis[1]; Christopher Lippincott[1]; Michael J. Vinikoor[1]; Kevin R. Robertson[1]; Richard Price[2]; Ronald Swanstrom[1]; Joseph Eron[1]

[1]University of North Carolina, Chapel Hill, NC, US; [2]University of California San Francisco (UCSF), San Francisco, CA, US

446 Rates of Nonconfounded HIV-Associated Neurocognitive Disorder After Early cART

Teresa H. Evering[1]; Allison Applebaum[2]; Melissa La Mar[1]; Donald Garmon[1]; David Dorfman[3]; Martin Markowitz[1]

[1]Aaron Diamond AIDS Research Center, an Affiliate of the Rockefeller University, New York, NY, US; [2]Memorial Sloan-Kettering Cancer Center, New York, NY, US; [3]Mount Sinai School of Medicine, New York, NY, US

447 The Impact of HAART CNS Penetration Effectiveness on Brain Integrity in HIV+ Adults

Laurie Baker[1]; Robert H. Paul[1]; Jodi M. Heaps[1]; Mario Ortega[2]; Christin Usher[1]; Jee Yoon Chang[2]; Beau Ances[2]

[1]University of Missouri St Louis, St Louis, MO, US; [2]Washington University School of Medicine, St Louis, MO, US

448 Efavirenz Use is Not Associated with Increased Risk of Neuropsychological Impairment

Sean B. Rourke[1]; John Gill[2]; Anita Rachlis[1]; Colin Kovacs[4]; Gordon Arbess[5]; Jason Brunetta[4]; Adriana Carvalhal[1]; Chris Power[2]; Ann N. Burchell[3]; Tsegaye Bekele[3]

[1]University of Toronto, Toronto, Canada; [2]University of Alberta, Calgary, Canada; [3]The Ontario HIV Treatment Network, Toronto, Canada; [4]Maple Leaf Medical Clinic, Toronto, Canada; [5]St. Michael's Hospital, Toronto, Canada

449 Quantitative Electroencephalogram as a Translational Biomarker for NNRTI CNS AEs

Pamela Tannenbaum; Jacquelyn Binns; Spencer Tye; Alan Savitz; Steven Fox; Christopher Burgey; Ming-tain Lai; Arthur Simen; daria hazuda; **Michael D. Miller**

Merck and Co, Inc, West Point, PA, US

450 Neurocognition Following Antiretroviral Initiation in Behaviorally HIV-Infected Youth

Sharon Nichols[1]; Patricia Garvie[2]; Tiandong Li[3]; Weijia Ren[3]; Bill Kapogiannis[4]; Bret Rudy[5]; John Sleasman[6]; Steven Woods[7]; Ana Puga[2]

The Adolescent Medicine Trials Network for HIV/AIDS Interventions

[1]University of California San Diego, La Jolla, CA, US; [2]Children's Diagnostic & Treament Center, Inc., Ft. Lauderdale, FL, US; [3]Westat, Inc., Rockville, MD, US; [4]National Institutes of Health (NIH), Bethesda, MD, US; [5]New York University, New York, NY, US; [6]Duke University, Durham, NC, US; [7]University of California, San Diego, La Jolla, CA, US

WEDNESDAY, FEBRUARY 25, 2015

Session P-G3 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Neurologic Disorders in Resource-Limited Settings

451 Neurocognitive Impairment in Diverse Resource-Limited Settings: The International Neurological Study ACTG A5199 and A5271

Kevin R. Robertson[1]; Hongyu Jiang[2]; Scott Evans[2]; Christina Marra[4]; Baiba Berzins[3]; James Hakim[5]; Ned Sacktor[6]; Thomas Campbell[7]; Ann Walawander[8]; Jeff Schouten[4]

On behalf of ACTG 5199 and 5271

[1]University of North Carolina Chapel Hill, Chapel Hill, NC, US; [2]Harvard University, Boston, MA, US; [3]Northwestern University, Chicago, IL, US; [4]University of Washington, Seattle, WA, US; [5]University of Zimbabwe, College of Health Sciences, Harare, Zimbabwe; [6]Johns Hopkins University, Baltimore, MD, US; [7]University of Colorado, Denver, CO, US; [8]Frontier Science, Amherst, NY, US; [9]University of Washington, Seattle, WA, US

452 High Frequency of Dementia in Antiretroviral-Naïve HIV+ Individuals in Rural Uganda

Ned Sacktor[1]; Deanna R. Saylor[1]; Gertrude Nakigozi[2]; Noeline Nakasujja[3]; Xiangrong Kong[4]; Kevin Robertson[5]; Ronald H. Gray[4]; Maria J. Wawer[4]

[1]Johns Hopkins University School of Medicine, Baltimore, MD, US; [2]Rakai Health Sciences Program, Entebbe, Uganda; [3]Makerere University College of Health Sciences, Kampala, Uganda; [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [5]University of North Carolina, Chapel Hill, NC, US

453 Validation of the International HIV Dementia Scale Screening Tool for HAND in Uganda

Megan M. Hosein[1]; Deanna Saylor[1]; Gertrude Nakigozi[2]; Noeline Nakasujja[3]; Xiangrong Kong[4]; Kevin Robertson[5]; Ronald H. Gray[4]; Maria J. Wawer[4]; Ned Sacktor[1]

[1]Johns Hopkins University School of Medicine, Baltimore, MD, US; [2]Rakai Health Sciences Program, Kalisizo, Uganda; [3]Makerere University College of Health Sciences, Kampala, Uganda; [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [5]University of North Carolina Chapel Hill, Chapel Hill, NC, US

454 Cerebrospinal Fluid Cytokines and HIV-Associated Neurocognitive Disorders in Uganda

Mahsa Abassi[1]; Gertrude Nakigozi[3]; Noeline Nakasujja[2]; Xiangrong Kong[4]; David B. Meya[2]; Kevin Robertson[5]; Ronald H. Gray[4]; Maria J. Wawer[5]; Ned Sacktor[5]; David R. Boulware[1]

[1]University of Minnesota, Minneapolis, MN, US; [2]Infectious Disease Institute, Kampala, Uganda; [3]Rakai Health Sciences Program, Entebbe, Uganda; [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [5]Johns Hopkins University School of Medicine, Baltimore, MD, US

455 A Comparison of 5 Brief Screening Tools for HAND in the USA and South Africa

John A. Joska[1]; Jade Witten[1]; Kevin Thomas[1]; Corne Robertson[1]; Martine Casson-Crook[1]; Heidi Roosa[2]; Jason Creighton[2]; Jennifer Lyons[3]; Justin McArthur[2]; **Ned Sacktor**[2]

[1]University of Cape Town, Cape Town, South Africa; [2]Johns Hopkins University School of Medicine, Baltimore, MD, US; [3]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, US

456 Subtype Associations With HIV-Associated Neurocognitive Dysfunction

Tyler R. Day; Davey M. Smith; Robert Heaton; Donald Franklin; Myres W. Tilghman; Josué Pérez-Santiago

University of California San Diego, San Diego, CA, US

457 Peripheral Neuropathy at First-Line Failure and on Second Line in Sub-Saharan Africa

Alejandro Arenas-Pinto[1]; Jennifer Thompson[1]; Godfrey Musoro[4]; Helen Mussana[5]; Abbas Lugemwa[3]; Andrew D. Kambugu[2]; Aggrey Mweemba[6]; Sarah Walker[1]; Paton Nicholas[1]
On behalf of the EARNEST Trial Team

[1]University College London, London, United Kingdom; [2]Makerere University, Kampala, Uganda; [3]Joint Clinical Research Centre, Mbarara, Uganda; [4]University of Zimbabwe, Harare, Zimbabwe; [5]Joint Clinical Research Centre, Kampala, Uganda; [6]University Teaching Hospital, Lusaka, Zambia

458 Prevalence of and Risk Factors for Peripheral Neuropathy in Rakai, Uganda

Deanna R. Saylor[1]; Gertrude Nakigozi[2]; Noeline Nakasujja[3]; Xiangrong Kong[4]; Kevin Robertson[5]; Ronald H. Gray[4]; Maria J. Wawer[4]; Ned Sacktor[1]

[1]Johns Hopkins School of Medicine, Baltimore, MD, US; [2]Rakai Health Sciences Program, Entebbe, Uganda; [3]Makerere University College of Health Sciences, Kampala, Uganda; [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [5]University of North Carolina, Chapel Hill, NC, US

459 Predictors of Cognitive Performance Among HIV-Infected Patients in East Africa

Victor G. Valcour[1]; Francis Kiweewa[2]; Rosemary Namagembe[2]; Rither Langat[3]; Samoel Khamadi[4]; Kyra Hansson[1]; Christina S. Polyak[5]; Julie Ake[5]
On behalf of the RV329 AFRICOS Study Team

[1]University of California San Francisco, San Francisco, CA, US; [2]Walter Reed Project, Kampala, Uganda; [3]Walter Reed Project, Kericho, Kenya; [4]Walter Reed Project - Tanzania, Mbeya, United Republic of Tanzania; [5]Walter Reed Army Institute of Research, Silver Spring, MD, US

THURSDAY, FEBRUARY 26, 2015

Session P-G4 Poster Session — Poster Hall

2:30 pm – 4:00 pm

HAND Genetics

460 Mitochondrial DNA Haplogroups and CSF Neuroinflammation in the CHARTER Cohort

Todd Hulgan[4]; David Samuels[4]; Ronald J. Ellis[1]; William Bush[2]; Scott Letendre[1]; Donald Franklin[1]; Igor Grant[1]; Asha R. Kallianpur[3]
CHARTER Group

[1]University of California San Diego, San Diego, CA, US; [2]Case Western Reserve University, Cleveland, OH, US; [3]Cleveland Clinic Foundation, Lerner Research Institute, Cleveland, OH, US; [4]Vanderbilt University, Nashville, TN, US

461 Iron-Regulatory Genes Are Associated With Neuroimaging Traits in HIV Infection

Tricia A. Thornton-Wells[2]; Christine Fennema-Notestine[3]; Todd Hulgan[4]; Scott Letendre[5]; Ronald J. Ellis[6]; **Asha R. Kallianpur**[1]; for the CHARTER Group[7]

[1]Cleveland Clinic/Lerner Research Institute, Cleveland, OH, US; [2]Vanderbilt University School of Medicine, Nashville, TN, US; [3]University of California San Diego, San Diego, CA, US; [4]Vanderbilt University School of Medicine, Nashville, TN, US; [5]University of California San Diego, San Diego, CA, US; [6]University of California San Diego, San Diego, CA, US; [7]University of California San Diego (UCSD), San Diego, CA, US

462 Synergistic Effects of *MBL2*/*APP* Polymorphisms on Neurocognitive Impairment in CHARTER

Kumud Singh; Qianqian Deng; Christine Fennema-Notestine; Florin Vaida; Ronald Ellis; Scott Letendre; Donald Franklin; Debralee Rosario; Robert Heaton; Igor Grant
CHARTER

University of California San Diego, La Jolla, CA, US

463 No Association Between Apoε4, HIV Infection, Age, Cognitive Outcome or Death

James T. Becker[1]; Jeremy J. Martinson[1]; Sudhir Penugonda[2]; Lawrence Kingsley[1]; Samantha A. Molsberry[1]; Sandra Reynolds[3]; Andrew Levine[4]; Eileen Martin[5]; Cynthia A. Munro[6]; Ned Sacktor[6]

[1]University of Pittsburgh, Pittsburgh, PA, US; [2]Northwestern University, Feinberg School of Medicine, Chicago, IL, US; [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [4]David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA, US; [5]Rush University Medical Center, Chicago, IL, US; [6]Johns Hopkins University School of Medicine, Baltimore, MD, US

464 Bridging Genetics, Histopathology, and Neurocognition in the Context of HAND

Andrew Levine[1]; Virawudh Soontornniyomkij[2]; Cristian L. Achim[2]; Ben Gouaux[2]; Eliezer Masliah[2]; Janet Sinsheimer[3]; Elyse Singer[1]; David J. Moore[2]

[1]University of California Los Angeles, Long Beach, CA, US; [2]University of California San Diego, San Diego, CA, US; [3]University of California Los Angeles, Los Angeles, CA, US

TUESDAY, FEBRUARY 24, 2015

Session P-G5 Poster Session — Poster Hall

2:30 pm – 4:00 pm

HAND Diagnosis and Predictors

465 Relative Risk and Factors Associated With Progression to Symptomatic HAND

Sean B. Rourke[1]; John Gill[2]; Anita Rachlis[1]; Colin Kovacs[3]; Gordon Arbess[5]; Jason Brunetta[3]; Adriana Carvalhal[5]; Chris Power[2]; Ann N. Burchell[4]; Tsegaye Bekele[4]

[1]University of Toronto, Toronto, Canada; [2]University of Alberta, Calgary, Canada; [3]Maple Leaf Medical Clinic, Toronto, Canada; [4]The Ontario HIV Treatment Network, Toronto, Canada; [5]St. Michael's Hospital, Toronto, Canada

466 Monocytes Activation Characterizes Immune Failure but Not Cognitive Impairment on ART

Antonio Muscatello[1]; Davide Mangioni[1]; Paolo Perseghin[2]; Arianna Incontri[2]; Alessandro Soria[1]; Nicola Squillace[1]; Giuseppe Lapadula[1]; Sebastiano Leone[1]; Andrea Gori[1]; **Alessandra Bandera**[1]

[1]S. Gerardo Hospital, Monza, Italy; [2]San Gerardo Hospital–UOS Aferesi e Nuove Tecnologie Trasfusionali–SIMT, Monza, Italy

467 The VACS Index Predicts Change in Neurocognitive Functions in People With HIV

Sean B. Rourke[1]; John Gill[2]; Anita Rachlis[1]; Amy Justice[7]; Colin Kovacs[3]; Gordon Arbess[4]; Jason Brunetta[3]; Adriana Carvalhal[4]; Chris Power[6]; Ann N. Burchell[5]

[1]University of Toronto, Toronto, Canada; [2]University of Alberta, Calgary, Canada; [3]Maple Leaf Medical Clinic, Toronto, Canada; [4]St. Michael's Hospital, Toronto, Canada; [5]The Ontario HIV Treatment Network, Toronto, Canada; [6]University of Alberta, Edmonton, Canada; [7]Yale University School of Medicine, New Haven, CT, US

468 When Diagnosing HAND, Should Visuospatial Functioning be Evaluated?

Talia Shirazi[1]; Angela Summers[1]; Sally Steinbach[2]; Suad Kapetanovick[1]; Avindra Nath[2]; Bryan Smith[2]; Joseph Snow[1]

[1]National Institute of Mental Health (NIMH), Bethesda, MD, US; [2]National Institute of Neurological Disorders and Stroke, Bethesda, MD, US

469 Predictors of Neurocognitive Decline Among Aviremic Individuals in the CHARTER Cohort

Marie-Josée Brouillette[1]; Tracy Yuen[2]; Susan C. Scott[2]; Lesley K. Fellows[3]; Robert Heaton[4]; Scott Letendre[4]; Ronald J. Ellis[4]; Nancy Mayo[2]
the CHARTER group

[1]McGill University Health Centre, Montreal, Canada; [2]McGill University Health Centre, Montreal, Canada; [3]Montreal Neurological Hospital, Montreal, Canada; [4]University of California San Diego, San Diego, CA, US

470 Association Between Plasma Homocysteine Levels and Neuronal Injury in Untreated HIV

Erika Ahlgren[1]; Lars Hagberg[1]; Lars-Magnus Andersson[1]; Staffan Nilsson[2]; Dietmar Fuchs[3]; Henrik Zetterberg[1]; Magnus Gisslén[1]

[1]University of Gothenburg, Gothenburg, Sweden; [2]Chalmers University of Technology, Gothenburg, Sweden; [3]Innsbruck Medical University, Innsbruck, Austria

471 Plasma MicroRNA Profiling Predicts HIV-Associated Neurocognitive Disorder

Eugene L. Asahchop[1]; William G. Branton[1]; Segun M. Akinwumi[2]; Noshin Koenig[3]; Esther Fujiwara[2]; John Gill[3]; Christopher Power[1]

[1]University of Alberta, Edmoton, Canada; [2]University of Alberta, Edmonton, Canada; [3]Southern Alberta Clinic, Calgary, Canada

472 Performance of 4 Tools to Screen for HIV-Associated Cognitive Impairment

Judith Schouten[2]; Tanja Su[2]; **Rosan A. van Zoest**[1]; Ferdinand W. Wit[1]; Ineke G. Stolte[5]; Alan Winston[3]; Peter Reiss[1]; Peter Portegies[4]; Gert J. Geurtsen[2]; Ben A. Schmand[2]

[1]Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands; [2]Academic Medical Center University of Amsterdam, Amsterdam, Netherlands; [3]Imperial College London, London, Netherlands; [4]Onze Lieve Vrouwe Gasthuis, Amsterdam, Netherlands; [5]Public Health Service of Amsterdam, Amsterdam, Netherlands

THURSDAY, FEBRUARY 26, 2015

Session P-G6 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Inflammation and Markers of Brain Injury in HAND

473 Astrocyte and Microglial Activation in Acute and Chronic HIV Pre- and Post-cART

Michael Peluso[1]; Victor G. Valcour[2]; Jintanat Ananworanich[3]; James L. Fletcher[4]; Somporn Tipsuk[4]; Bonnie Slike[3]; Nittaya Phanuphak[4]; Magnus Gisslén[5]; Henrik Zetterberg[5]; **Serena Spudich**[6]

RV254/SEARCH 010 & SEARCH 011 Study Teams

[1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, US; [2]University of California San Francisco, San Francisco, CA, US; [3]Walter Reed Army Institute of Research, Bethesda, MD, US; [4]Thai Red Cross AIDS Research Centre, Bangkok, Thailand; [5]University of Gothenburg, Gothenburg, Sweden; [6]Yale University, New Haven, CT, US

474 CNS Immunoactivation and Neuronal Damage in Patients With Progressive Neurocognitive Impairment

Arvid Edén[1]; Donald Franklin[2]; Henrik Zetterberg[1]; Dietmar Fuchs[3]; Robert Heaton[2]; Scott Letendre[2]; Thomas Marcotte[2]; Richard Price[4]; Igor Grant[2]; Magnus Gisslén[1]

[1]University of Gothenburg, Gothenburg, Sweden; [2]University of California San Diego, San Diego, CA, US; [3]Innsbruck Medical University, Innsbruck, Austria; [4]University of California San Francisco, San Francisco, CA, US

475 Endothelial Function and CNS Measures in Primary HIV Infection Pre and Post Early ART

Sebastian Urday[1]; **Zaina Zayyad**[1]; Julia Peterson[2]; Felicia C. Chow[2]; Kevin R. Robertson[3]; Richard Price[2]; Priscilla Hsue[2]; Serena Spudich[1]

[1]Yale University, New Haven, CT, US; [2]University of California San Francisco, San Francisco, CA, US; [3]University of North Carolina, Chapel Hill, NC, US

476 Platelet-Endothelial Interactions in SIV-Associated CNS Disease

Claire E. Lyons[2]; Hannah Schneider[3]; Liz Engle[1]; Suzanne E. Queen[1]; Craig N. Morrell[4]; Joseph L. Mankowski[1]; **Kelly A. Pate**[1]

[1]Johns Hopkins University School of Medicine, Baltimore, MD, US; [2]Tufts University, North Grafton, MA, US; [3]Colorado State University, Fort Collins, CO, US; [4]University of Rochester, Rochester, NY, US

477 Microbial Translocation Is Associated With Neuroinflammation in HIV Subjects on ART

Jaime H. Vera[1]; Qi Guo[2]; Adriano Boasso[1]; Louise Greathead[1]; James Cole[1]; Courtney Bishop[2]; Rabiner Ilan[2]; Roger Gunn[2]; Paul Matthews[1]; Alan Winston[1]

[1]Imperial College London, London, United Kingdom; [2]Imanova Centre for Imaging Sciences, London, United Kingdom

478 DKK1 Is Associated With HIV-Associated Neurocognitive Impairment

Chunjiang Yu[1]; Melanie Seaton[1]; Scott Letendre[2]; Robert Heaton[2]; **Lena Al-Harthi**[1]

[1]Rush University Medical Center, Chicago, IL, US; [2]University of California at San Diego, San Diego, CA, US

479 Markers of HIV-Associated Cognitive Impairment Are Elevated in HIV-Infected Patients With Neurosyphilis

Emily Ho; Lauren Tantalo; Sharon Sahi; Trudy Jones; Shelia Dunaway; Christina Marra

University of Washington, Seattle, WA, US

480 CD14+ PBMC Secrete Cytokines Linked to HIV-Associated Neurocognitive Disorders

Melissa A. Agsalda-Garcia[4]; Victor G. Valcour[1]; Pasiri Sithinamsuwan[2]; Guangxiang G. Zhang[4]; Cecilia M. Shikuma[4]; James L. Fletcher[3]; Nicholas Hutchings[1]; Alexandra Schuetz[5]; Jintanat Ananworanich[3]; Bruce Shiramizu[4]

[1]University of California San Francisco, San Francisco, CA, US; [2]Phramongkutklao Hospital, Bangkok, Thailand; [3]The Thai Red Cross AIDS Research Centre, Bangkok, Thailand; [4]University of Hawaii, John A. Burns School of Medicine, Honolulu, HI, US; [5]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

481 MBL-HIV1gp120 Immunoreactivity Is Associated With Markers of Neuronal Injury

Carmen Teodorof[1]; Damhnien Nguyen[1]; Nishi Kadakia[1]; Ricky Maung[2]; Benchawanna Soontornniyomkij[1]; Cristian Achim[1]; David Moore[1]; Eliezer Masliah[1]; Marcus Kaul[2]; Kumud Singh[1]

[1]University of California San Diego, San Diego, CA, US; [2]The Sanford Burnham Medical Research Institute, La Jolla, CA, US

WEDNESDAY, FEBRUARY 25, 2015

Session P-G7 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Aging and Cognitive Decline

482 Amyloid Uptake by PET Imaging in Older HIV+ Individuals With Cognitive Impairment

Ned Sacktor; Richard Skolasky; Heidi Roosa; Yun Zhou; Weiguo Ye; Noble George; Dean Wong; Mona Mohamed

Johns Hopkins University School of Medicine, Baltimore, MD, US

483 Lower CSF Amyloid-β Levels Are Associated With Worse Neurocognitive Functioning in HIV-Infected Adults With a Family History of Dementia

Pariya L. Fazeli[1]; David J. Moore[1]; Donald Franklin[1]; Robert Heaton[1]; Christina Marra[2]; Benjamin B. Gelman[3]; Allen McCutchan[1]; Igor Grant[1]; Scott Letendre[1]

[1]University of California San Diego, San Diego, CA, US; [2]University of Washington Seattle, Seattle, WA, US; [3]University of Texas Medical Branch, Galveston, TX, US

484 Cystatin C Is Associated With Neurocognitive Impairment in Older HIV+ Adults

Marissa Sakoda[1]; Pariya L. Fazeli[2]; Scott Letendre[2]; Dilip Jeste[2]; Igor Grant[2]; David J. Moore[2]

[1]John A. Burns School of Medicine at the University of Hawaii, Honolulu, HI, US; [2]University of California San Diego, San Diego, CA, US

485 Leptomeningeal Enhancement on MRI in the Aging HIV-Positive Population

Bryan R. Smith[1]; Sally Steinbach[1]; Govind Nair[1]; Caryn Morse[1]; Joseph Snow[2]; Suad Kapetanovick[2]; Henry Masur[1]; Avindra Nath[1]; Daniel S. Reich[1]

[1]National Institutes of Health, Bethesda, MD, US; [2]National Institute of Mental Health, Bethesda, MD, US; [3]National Institutes of Health, Clinical Center, Bethesda, MD, US

486 Hepatitis C Infection and Cognition in Older HIV+ Adults: Data From the Center of Excellence on Disparities in HIV and Aging (CEDHA)

Oluwatoyin M. Adeyemi[1]; Sue Leurgans[2]; Alan Landay[2]; David Bennett[2]; Lisa Barnes[2]

[1]Ruth M Rothstein CORE Center, Cook County Health and Hospitals System, Chicago, IL, US; [2]Rush University Medical Center, Chicago, IL, US

487 Neurocognitive Screening Tests Are Associated With Cardiovascular Risk and VACS Scores

Andrea Calcagno[1]; Marielisabetta Scarvaglieri[1]; Daniela Vai[2]; Alessandro Livelli[2]; Letizia Marinaro[1]; Giancarlo Orofino[2]; Nicole Pagani[1]; Daniele Imperiale[2]; Giovanni Di Perri[1]; Stefano Bonora[1]

[1]University of Torino, Torino, Italy; [2]ASLTO2, Torino, Italy; [3]ASLTO2, Torino, Italy

488 Aerobic Exercise Attenuates Cognitive Decline and Brain Volume Loss Associated With HIV

Brian Basco[1]; Mario Ortega[1]; Jodi M. Heaps[3]; Laurie Baker[2]; Florin Vaida[4]; Beau Ances[1]

[1]Washington University School of Medicine, St. Louis, MO, US; [2]University of Missouri St. Louis, St. Louis, MO, US; [3]Missouri Institute of Mental Health, St. Louis, MO, US; [4]University of California San Diego, San Diego, CA, US

489 The Impact of Physical Activity on Cognition in Men With and Without HIV

Anne Monroe[1]; Long Zhang[7]; Lisa P. Jacobson[7]; Todd T. Brown[1]; Michael Plankey[4]; Eric Miller[3]; James T. Becker[5]; Eileen Martin[6]; Ned Sacktor[1]
On behalf of the Multicenter AIDS Cohort Study

[1]Johns Hopkins University School of Medicine, Baltimore, MD, US; [2]Johns Hopkins University School of Medicine, Baltimore, MD, US; [3]University of California Los Angeles, Los Angeles, CA, US; [4]Georgetown University, Washington, DC, US; [5]University of Pittsburgh, Pittsburgh, PA, US; [6]Rush University Medical Center, Chicago, IL, US; [7]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US

490 Abnormal Lung Function Associated With Abnormal Brain Structure and Function in HIV

Alison Morris[1]; Lawrence Kingsley[1]; **Matthew Gingo**[1]; Meghan Fitzpatrick[1]; Roger Detels[3]; Oto Martinez[3]; Eric Miller[3]; Jeffrey Alger[3]; Eric Kleerup[3]; James T. Becker[1]

[1]University of Pittsburgh, Pittsburgh, PA, US; [2]University of Pittsburgh, Pittsburgh, PA, US; [3]David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA, US

491 HIV DNA and Neurocognitive Impairment in Older Subjects on Suppressive ART

Michelli Faria de Oliveira[1]; Ben Murrell[1]; Josué Pérez-Santiago[1]; Milenka Vargas[1]; Ronald J. Ellis[2]; Scott Letendre[2]; Igor Grant[2]; Davey M. Smith[1]; Steven P. Woods[2]; Sara Gianella[1]

[1]University of California San Diego, La Jolla, CA, US; [2]HIV Neurobehavioral Research Center, San Diego, CA, US

492 Suppressive ART Is Key to Reduce Neurocognitive Impairment in Aging HIV+ Individuals

Christina C. Yek[1]; David M. Smith[1]; Gabriel Wagner[1]; Susan Morgello[2]; Scott Letendre[1]; Igor Grant[1]; Sergei L. Kosakovsky Pond[1]; Sara Gianella[1]
On behalf of the CHARTER group

[1]University of California San Diego, San Diego, CA, US; [2]Icahn School of Medicine at Mount Sinai, New York, NY, US

493 Mixed Membership Trajectory Model of Cognitive Impairment in the MACS

Samantha A. Molsberry[1]; Fabrizio Lecci[2]; Brian Junker[2]; Sandra Reynolds[3]; Andrew Levine[4]; Eileen Martin[5]; Cynthia A. Munro[6]; Ned Sacktor[6]; James T. Becker[1]; Neuropsychology Working Group O. Multicenter AIDS Cohort Study[7]

[1]University of Pittsburgh, Boston, MA, US; [2]Carnegie Mellon University, Pittsburgh, PA, US; [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [4]University of California Los Angeles, Los Angeles, CA, US; [5]Rush University Medical Center, Chicago, IL, US; [6]Johns Hopkins University School of Medicine, Baltimore, MD, US; [7]National Institutes of Health (NIH), Bethesda, MD, US

494 Brain Structural Correlates of Trajectories to Cognitive Impairment in HIV Disease

James T. Becker[1]; Mikhail Popov[1]; Samantha A. Molsberry[1]; Fabrizio Lecci[2]; Brian Junker[2]; Sandra Reynolds[3]; Eric Miller[4]; Cynthia A. Munro[5]; Ann Ragin[6]; Ned Sacktor[5]

[1]University of Pittsburgh, Pittsburgh, PA, US; [2]Carnegie Mellon University, Pittsburgh, PA, US; [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [4]David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA, US; [5]Johns Hopkins University School of Medicine, Baltimore, MD, US; [6]Northwestern University, Feinberg School of Medicine, Chicago, IL, US

495 Cognitive Reserve and Neuropsychological Functioning in Older HIV-Infected People

Benedetta Milanini[1]; Nicoletta Ciccarelli[1]; Silio Limiti[1]; Pierfrancesco Grima[2]; Massimiliano Fabbiani[1]; Barbara Rossetti[3]; Elena Visconti[1]; Enrica Tamburrini[1]; Roberto Cauda[1]; Simona Di Giambenedetto[1]

[1]Institute of Infectious Diseases, Catholic University of Sacred Hearth, Rome, Italy; [2]Division of Infectious Diseases, "S. Caterina Novella" Hospital, Galatina, Italy; [3]Division of Infectious Diseases, University of Siena, Italy

THURSDAY, FEBRUARY 26, 2015

Session P-G8 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Mitochondrial Dysfunction in HAND and Depression

496 Mitochondrial DNA, Neurologic and Systemic Inflammation, and Immune Dysregulation

Josué Pérez-Santiago; Michelli Faria de Oliveira; Susanna R. Var; Steven P. Woods; Sara Gianella Weibel; Sanjay Mehta; Ben Murrell; Tyler R. Day; Ronald J. Ellis

University of California San Diego, La Jolla, CA, US

497 CSF Metabolomics Implicate Bioenergetic Adaptation as a Neural Mechanism Regulating Shifts in the Cognitive States of HIV-Infected Subjects

Norman J. Haughey[1]; Alex DIckens[1]; Reena Deutsch[2]; Michelle Mielke[3]; Timothy Claridge[4]; Igor Grant[2]; Thomas Marcotte[2]; Scott Letendre[2]; Justin McArthur[1]

[1]Johns Hopkins University School of Medicine, Baltimore, MD, US; [2]University of California San Diego, San Diego, CA, US; [3]Mayo Clinic, Rochester, MN, US; [4]University of Oxford, Oxford, United Kingdom

498 Altered Monoamine and Acylcarnitine Metabolites in HIV Patients with Depression

Edana Cassol[1]; Vikas Misra[2]; Susan Morgello[3]; Gregory D. Kirk[4]; Shruti H. Mehta[4]; Dana H. Gabuzda[2]

[1]Carleton University, Ottawa, Canada; [2]Dana-Farber Cancer Institute, Boston, MA, US; [3]Mount Sinai Hospital, New York, NY, US; [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US

499 Mitochondrial Injury and Cognitive Function in HIV Infection and Methamphetamine

Susanna R. Var; Tyler R. Day; Andrej Vitomirov; Davey M. Smith; Virawudh Soontornniyomkij; Cristian L. Achim; Sanjay Mehta; Josué Pérez-Santiago

University of California San Diego, San Diego, CA, US

500 Efavirenz-Induced Nitric Oxide Affects Mitochondrial Function in Glial Cells

Haryes A. Funes[1]; Fernando Alegre[2]; Miriam Polo[2]; Ana Blas-García[2]; **Juan V. Espluges**[3]; Nadezda Apostolova[4]

[1]Universidad de Valencia, Valencia, Spain; [2]Universidad de Valencia/FISABIO, Valencia, Spain; [3]Universidad de Valencia/FISABIO/CIBERehd, Valencia, Spain; [4]Universidad Jaume I, Castellón, Spain

Session P-G9 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Neuropathogenesis Mechanisms

501 Role of HIV Strain, Accessory Proteins, and Cytokines in Macrophage HO-1 Deficiency

Alexander J. Gill; Patricia J. Vance; Ronald G. Collman; Dennis L. Kolson

University of Pennsylvania, Philadelphia, PA, US

502 Atorvastatin Reverses the HIV-induced HO-1 Defect in Primary Human Macrophages

Melanie R. Duncan; Alexander J. Gill; Anjana Yadav; Dennis L. Kolson; Ronald G. Collman

University of Pennsylvania, Philadelphia, PA, US

503 Enhanced Antagonism of BST-2 by Neurovirulent SIV Envelope

Kenta Matsuda; Chia-Yen Chen; Fan Wu; Ronald Plishka; Alicia Buckler-White; Klaus Strebel; Vanessa M. Hirsch

National Institutes of Health (NIH), Bethesda, MD, US

504 MEMRI Reflects HIV-1-Associated Human Pathobiology in a Rodent NeuroAIDS Model

Aditya N. Bade; Santhi Gorantla; Prasanta K. Dash; Edward Makarov; Balasrinivasa R. Sajja; Larisa Poluektova; Howard Gendelman; Michael Boska; Yutong Liu

University of Nebraska Medical Center, Omaha, NE, US

505 Detectable CSF Tat Despite Dual Compartment HIV Viral Suppression With cART

Bruce Brew[1]; Lucette A. Cysique[2]; Simon Jones[4]; Tory Johnson[3]; Avindra Nath[3]

[1]St Vincent's Hospital, Sydney, Sydney, Australia; [2]Neuroscience Research Australia, Sydney, Australia; [3]National Institute of Neurological Disorders and Stroke, Bethesda, MD, US; [4]St Vincent's Centre for Applied Medical Research, Sydney, Australia

506 DNA Methylation Changes in HIV-Positive Men With Cognitive Decline

Jeremy Martinson; Gregory Joseph; Lawrence Kingsley; James T. Becker
Pitt Mens Study

University of Pittsburgh, Pittsburgh, PA, US

507 HIV Induces Astrocyte Senescence and Is Reversed by Beta-Catenin Induction

Chunjiang Yu; **Victoria Lutgen**; Lena Al-Harthi

Rush University Medical Center, Chicago, IL, US

508 Wnts-Mediated Astrocyte/CD8+ T-Cell Interactions Impacting HIV Neuropathogenesis

Maureen H. Richards[1]; Melanie S. Seaton[1]; Stephanie Kim[2]; Srinivasa Narasipura[1]; Lena Al-Harthi[1]

[1]Rush University Medical Center, Chicago, IL, US; [2]Brown University, Boston, MA, US

TUESDAY, FEBRUARY 24, 2015

Session P-H1 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Pharmacokinetics, Pharmacodynamics, and Adherence

509 HIV-1 Attachment Inhibitor Prodrug BMS-663068: Model-Based Dose Selection

Ishani Savant Landry[1]; Li Zhu[1]; Malaz Abutarif[1]; Matthew Hruska[1]; Brian M. Sadler[2]; Maria Pitsiu[3]; George J. Hanna[1]; David W. Boulton[1]; Richard Bertz[1]

[1]Bristol-Myers Squibb, Princeton, NJ, US; [2]ICON plc, Cary, NC, US; [3]ICON plc, Manchester, United Kingdom

510 Pharmacokinetic and Pharmacodynamic Evaluation of NNRTI IQP-0528 DuoGel™ in Macaques

Lara E. Pereira[1]; Pedro Mesquita[2]; **Anthony Ham**[3]; Tyana Singletary[4]; Janet McNicholl[5]; Karen W. Buckheit[3]; Robert Buckheit[3]; James M. Smith[5]

[1]LifeSource Biomedical LLC,, Moffett Field, CA, US; [2]Albert Einstein College of Medicine, Bronx, NY, US; [3]ImQuest BioSciences,, Frederick, MD, US; [4]Anyar Inc., Fort Walton Beach, FL, US; [5]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US

511 Tenofovir PK in Adults With Renal Dysfunction on LPV/r and NNRTI-Based ART

Tim R. Cressey[1]; Anchalee Avihingsanon[2]; Guttiga Halue[3]; Prattana Leenasirimakul[4]; Praornsuda Sukrakanchana[5]; Anthony T. Podany[6]; Courtney Fletcher[6]; Gonzague Jourdain[5]; Virat Klinbuayaem[7]; Chureeratana Bowonwatanuwong[8]

[1]PHPT-IRD UMI 174 Chiang Mai University/Harvard School of Public Health, Chiang Mai, Thailand; [2]HIV Netherlands Australia Thailand Research Collaboration, Bangkok, Thailand; [3]Phayao Hospital, Phayao, Thailand; [4]Nakornping Hospital, Chiang Mai, Thailand; [5]Chiang Mai University, Chiang Mai, Thailand; [6]University of Nebraska Medical Center, Omaha, NE, US; [7]Sanpatong Hospital, Sanpatong, Thailand; [8]Chonburi Hospital, Chonburi, Thailand

512 Population Pharmacokinetics of Cotrimoxazole West African HIV-Infected Children

Claire Pressiat[1]; Sihem Benaboud[2]; Jean-Marc Treluyer[1]; Véronique Méa-Assande[3]; Caroline Yonaba[4]; Sophie Dattez[5]; Diarra Ye[6]; Yi ZHENG[1]; **Valeriane Leroy**[5]; Déborah HIRT[1]
MONOD ANRS 12206

[1]Paris Descartes University, EA 08, Paris, France; [2]Clinical Pharmacology Department, AP-HP, Paris Centre Hospital Group, Paris, France; [3]Avocatier Health Center, Abidjan, Côte d'Ivoire; [4]Department of Paediatrics, CHU Yalgado Ouedraogo, Ouagadougou, Burkina Faso; [5]Institute of Public Health, Epidemiology and Development (ISPED), University of Bordeaux, Bordeaux, France; [6]Department of Paediatrics, CHU Charles de Gaulle, Université de Ouagadougou, Ouagadougou, Burkina Faso

513 ART Choice Impacts Antimalarial Exposure and Treatment Outcomes in Ugandan Children

Sunil Parikh[2]; Norah Mwebaza[3]; Richard Kajubi[3]; Joshua Ssebuliba[3]; Sylvia Kiconco[3]; Liusheng Huang[1]; Qin Gao[1]; Abel Kakuru[3]; Jane Achan[3]; **Francesca T. Aweeka**[1]

[1]University of California, San Francisco, San Francisco, CA, US; [2]Yale University, New Haven, CT, US; [3]Makerere University College of Health Sciences, Kampala, Uganda

514 Exploring Long-Term Adherence Markers Using Hair and Dried Blood Spots in iPrEX OLE

Monica Gandhi[1]; David V. Glidden[1]; Albert Liu[2]; Peter L. Anderson[7]; Howard Horng[1]; Juan Guanira[3]; Beatriz Grinsztejn[4]; Suwat Chariyalertsak[5]; Linda-Gail Bekker[6]; Robert M. Grant[1]
iPrEX OLE

[1]University of California San Francisco, San Francisco, CA, US; [2]San Francisco Department of Public Health, San Francisco, CA, US; [3]Investigaciones Medicas en Salud, Lima, Peru; [4]Instituto de Pesquisa Clinica Evandro Chagas, Rio de Janeiro, Brazil; [5]Chiang Mai University, Chiang Mai, Thailand; [6]University of Cape Town, Cape Town, South Africa; [7]University of Colorado, Denver, CO, US

Session P-H2 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Pharmacogenomics

515 UGT1A1 Genotype Predicts Bilirubin-Related Discontinuation of Atazanavir/Ritonavir

Saran Vardhanabhuti[1]; Heather J. Ribaudo[1]; Raphael J. Landovitz[2]; Igho Ofotokun[3]; Jeffrey L. Lennox[3]; Judith S. Currier[2]; Lana M. Olson[4]; David W. Haas[4]

[1]Harvard School of Public Health, Center for Biostatistics in AIDS Research, Boston, MA, US; [2]UCLA Center for Clinical AIDS Research & Education, Los Angeles, CA, US; [3]Emory University School of Medicine, Atlanta, GA, US; [4]Vanderbilt University School of Medicine, Nashville, TN, US

516 ABCB1 Polymorphism Affects Tenofovir Exposure as Determined by Areas-Under-the-Time-Concentration-Curve With 24-hour Intensive Pharmacokinetic Monitoring

Sanjiv M. Baxi[1]; Peter Bacchetti[1]; Mardge Cohen[2]; Jack A. Dehovitz[3]; Kathryn Anastos[4]; Stephen J. Gange[5]; Mary A. Young[6]; Monica Gandhi[1]; Bradley Aouizerat[1]

[1]University of California San Francisco, San Francisco, CA, US; [2]John Stroger (formerly Cook County) Hospital, Chicago, IL, US; [3]State University of New York Downstate Medical Center, Brooklyn, NY, US; [4]Montefiore Medical Center, University Hospital for Albert Einstein College of Medicine, Bronx, NY, US; [5]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [6]Georgetown University, Washington, DC, US

517 Pharmacogenomics of Plasma Tenofovir Clearance and Change in Creatinine Clearance

Valentine Wanga[1]; Charles Venuto[2]; Gene D. Morse[3]; Edward A. Acosta[5]; Eric Daar[4]; David W. Haas[1]; Chun Li[1]; Bryan E. Shepherd[1]

[1]Vanderbilt University School of Medicine, Nashville, TN, US; [2]University of Rochester Medical Center, Rochester, NY, US; [3]State University of New York at Buffalo, Buffalo, NY, US; [4]Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA, US; [5]University of Alabama at Birmingham, Birmingham, AL, US

518 Variant ITPA Phenotypes Are Associated With Increased Ribavirin Triphosphate Levels

Leah C. Jimmerson[1]; Thomas J. Urban[2]; Eric Meissner[3]; Ariel Hodara[1]; Jacob A. Langness[4]; Christina Aquilante[1]; Aimee Truesdale[5]; Fafa Baouchi-Mokrane[5]; Michelle Ray[1]; Jennifer J. Kiser[1]

[1]University of Colorado, Aurora, CO, US; [2]University of North Carolina, Chapel Hill, NC, US; [3]NIAID, NIH, Bethesda, MD, US; [4]University of Colorado Health, Aurora, CO, US; [5]Denver Health and Hospital Authority, Denver, CO, US

Session P-H3 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Drug-Drug Interactions

519 Interactions of Antiretroviral Drugs With the SLC22A1 (OCT1) Drug Transporter

Darren M. Moss; Neill Liptrott; Marco Siccardi; Andrew Owen

University of Liverpool, Liverpool, United Kingdom

520 EFV but Not ATV/r Significantly Reduces Atovaquone Concentrations in HIV+ Subjects

Monica M. Calderon[4]; Joseph A. Kovacs[2]; Alice K. Pau[2]; Maryellen McManus[2]; Raul Alfaro[1]; Parag Kumar[1]; Scott R. Penzak[3]

[1]National Institutes of Health (NIH), Bethesda, MD, US; [2]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD, US; [3]University of North Texas System College of Pharmacy, Forth Worth, TX, US; [4]US Food and Drug Administration (FDA), Silver Spring, MD, US

521 The Effect of Single and Multiple Dose Rifampin on the Pharmacokinetics of Doravirine

Ka Lai Yee[3]; Sauzanne G. Khalilieh[2]; Rachael Liu[3]; Rosa Sanchez[3]; Matt S. Anderson[4]; Candice Smith-Bradley[5]; Joan Butterton[6]; Timothy Judge[1]; Helen Manthos[1]; John Brejda[1]

[1]Celerion, Lincoln, NE, US; [2]Merck and Co, Inc, Kenilworth, NJ, US; [3]Merck and Co., Inc., West Point, PA, US; [4]Merck and Co, Inc, Rahway, NJ, US; [5]Merck and Co, Inc, Upper Gwynedd, PA, US; [6]Merck and Co, Inc, Boston, MA, US

522 Drug-Drug Interaction Between HCV Inhibitors Grazoprevir/Elbasvir With Dolutegravir

Wendy W. Yeh[1]; Ted Marenco[2]; Hwa-Ping Feng[1]; Zifang Guo[1]; Daria Stypinski[2]; Lisa Ross[3]; Ivy H. Song[4]; Patricia Jumes[1]; Barbara Cook[2]; Joan R. Butterton[1]

[1]Merck & Co, Inc, Boston, MA, US; [2]Celerion, Lincoln, NE, US; [3]ViiV Healthcare, Research Triangle Park, NC, US; [4]GlaxoSmithKline, Research Triangle Park, NC, US

523 HIV-1 Attachment Inhibitor Prodrug BMS-663068: Interactions with DRV/r and/or ETR

Ishani Savant Landry; Xiaolu Tao; Jeffrey Anderson; Michael Hesney; Michele Stonier; Susan Lubin; Jian Wang; George J. Hanna; David W. Boulton

Bristol-Myers Squibb, Princeton, NJ, US

THURSDAY, FEBRUARY 26, 2015

Session P-H4 Poster Session **Poster Hall**

2:30 pm – 4:00 pm

Pharmacokinetics in Compartments and Reservoirs and of Novel Formulations

524 Local and Systemic Pharmacokinetic Profile of Dapivirine Vaginal Ring-004 When Used Continuously Over Various Periods up to Twelve Weeks

Annalene M. Nel[1]; Wouter Haazen[2]; Marisa Russell[1]; Jeremy P. Nuttall[3]; Neliette Van Niekerk[1]; Nicoline Treijtel[4]

[1]International Partnership for Microbicides, Paarl, South Africa; [2]SGS Life Science Services, Antwerp, Belgium; [3]International Partnership for Microbicides, Silver Spring, MD, US; [4]Kinesis Pharma BV, Breda, Netherlands

525 Steady-state TDF/FTC in Genital, Rectal, and Blood Compartments in Males vs Females

Sharon M. Seifert[1]; Amie L. Meditz[2]; Jose R. Castillo-Mancilla[3]; Edward M. Gardner[3]; Brandon Klein[1]; Becky Kerr[1]; L. Anthony Guida[1]; Jia-Hua Zheng[1]; Lane R. Bushman[1]; Peter L. Anderson[1]

[1]University of Colorado, Aurora, CO, US; [2]Boulder Community Hospital, Boulder, CO, US; [3]University of Colorado School of Medicine, Aurora, CO, US

526 Effects of Tenofovir/Emtricitabine on Endogenous Deoxyribonucleotide Pools In Vivo

Xinhui Chen[1]; Kevin McAllister[1]; Jia-Hua Zheng[1]; Jose R. Castillo-Mancilla[1]; Amie Meditz[2]; Brandon Klein[1]; Sharon M. Seifert[1]; Lane Bushman[1]; Peter L. Anderson[1]

[1]University of Colorado Anschutz Medical Campus, Aurora, CO, US; [2]Beacon Center of Infectious Diseases, Boulder, CO, US

527 Higher Cell Accumulation and Antiviral Activity of Lopinavir/Ritonavir Nanoparticles

Philip Martin[1]; Tom O. McDonald[2]; Marco Giardiello[2]; Steven P. Rannard[2]; Andrew Owen[1]

[1]University of Liverpool, Liverpool, United Kingdom; [2]University of Liverpool, Liverpool, United Kingdom

528 HIV reservoir targeted antiretroviral nanofabrication facilitates viral clearance

Pavan Puligujja[1]; JoEllyn McMillan[1]; Shantanu Balkundi[2]; Prasanta K. Dash[1]; James Hilaire[1]; Santhi Gorantla[1]; Larisa Poluektova[1]; Xin-Ming Liu[1]; Howard Gendelman[1]

[1]University of Nebraska Medical Center, Omaha, NE, US; [2]Kansas University Innovation and Collaboration, Lawrence, KS, US

529 The Macrophage Proteome Defines the Long Acting Antiretroviral Therapy Cell Depot

Dongwei Guo; Mariluz Araínga; Jayme Horning; Pawel Ciborowski; Xin-Ming Liu; JoEllyn McMillan; Howard Gendelman

University of Nebraska Medical Center, Omaha, NE, US

530 Primary CD4 Subsets Are Similarly Loaded by Tenofovir Alafenamide (TAF)

Christian R. Frey; Yang Liu; Darius Babusis; Adam Palazzo; Adrian S. Ray; Michael D. Miller; Kathryn M. Kitrinos; **Christian Callebaut**

Gilead Sciences, Inc., Foster City, CA, US

Session P-H5 Poster Session **Poster Hall**

2:30 pm – 4:00 pm

New Technologies in Assessing Drug Interactions and Systemic and Intracellular Pharmacology

531 Pharmacokinetic Interactions Between Antidiabetics and Efavirenz Using PBPK Modeling

Catia Marzolini[1]; Rajith Rajoli[2]; Luigia Elzi[1]; Manuel Battegay[1]; David Back[2]; Marco Siccardi[2]

[1]University Hospital Basel, Basel, Switzerland; [2]Institute of Translational Medicine, University of Liverpool, Liverpool, United Kingdom

532 In Silico Simulation of Interaction Between Rifampicin and Boosted Darunavir

Marco Siccardi; Owain Roberts; Rajith Rajoli; Laura Dickinson; Saye Khoo; Andrew Owen; David Back

University of Liverpool, Liverpool, United Kingdom

533 Pharmacogenetics of Pregnancy-Induced Changes in Efavirenz Pharmacokinetics

Adeniyi Olagunju[1]; Oluseye Bolaji[2]; Alieu Amara[1]; Laura Else[1]; Ogechi Okafor[3]; Ebunoluwa Adejuyigbe[2]; Oyigboja Johnson[4]; David Back[1]; Saye Khoo[1]; Andrew Owen[1]

[1]University of Liverpool, Liverpool, United Kingdom; [2]Obafemi Awolowo University, Ile-Ife, Nigeria; [3]Bishop Murray Medical Centre, Makurdi, Nigeria; [4]Catholic Caritas Foundation of Nigeria, Makurdi, Nigeria

534 Antiretroviral Drug Transporters and Metabolic Enzymes in Human Testicular Tissue

Billy Huang[1]; Md. Tozammel Hoque[1]; Mohammad-Ali Jenabian[3]; Kishanda Vyboh[2]; Nancy Sheehan[2]; Pierre Brassard[4]; Maud Bélanger[4]; Nicolas Chomont[5]; Jean-Pierre Routy[2]; Reina Bendayan[1]

[1]University of Toronto, Toronto, Canada; [2]McGill University, Montréal, Canada; [3]Université du Québec à Montréal, Montréal, Canada; [4]Metropolitan Centre of Plastic Surgery, Montréal, Canada; [5]Vaccine and Gene Therapy Institute of Florida, Port St Lucie, FL, US

535 Imaging the Spatial Distribution of Efavirenz in Intact HIV Tissue Reservoirs

Elias P. Rosen[1]; Corbin G. Thompson[2]; Mark T. Bokhart[1]; Craig Sykes[2]; Yuri Fedoriw[2]; Paul Luciw[3]; David C. Muddiman[1]; Angela D.M. Kashuba[2]

[1]North Carolina State University, Raleigh, NC, US; [2]University of North Carolina, Chapel Hill, NC, US; [3]University of California Davis, Davis, CA, US

WEDNESDAY, FEBRUARY 25, 2015

Session P-I1 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Drug Development

536 Inhibition of HIV-1 Replication by a Novel Acylguanidine-Based Molecule

Philip Mwimanzi[1]; Ian Tietjen[2]; Aniqa Shahid[1]; Scott C. Miller[2]; David Fedida[2]; Zabrina L. Brumme[1]; Mark Brockman[1]

[1]Simon Fraser University, Burnaby, Canada; [2]University of British Columbia, Vancouver, Canada

537 4′-Ethynyl-2-Fluoro-2′-Deoxyadenosine (EFdA) Has an Extremely High Genetic Barrier, Persistently Exerting Highly Potent Activity Against a Variety of HIV-1 Isolates Including EFdA-Selected HIV-1 Variants

Kenji Maeda[1]; Yuki Takamatsu[1]; Satoru Kohgo[2]; Nicole S. Delino[1]; Simon B. Chang[1]; Kazuhiro Haraguchi[3]; Hiroaki Mitsuya[1]

[1]National Institutes of Health (NIH), Bethesda, MD, US; [2]National Center for Global Health and Medicine, Tokyo, Japan; [3]Nihon Pharmaceutical University, Saitama, Japan

538 GSK2838232, a Second Generation HIV-1 Maturation Inhibitor With an Optimized Virology Profile

Jerry Jeffrey[1]; Ping Wang[1]; Charlene McDanal[1]; Pauline J. Shipper[2]; Kevin Brown[1]; Cristin Galardi[1]; Jun Tang[1]; Monique Nijhuis[2]; Brian Johns[1]

[1]GlaxoSmithKline, Research Triangle Park, NC, US; [2]University of Utrecht, Utrecht, Netherlands

539 Maturation Inhibitor Mechanistic Studies - Differential Inhibition of Gag Polymorphs

Zeyu Lin[1]; Joseph Cantone[1]; Tricia Protack[1]; Dieter Drexler[1]; Beata Nowicka-Sans[1]; Yuan Tian[3]; Zheng Liu[1]; Mark Krystal[1]; Alicia Regueiro-Ren[1]; **Ira B. Dicker**[1]

[1]Bristol-Myers Squibb Co, Wallingford, CT, US; [2]Bristol-Myers Squibb Co, Wallingford, CT, US; [3]Bristol-Myers Squibb Co, Princeton, NJ, US; [4]Bristol-Myers Squibb Co, Wallingford, CT, US

540 Late-Stage Integrase-LEDGF Inhibitors Mode of Action and Acquisition of Resistance

Richard Benarous[1]; Erwann Le Rouzic[1]; Nikki van Bel[2]; Yme Van der Velden[2]; Damien Bonnard[1]; Atze Das[2]; Celine Amadori[1]; Alessia Zamborlini[4]; Stephane Emiliani[3]; Ben Berkhout[2]

[1]Biodim Mutabilis, Romainville, France; [2]Academic Medical centre, Amsterdam, Netherlands; [3]Inserm CNRS, Paris, France; [4]U944 UMR7212, Inserm CNRS, Paris, France

541 BMS-986001: A Promising Candidate for HIV-2 Treatment

Robert A. Smith[1]; Dana Raugi[1]; Kate Parker[1]; Mariah Oakes[1]; Papa Salif Sow[2]; Selly Ba[2]; Moussa Seydi[2]; Geoffrey S. Gottlieb[1]

On behalf of the University of Washington-Dakar HIV-2 Study Group

[1]University of Washington, Seattle, WA, US; [2]CHNU de Fann, Dakar, Senegal

542 Dual Loaded Sustained Release Core-Shell Nanoparticles for Anti-HIV Therapy

Hilliard L. Kutscher[1]; Jessica L. Reynolds[1]; Faithful Makita[2]; Sara DiTursi[1]; Jacob Milling[1]; Jesse Hanchett[1]; Charles C. Maponga[2]; Paras N. Prasad[1]; Gene D. Morse[1]

[1]University at Buffalo, Buffalo, NY, US; [2]University of Zimbabwe, College of Health Sciences, Harare, Zimbabwe

543 Chemical Facilitated Endosomal Storage of Long-Acting Antiretroviral Nanoparticles

Dongwei Guo; **Prasanta K. Dash**; Gang Zhang; Mariluz Arainga; Jaclyn Knibbe; JoEllyn McMillan; Larisa Poluektova; Harris Gelbard; Santhi Gorantla; Howard Gendelman

University of Nebraska Medical Center, Omaha, NE, US

TUESDAY, FEBRUARY 24, 2015

Session P-J1 Poster Session — Poster Hall

2:30 pm – 4:00 pm

ART: Recent Perspectives

544 24-Weeks Virologic Efficacy of Fozivudine in ART-Naïve Patients From Africa

Arne Kroidl[1]; Tessa Lennemann[1]; Frederic Ello[2]; Jimson Mgaya[3]; Raoul Moh[2]; Lucas Maganga[3]; Serge P. Eholié[2]; Pierre-Marie Girard[4]; Friedrich von Massow[5]; Christine Danel[6]

[1]Medical Center of the University of Munich (LMU), Munich, Germany; [2]CHU de Treichville, Abidjan, Côte d'Ivoire; [3]NIMR–Mbeya Medical Research Center, Mbeya, United Republic of Tanzania; [4]University Hospital Saint-Antoine, Paris, France; [5]Institute for Life Sciences and Environment GmbH, Heidelberg, Germany; [6]Programme PAC-CI, ANRS, Abidjan, Côte d'Ivoire

545 Attachment Inhibitor Prodrug BMS–663068 in ARV-Experienced Subjects: Week 48 Analysis

Melanie Thompson[1]; Jay Lalezari[2]; Richard Kaplan[3]; Yvette Pinedo[4]; Otto Sussman Pena[5]; Pedro Cahn[6]; David A. Stock[7]; Samit R. Joshi[7]; George J. Hanna[8]; Max Lataillade[7]

[1]AIDS Research Consortium of Atlanta, Atlanta, GA, US; [2]Quest Clinical Research, San Francisco, CA, US; [3]Desmond Tutu HIV Foundation, Cape Town, South Africa; [4]Asociacion Civil Via Libre, Lima, Peru; [5]Asistencia Cientifica de Alta Complejidad SAS, Bogotá, Colombia; [6]Fundacion Huesped, Buenos Aires, Argentina; [7]Bristol-Myers Squibb, Wallingford, CT, US; [8]Bristol-Myers Squibb, Princeton, NJ, US

546 Delay in Antiretroviral Therapy Is Not Associated With Increased Virologic Failure

Ashita S. Batavia[1]; Patrice Severe[2]; Marc Antoine Jean Juste[2]; Rode Secours[2]; Daphne C. Bernard[2]; William J. Pape[2]; Daniel Fitzgerald[1]

[1]Weill Cornell Medical College, New York, NY, US; [2]GHESKIO Center, Port-au-Prince, Haiti

547 Effects of Quadruple First-Line ART on Mucosal Immunity

Sergio Serrano-Villar[1]; Talía Sainz[2]; Surinder Mann[3]; Zhong-Min Ma[3]; Christopher Miller[3]; Netanya S. Utay[4]; Basile Siewe[5]; Tae Wook-Chun[6]; Paolo Troia-Cancio[3]; David Asmuth[3]

[1]University Hospital Ramón y Cajal, Madrid, Spain; [2]University Hospital Gregorio Marañón, Madrid, Spain; [3]University of California Davis, Sacramento, CA, US; [4]University of Texas, Galveston, TX, US; [5]Rush University Medical Center, Chicago, IL, US; [6]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD, US

548 Maraviroc-Dependent Pharmacologic Effects on Viral Decay and Immune Recovery in GALT

Corbin Thompson[1]; Tae Wook Chun[2]; Craig Sykes[1]; Zhing-Min Ma[4]; Christopher Miller[4]; Surinder Mann[3]; Richard Pollard[3]; Angela Kashuba[1]; David Asmuth[3]

[1]University of North Carolina at Chapel Hill, Chapel Hill, NC, US; [2]Division of AIDS, NIAID, NIH, Bethesda, MD, US; [3]University of California Davis Medical Center, Davis, CA, US; [4]University of California Davis, Davis, CA, US

549 Maraviroc Induces HIV Production in RCT and In Vitro, Potentially via the NFkB Pathway

Jori Symons[1]; Ward de Spiegelaere[2]; Annemarie Wensing[1]; Julia Drylewicz[3]; Ananja Middel[4]; Andy I. Hoepelman[4]; Kiki Tesselaar[3]; Linos Vandekerckhove[2]; Steven F. van Lelyveld[4]; **Monique Nijhuis**[1]

[1]University Medical Center Utrecht, Utrecht, Netherlands; [2]Ghent University, Ghent, Belgium; [3]University Medical Centre Utrecht, Utrecht, Netherlands; [4]University Medical Centre Utrecht, Utrecht, Netherlands

550 Consistency of Dolutegravir Treatment Difference in HIV+ Treatment Naives at Week 96

Catherine M. Granier[1]; **Robert Cuffe**[2]; Louise Martin-Carpenter[3]; Kimberly Y. Smith[3]; Clare Brennan[4]; Keith Pappa[4]; Brian Wynne[4]; Steve Almond[5]; Naomi Givens[1]; Michael Aboud[2]

[1]GlaxoSmithKline, Uxbridge, United Kingdom; [2]ViiV Healthcare, London, United Kingdom; [3]ViiV Healthcare, Research Triangle Park, NC, US; [4]GlaxoSmithKline, Research Triangle Park, NC, US; [5]GlaxoSmithKline, Mississauga, Canada

551 Predictors of HIV RNA Suppression on Darunavir/Ritonavir Monotherapy in the MONET and PROTEA Trials

Diego Ripamonti[2]; Ralph DeMasi[3]; **Andrew M. Hill**[1]; Ceyhun Bicer[4]; Christiane Moecklinghoff[5]

[1]Chelsea and Westminster Hospital, London, United Kingdom; [2]A.O. Papa Giovanni XXIII, Bergamo, Italy; [3]Janssen Pharmaceuticals, Inc., Titusville, NJ, US; [4]Janssen Pharmaceuticals, Inc., Beerse, Belgium; [5]Janssen Pharmaceuticals, Inc., Neuss, Germany

552 Second-Line Treatment in Sub-Saharan Africa: Week 144 Follow-up of the EARNEST Trial

James G. Hakim[1]; Jennifer Thompson[2]; Cissy M. Kityo[3]; Sarah Walker[2]; Joep van Oosterhout[4]; Anne Hoppe[2]; Andrew D. Kambugu[5]; Peter Mugyenyi[3]; Nicholas Paton[6]
On behalf of the EARNEST Trial Team

[1]University of Zimbabwe, College of Health Sciences, Harare, Zimbabwe; [2]University College London, London, United Kingdom; [3]Joint Clinical Research Centre, Kampala, Uganda; [4]Dignitas, Zomba, Zomba, Malawi; [5]Infectious Disease Institute, Kampala, Uganda; [6]National University of Singapore, Singapore, Singapore; [7]MRC Clinical Trials Unit at University College London, London, United Kingdom

553 Withdrawing Inactive NRTIs in Subjects With Suppressed Viremia: A Randomized Trial

Josep M. Llibre[1]; Hortensia Alvarez[8]; Antonio Antela[2]; Jessica Toro[1]; Juan González-Moreno[3]; M Jesús Perez-Elias[4]; Arkaitz Imaz[5]; Mar Masià[6]; Manel Crespo[7]; Bonaventura Clotet[1]

[1]Univ Hosp Germans Trias, Badalona, Spain; [2]Hospital Clínico Universitario, Santiago de Compostela, Spain; [3]Hospital Son Llàtzer, Mallorca, Spain; [4]Hospital Ramón y Cajal, IRYCIS, Madrid, Spain; [5]Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, Spain; [6]Hospital Universitario de Elche, Elche, Spain; [7]Hospital Universitari Vell d'Hebró, Barcelona, Spain; [8]Complejo Universitario de Ferrol, A Coruña, Spain

554LB Cabotegravir and Rilpivirine As 2-Drug Oral Maintenance Therapy: LATTE W96 Results

David A. Margolis[1]; Cynthia C. Brinson[2]; Graham H. Smith[3]; Jerome de Vente[4]; Debbie P. Hagins[5]; Sandy K. Griffith[1]; Marty H. St. Clair[1]; Kimberly Y. Smith[6]; Peter E. Williams[7]; William R. Spreen[1]

[1]GlaxoSmithKline, Durham, NC, US; [2]Central Texas Clinical Research, Austin, TX, US; [3]Maple Leaf Medical Clinic, Toronto, Canada; [4]Living Hope Foundation, Long Beach, CA, US; [5]Chatham County Health Department, Savannah, GA, US; [6]ViiV Healthcare, Durham, NC, US; [7]Janssen Pharmaceuticals, Inc, Beerse, Belgium

Session P-K1 Poster Session — Poster Hall

2:30 pm – 4:00 pm

ART: Adherence, Adherence, Adherence

555 Self-Reported Versus Blood-Tested ART Intake to Estimate ART Coverage in South Africa

Helena Huerga[1]; Gilles Van Cutsem[2]; Lubbe Wiesner[3]; Malika Bouhenia[1]; Jihane Ben Farhat[1]; Emmanuel Fajardo[2]; Ruggero G. Giuliani[2]; David Maman[1]; Thomas Ellman[2]; Jean-François Etard[1]

[1]Epicentre, Paris, France; [2]Médecins Sans Frontières, Cape Town, South Africa; [3]University of Cape Town, Cape Town, South Africa

556 Real-Time Electronic Adherence Monitoring and Risk of Viral Rebound

Jessica E. Haberer[1]; Nicholas Musinguzi[2]; Mark Siedner[1]; Yap Boum[3]; Peter W. Hunt[4]; Jeffrey Martin[4]; David R. Bangsberg[1]

[1]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [2]Mbarara University of Science and Technology, Mbarara, Uganda; [3]Médecins Sans Frontières, Mbarara, Uganda; [4]University of California San Francisco, San Francisco, CA, US

557 Determinants of Adherence to Antiretroviral Therapy Differ Between Africa and Asia

Rimke Bijker[1]; Awachana Jiamsakul[2]; Margaret Siwale[3]; Sasisopin Kiertiburanakul[4]; Cissy M. Kityo[5]; Praphan Phanuphak[6]; Tobias F. Rinke de Wit[1]; Oon Tek Ng[7]; Raph L. Hamers[1]; PASER-TASER Cohort Collaboration[1]
PASER-TASER Cohort Collaboration

[1]Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands; [2]The Kirby Institute, Sydney, Australia; [3]Lusaka Trust Hospital, Lusaka, Zambia; [4]Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; [5]Joint Clinical Research Centre, Kampala, Uganda; [6]HIV-NAT/Thai Red Cross AIDS Research Centre, Bangkok, Thailand; [7]Tan Tock Seng Hospital, Novena, Singapore

558 Retention on Antiretroviral Therapy by Sex and Pregnancy Status in a Large Cohort of HIV-Infected Patients in Rural Nigeria

Usman I. Gebi[2]; Meridith Blevins[1]; Mukhtar Y. Muhammad[2]; C. William Wester[1]; Muktar H. Aliyu[1]

[1]Vanderbilt University, Nashville, TN, US; [2]Friends for Global Health Initiative Nigeria, Abuja, Nigeria

559 Randomised Controlled Trial of Text-Message Dosing Reminders in Patients Starting ART

Catherine Orrell[1]; Karen Cohen[1]; Katya Mauff[1]; David R. Bangsberg[2]; Gary Maartens[1]; Robin Wood[1]

[1]University of Cape Town, Cape Town, South Africa; [2]Harvard Medical School, Boston, MA, US

560 Socioeconomic Factors and Virological Rebound: A Prospective UK Cohort Study

Lisa S. Burch[1]; Colette Smith[1]; Jane Anderson[3]; Lorraine Sherr[1]; Alison Rodger[1]; Richard Gilson[1]; Jonathan Elford[2]; Andrew N. Phillips[1]; Margaret Johnson[4]; Fiona Lampe[1]
ASTRA (Antiretrovirals, Sexual Transmission Risk and Attitudes)

[1]University College London, London, United Kingdom; [2]City University London, London, United Kingdom; [3]Homerton University Hospital NHS Foundation Trust, London, United Kingdom; [4]Royal Free London NHS Foundation Trust, London, United Kingdom

Session P-K2 Poster Session — Poster Hall

2:30 pm – 4:00 pm

ART: Monitoring and Biomarkers

561 New Marker of Standard-of-ART Care: Percentage of Time on cART With Suppressed HIV-RNA

Kamilla G. Laut[1]; Leah C. Shepherd[4]; Court Pedersen[2]; Jürgen Rockstroh[3]; Helen Sambatakou[5]; Dzmitry Paduta[6]; Jens D. Lundgren[1]; Amanda Mocroft[4]; Ole Kirk[1]; EuroSIDA in EuroCoord[1]
on behalf of EuroSIDA in EuroCoord

[1]Rigshospitalet, University of Copenhagen, Copenhagen, Denmark; [2]Odense University Hospital, Odense, Denmark; [3]University Hospital Bonn, Bonn, Germany; [4]University College London, London, United Kingdom; [5]Hippokration General Hospital, University of Athens, Athens, Greece; [6]Gomel Regional Centre for Hygiene, Gomel, Belarus

562 Viremia Copy Years and Its Impact on Risk of Clinical Progression According to Shape

Alessandro Cozzi-Lepri[1]; Antonella Cingolani[2]; Andrea Antinori[3]; Andrea De Luca[4]; Cristina Mussini[5]; Stefano Rusconi[6]; Carmela Pinnetti[3]; Massimo Galli[6]; Antonella Castagna[8]; Antonella d'Arminio Monforte[7]

[1]University College London, London, United Kingdom; [2]Sacro Cuore University, Roma, Italy; [3]INMI Spallanzani, Roma, Italy; [4]University of Siena, Siena, Italy; [5]University of Modena, Modena, Italy; [6]Luigi Sacco University Hospital, Milano, Italy; [7]S. Paolo Hospital, Milano, Italy; [8]San Raffaele Scientific Institute, Milano, Italy

563 Monitoring and Switching of Antiretroviral Therapy in Sub-Saharan Africa

Andreas D. Haas[1]; Olivia Keiser[1]; François Dabis[2]; Mary-Ann Davies[3]; Rosalind M. Parkes-Ratanshi[4]; Steven J. Reynolds[5]; Kara Wools-Kaloustian[6]; Gilles Wandeler[1]; Matthias Egger[1]
IeDEA East, West and Southern Africa

[1]Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland; [2]Université Bordeaux, Bordeaux, France; [3]University of Cape Town, Cape Town, South Africa; [4]Makerere University College of Health Sciences, Makerere, Uganda; [5]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD, US; [6]Indiana University, Indianapolis, IN, US

564 Virological Factors Associated With Outcome of Dual MVC/RAL Therapy (ANRS-157 Trial)

Cathia Soulie[1]; Lambert Assoumou[2]; Melanie Darty[3]; Christophe Rodriguez[3]; Gilles Peytavin[4]; Marc-Antoine Valantin[5]; Dominique Costagliola[2]; Christine Katlama[5]; Vincent Calvez[1]; Anne-Genevieve Marcelin[1]

[1]Hôpital Pitié Salpêtrière, Paris, France; [2]INSERM/UPMC, Paris, France; [3]APHP Mondor, Creteil, France; [4]APHP Bichat, Paris, France; [5]Hôpital Saint-Louis, APHP, Université Paris Diderot, Paris, France

565 D-dimer Doesn't Return to Pre-HIV Levels After Therapy and Is Linked With HANA Events

Matthew S. Freiberg[2]; Ionut Bebu[4]; Russell Tracy[3]; Jason F. Okulicz[1]; Anuradha Ganesan[1]; Adam Armstrong[5]; Thomas O'Bryan[1]; **Brian K. Agan**[1]
IDCRP HIV Working Group

[1]Uniformed Services University of the Health Sciences, North Bethesda, MD, US; [2]Vanderbilt University Medical Center, Nashville, TN, US; [3]University of Vermont College of Medicine, Burlington, VT, US; [4]The George Washington University, Rockville, MD, US; [5]US Naval Medical Research Unit No. 6 Peru, Lima, Peru

566 Virological Responses to Lamivudine and Emtricitabine in the Nationwide ATHENA Cohort

Casper Rokx[1]; Azzania Fibriani[1]; David A. van de Vijver[1]; Annelies Verbon[1]; Martin Schutten[1]; Luuk Gras[2]; Bart J. Rijnders[1]
On behalf of the Dutch HIV Monitoring Foundation

[1]Erasmus University Medical Center, Rotterdam, Netherlands; [2]Academic Medical Center University of Amsterdam, Amsterdam, Netherlands

567 Prevalence and Risk Factors of Multiple Micronutrient Deficiencies Pre- and Post-ART

Rupak Shivakoti[1]; Parul Christian[2]; Nikhil Gupte[1]; Cecilia Kanyama[3]; Sima Berendes[4]; Javier Lama[5]; Richard Semba[1]; Thomas Campbell[6]; Amita Gupta[1]
NWCS 319 and PEARLS Study Team

[1]Johns Hopkins University School of Medicine, Baltimore, MD, US; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [3]University of North Carolina Project–Malawi, Lilongwe, Malawi; [4]Malawi College of Medicine-Johns Hopkins University Research Project, Blantyre, Malawi; [5]Asociacion Civil Impacta Salud y Educacion, Lima, Peru; [6]University of Colorado School of Medicine, Aurora, CO, US

568 Detection of HIV RNA and DNA in Anal Swabs of HIV Infected Men Having Sex With Men

Julian Storim[1]; **Jens Verheyen**[1]; Eva Wolff[1]; Lewin Eisele[1]; Jeremias Wohlschläger[2]; Peter-Michael Rath[1]; Evelyn Heintschel von Heinegg[1]; Dirk Schadendorf[1]; Stefan Esser[1]

[1]University Hospital Essen, University Duisburg-Essen, Essen, Germany; [2]University Hospital Essen, Essen, Germany

WEDNESDAY, FEBRUARY 25, 2015

Session P-K3 Poster Session **Poster Hall**
2:30 pm – 4:00 pm

ART: Immunologic Response—The Good and The Bad

569 Reference Curves for CD4 Response to Antiretroviral Treatment in HIV-1–Infected Naïve Patients

Rodolphe Thiebaut
On behalf of the Standard Reference Distribution of CD4 Working Group in COHERE in EuroCoord

Bordeaux University, Bordeaux, France

570 Comparing Immunological Failure Definitions, Using Tanzanian National HIV Data

Fiona Vanobberghen[1]; Bonita K. Kilama[2]; Alison Wringe[1]; Angela Ramadhani[2]; Basia Zaba[1]; Donan Mmbando[3]; Jim Todd[1]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom; [2]National AIDS Control Program, Dar es Salaam, United Republic of Tanzania; [3]Ministry of Health & Social Welfare, Dar es Salaam, United Republic of Tanzania

571 Delaying Second-Line Therapy After First-Line Failure: Moderating Effect of CD4 Count

Julia K. Rohr[1]; Prudence Ive[2]; Rebecca H. Berhanu[3]; Kate Shearer[2]; Mhairi Maskew[2]; Lawrence Long[2]; Ian Sanne[2]; Matthew P. Fox[1]

[1]Boston University School of Public Health, Boston, MA, US; [2]University of Witswatersrand, Johannesburg, South Africa; [3]Right to Care, Johannesburg, South Africa

572 Rapid Progression Hinders the Recovery of CD4 + T Cells Following Initiation of cART

Inma Jarrin
On behalf of the CASCADE Collaboration within EUROCOORD

Instituto de Salud Carlos III, Madrid, Spain

573 Increase in CD4 Counts at Presentation to ART Care Among Urban HIV Clinics in Uganda

ELIZABETH K. NALINTYA[1]; Agnes N. Kiragga[1]; Edison Katunguka[2]; Henry W. Nabeta[1]; Joanita Kigozi[1]; Yukari Manabe[4]; David R. Boulware[2]; Jon Kaplan[3]; David B. Meya[1]

[1]Infectious Diseases Institute, Kampala Uganda, Kampala, Uganda; [2]University of Minnesota, Minneapolis, MN, US; [3]CDC Center for Global Health, Division of Global AIDS/HIV, Atlanta, GA, US; [4]Johns Hopkins University, Baltimore, MD, US

574 Implications of Poor CD4 Recovery During HIV Suppressive ART in Sub-Saharan Africa

Marieke E. de Pundert[1]; Tamara Sonia Boender[1]; Raph L. Hamers[1]; Kim Sigaloff[1]; Cissy M. Kityo[2]; Alani S. Akanmu[3]; Maureen Wellington[4]; Tobias F. Rinke de Wit[1]; Pascale Ondoa[1]
Pan African Studies to Evaluate Resistance (PASER) studygroup

[1]Amsterdam Institute for Global Health and Development, Brasschaat, Belgium; [2]Joint Clinical Research Centre Kampala, Kampala, Uganda; [3]Lagos University Teaching Hospital, Lagos, Nigeria; [4]Newlands Clinic, Harare, Zimbabwe

575 Better CD4/CD8 Restoration in First-Line HIV-Infected CMV-Seronegative Patients

Isabelle Poizot-Martin[1]; Clotilde Allavena[2]; Claudine Duvivier[3]; Carla E. Cano[1]; Francine Guillouet de Salvador[4]; David Rey[5]; Lise Cuzin[6]; Antoine Cheret[7]; Bruno Hoen[8]
On behalf of the Dat'AIDS Group

[1]Aix-Marseille Univ, APHM Hôpital Sainte-Marguerite, Marseille, France; [2]CHU Hotel Dieu, Nantes, France; [3]APHP–Hopital Necker–Université Paris Descartes–IHU Imagine, Paris, France; [4]CHU Archet 1, Nice, France; [5]Hôpitaux Universitaires Strasbourg, Strasbourg, France; [6]Regional Coordination for HIV, Toulouse, France; [7]Hospital Tourcoing, Tourcoing, France; [8]University Medical Center of Guadeloupe, Guadeloupe, France; [9]The Dat'AIDS Group, Nice, France

576 CD4 Response in Treatment-Naïve HIV-2–Infected Patients: The IeDEA West Africa Cohort

Eric Balestre[1]; Koumavi K. Ekouevi[2]; Boris Tchounga[2]; Serge P. Eholié[3]; Eugène Messou[4]; Adrien Sawadogo[5]; Rodolphe Thiebaut[1]; Margaret T. May[6]; Jonathan A. Sterne[6]; François Dabis[1]

[1]Univ Bordeaux, ISPED, Centre Inserm U897-Epidemiologie-Biostatistique, Bordeaux, France; [2]Programme PAC-CI, Centre Hospitalier Universitaire de Treichville, Abidjan, Côte d'Ivoire; [3]Service de Maladies Infectieuses et Tropicales, Centre Hospitalier Universitaire de Treichville, Abidjan, Côte d'Ivoire; [4]Centre de Prise en Charge de Recherche et de Formation, Hôpital Yopougon Attié, Abidjan, Côte d'Ivoire; [5]Institut Supérieur des Sciences de la Santé, Université Polytechnique de Bobo-Dioulasso, Bobo-Dioulasso, Burkina Faso; [6]School of Social and Community Medicine, Bristol University, Bristol, United Kingdom

Session P-K4 Poster Session **Poster Hall**
2:30 pm – 4:00 pm

ART: Mortality

577 Mortality and Retention After 12 Months in a Cohort of Patients Initiated With the New WHO Recommendations in Uganda

John Ssali; Juan Gonzalez Perez; Jonathan Ikapule; Lydia Buzaalirwa; Kate Ssamula; Augustine Lubanga; Sulaiman Kawooya; Monday Busuulwa; Penninah Lutung Amor; **Michael Wohlfeiler**

AIDS Healthcare Foundation, Kampala, Uganda

578 Effect of ART on Mortality Generalized to Newly HIV-Diagnosed Persons in the USA

Catherine R. Lesko[1]; Stephen R. Cole[1]; H. Irene Hall[3]; Michael J. Mugavero[2]

[1]University of North Carolina, Chapel Hill, NC, US; [2]University of Alabama at Birmingham, Birmingham, AL, US; [3]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US

579 Association of CD4:CD8 With Cause-Specific Mortality in Patients on Long-Term ART

Margaret T. May[1]; Adam Trickey[1]; Dominique Costagliola[6]; Peter Reiss[4]; Santiago Moreno[5]; John Gill[3]; Colette Smith[2]; Suzanne M. Ingle[1]; Jonathan A. Sterne[1]
On behalf of the Antiretroviral Therapy Cohort Collaboration (ART-CC)

[1]University of Bristol, Bristol, United Kingdom; [2]University College London, London, United Kingdom; [3]University of Calgary, Calgary, Canada; [4]Academic Medical Center University of Amsterdam, Amsterdam, Netherlands; [5]Hospital Ramón y Cajal, Madrid, Spain; [6]UMR S 1136, Inserm et Sorbonne Universités, Université Pierre et Marie Curie, Paris, France

580 Outcomes of First ART in Latino Populations in North America and Latin America

Carina T. Cesar[1]; Mark J. Giganti[2]; Bryan E. Shepherd[2]; Richard Moore[3]; Keri N. Althoff[3]; Sonia Napravnik[4]; Angel M. Mayor[5]; Catherine Mc Gowan[2]; Pedro E. Cahn[1]

[1]Fundacion Huesped, Buenos Aires, Argentina; [2]Vanderbilt University, Nashville, TN, US; [3]Johns Hopkins University, Baltimore, MD, US; [4]University of North Carolina, Chapel Hill, NC, US; [5]Retrovirus Research Center, Bayamon, US

581 WITHDRAWN

582 Impact of Specific Antiretroviral Drugs on Non-AIDS Mortality; the D:A:D Study

Camilla I. Hatleberg[1]; Lene Ryom[1]; Andrew N. Phillips[2]; Amanda Mocroft[2]; Peter Reiss[3]; Matthew Law[4]; Rainer Weber[5]; François Dabis[6]; Jens D. Lundgren[1]; Colette Smith[2]
On behalf of the D:A:D Study group

[1]Rigshospitalet, University of Copenhagen, Copenhagen, Denmark; [2]University College London, London, United Kingdom; [3]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands; [4]University of New South Wales, Sydney, Australia; [5]University Hospital Zurich, Zurich, Switzerland; [6]University of Bordeaux, Bordeaux, France

583 HIV-Related Causes of Death in the Era of Antiretroviral Therapy: Analysis of Verbal Autopsy Data

Clara Calvert[1]; Zehang Li[2]; Tyler McCormick[2]; Alison Price[1]; Kobus Herbst[4]; Denna Michael[3]; Estelle McLean[1]; Basia Zaba[1]; Samuel Clark[2]
On behalf of the ALPHA network

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom; [2]University of Washington, Seattle, WA, US; [3]National Institute for Medical Research, Mwanza, United Republic of Tanzania; [4]Africa Centre for Health and Population Studies, Mtubatuba, South Africa

584 Facility-Level Factors Associated With Mortality of Patients on ART: A Retrospective Cohort Study in Kenya, 2007-2012

Emily A. Dansereau[1]; Allen Roberts[1]; Herbert C. Duber[1]; Gregoire Lurton[1]; Brendan DeCenso[2]; Thomas Odeny[1]; Samuel Masters[3]; Roy Burstein[1]; Pamela Njuguna[1]; Emmanuela Gakidou[1]

[1]University of Washington, Seattle, WA, US; [2]RTI International, Raleigh, NC, US; [3]University of North Carolina, Chapel Hill, NC, US

THURSDAY, FEBRUARY 26, 2015

Session P-L1 Poster Session — Poster Hall

2:30 pm – 4:00 pm

HIV Drug Resistance: Mechanisms and Mutations

585 Structural Basis of Inhibition and Resistance Mechanism to EFdA, a Highly Potent NRTI

Zhe Li[1]; Karen Kirby[1]; Bruno Marchand[1]; Michailidis Eleftherios[1]; Eiichi Kodama[2]; Hiroaki Mitsuya[3]; Michael Parniak[4]; Stefan Sarafianos[1]

[1]University of Missouri, Columbia, MO, US; [2]Tohoku University, Sendai, Japan; [3]National Institutes of Health, Division of AIDS, Bethesda, MD, US; [4]University of Pittsburgh, Pittsburgh, PA, US

586 Structural Basis and Distal Effects of Gag Substrate Coevolution in Drug Resistance to HIV-1 Protease

Kuan-Hung Lin; Celia A. Schiffer

University of Massachusetts Medical School, Worcester, MA, US

587 Influence of Codon Pair Usage in the Evolvability of HIV-1

Maria Nevot; Cristina Andrés; Mariona Parera; Glòria Martrus; Miguel Ángel Martínez

IrsiCaixa Institute for AIDS Research, Badalona, Spain

588 Four Amino Acid Changes in HIV-2 Protease Confer Class-Wide PI Susceptibility

Dana N. Raugi[1]; Robert A. Smith[1]; Matthew Coyne[1]; Julia Olson[1]; Kara Parker[1]; Selly Ba[2]; Papa Salif Sow[2]; Moussa Seydi[2]; Geoffrey S. Gottlieb[1]
University of Washington-Dakar HIV-2 Study Group

[1]University of Washington School of Medicine, Seattle, WA, US; [2]Centre Hospitalier National Universitaire de Fann, Universite Cheikh Anta Diop de Dakar, Dakar, Senegal

589 Enhanced Neutralization of HIV-1 With Fusion Inhibitor Resistant Mutations

Muntasir Alam[1]; Takeo Kuwata[1]; Kristel P. Ramirez[1]; Yasuhiro Maruta[1]; Kazuki Tanaka[1]; Kazuya Shimura[2]; Shinya Oishi[2]; Nobutaka Fujii[2]; Masao Matsuoka[2]; Shuzo Matsushita[1]

[1]Kumamoto University, Kumamoto, Japan; [2]Kyoto University, Kyoto, Japan

590 Mutations at the Bottom of the Phe43 Cavity Are Responsible for Cross-Resistance to NBD Analogues

Shigeyoshi Harada[1]; Yu Irahara[2]; Samatchaya Boonchawalit[1]; Mai Goryo[1]; Hirokazu Tamamura[2]; Tetsuro Matano[1]; Shuzo Matsushita[3]; Kazuhisa Yoshimura[1]

[1]National Institute of Infectious Diseases, Shinjuku, Japan; [2]Tokyo Medical and Dental University, Chiyoda, Japan; [3]Kumamoto University, Kumamoto, Japan

591 SIV_{mac239} Integrase as a Model of HIV Drug Resistance Against Integrase Inhibitors

Said Hassounah[1]; Thibault Mesplede[1]; Maureen Oliveira[1]; Peter K. Quashie[1]; Daniela Moisi[1]; Paul A. Sandstrom[2]; Mark A. Wainberg[1]; Bluma Brenner[1]

[1]McGill University, Montréal, Canada; [2]National HIV and Retrovirology Laboratory, National Microbiology Laboratory, Public Health Agency of Canada, Ottawa, Canada

592 Within-Run Cross-Contamination in Deep Sequencing Applications on the Illumina MiSeq

Chanson J. Brumme; Winnie Dong; Celia K. Chui; Richard Liang; Art F. Poon; Richard Harrigan

BC Centre for Excellence in HIV/AIDS, Vancouver, Canada

593 Analysis of Resistance Haplotypes Using Primer IDs and Next Gen Sequencing of HIV RNA

Valerie F. Boltz[1]; Jason Rausch[1]; Wei Shao[2]; Charles Coomer[1]; John W. Mellors[3]; Mary Kearney[1]; John M. Coffin[4]

[1]National Institutes of Health (NIH), Frederick, MD, US; [2]Leidos, Frederick, MD, US; [3]University of Pittsburgh, Pittsburgh, PA, US; [4]Tufts University, Boston, MA, US

Session P-L2 Poster Session — Poster Hall

2:30 pm – 4:00 pm

HIV Subtypes and Resistance

594 HIV-1 Subtype Influences the Pathways of Genotypic Resistance to Integrase Inhibitors

Tomas J. Doyle[1]; David Dunn[4]; Rolf Kaiser[3]; Erasmus Smit[10]; Anne-Genevieve Marcelin[5]; Carmen de Mendoza[6]; Javier Martínez-Picado[9]; Federico Garcia[7]; Francesca Ceccherini-Silberstein[8]; Anna Maria Geretti[2]
CORONET study group

[1]King's College London, London, United Kingdom; [2]University of Liverpool, Liverpool, United Kingdom; [3]University of Cologne, Cologne, Germany; [4]University College London, London, United Kingdom; [5]Hôpital Pitié Salpetriere, APHM, Paris, France; [6]Hospital Carlos III, Madrid, Spain; [7]University Hospital San Cecilio, Granada, Spain; [8]University of Rome Tor Vergata, Rome, Italy; [9]Institut de Recerca de la Sida, Barcelona, Spain; [10]Birmingham Heartlands Hospital, Birmingham, United Kingdom

595 Differences in Resistance Mutations in Non-B Subtypes at First-Line Failure in Africa

Cissy M. Kityo[1]; Sarah Walker[2]; Immaculate Nankya[1]; Anne Hoppe[2]; Jennifer Thompson[2]; Silvia Bertagnolio[3]; Philippa Easterbrook[3]; Peter Mugyenyi[1]; Nicholas Paton[4]
On behalf of the EARNEST Trial Team

[1]Joint Clinical Research Centre, Kampala, Uganda; [2]MRC Clinical Trials Unit at University College London, London, United Kingdom; [3]World Health Organization, Geneva, Switzerland; [4]Yong Loo Lin School of Medicine, Singapore, Singapore

596 K65R Detected More Frequently in HIV-1 Subtype C Viruses at Virological Failure

Erasmus Smit[1]; **Ellen White**[7]; Duncan Clark[4]; Duncan Churchill[2]; Hongyi Zhang[6]; Simon Collins[5]; Deenan Pillay[3]; Anna Tostevin[7]; David Dunn[7]
UKHDRD and UKCHIC

[1]Public Health England, Birmingham, United Kingdom; [2]Brighton and Sussex Hospitals NHS Trust, Brighton, United Kingdom; [3]University of KwaZulu-Nata and University College London, London, United Kingdom; [4]St Batholomew's and the London NHS Trust, London, United Kingdom; [5]HIV i-Base, London, United Kingdom; [6]Addenbrooke's Hospital, Cambridge, United Kingdom; [7]University College London, London, United Kingdom

597 Viral Failure and High K65R in Kenyan Patients on Tenofovir-Based First-Line Therapy

Katherine C. Brooks[2]; Lameck Diero[1]; Allison Delong[2]; Maya Balamane[2]; Marissa Reitsma[2]; Emmanuel Kemboi[3]; Millicent Orido[3]; Mia Coetzer[2]; Joseph Hogan[2]; Rami Kantor[2]

[1]Moi University, Eldoret, Kenya; [2]Brown University, Providence, RI, US; [3]Academic Model Providing Access to Healthcare, Eldoret, Kenya

Session P-L3 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Transmitted HIV Drug Resistance: Assessing the Threat

598 Large NNRTI-Resistant Transmission Cluster in Injection Drug Users From Saskatchewan

Alexander Wong[1]; Jaspreet Kambo[1]; Richard Harrigan[2]; Art F. Poon[2]; Jeffrey B. Joy[2]

[1]University of Saskatchewan, Regina, Canada; [2]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada

599 Transmitted Drug Resistance and Time of HIV Infection, New York State, 2006-2013

Zhengyan Wang[1]; Emily Walits[2]; Daniel E. Gordon[1]; Bridget J. Anderson[1]; Deepa Rajulu[1]; Ling Wang[1]; Lou C. Smith[1]

[1]New York State Department of Health, Albany, NY, US; [2]University at Albany, School of Public Health, Albany, NY, US

600 Transmitted HIV Drug Resistance Among Early Infected Persons in San Diego, California

Theppharit Panichsillapakit[1]; David M. Smith[2]; Joel Wertheim[2]; Douglas D. Richman[2]; Susan Little[2]; Sanjay Mehta[2]

[1]Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; [2]University of California San Diego (UCSD), La Jolla, CA, US

601 HIV Molecular Epidemiology and Transmitted Drug Resistance in the Mesoamerican Region

Claudia Garcia-Morales[1]; Santiago Avila-Rios[1]; Daniela Tapia-Trejo[1]; Carlos Mejía-Villatoro[2]; Juan M Pascale[3]; Guillermo Porras-Cortes[5]; Ivette Lorenzana[4]; Elsa Palou[4]; Marvin Manzanero[6]; Gustavo Reyes-Terán[1]

[1]National Institute of Respiratory DIsease, Mexico City, Mexico; [2]Roosevelt Hospital, Guatemala City, Guatemala; [3]Gorgas Memorial Institute for Health Studies, Panama City, Panama; [4]Universidad Nacional Autónoma de Honduras, Tegucigalpa, Honduras; [5]Vivian Pellas Metropolitan Hospital, Managua, Nicaragua; [6]Ministry of Health, Belize City, Belize

602 Temporal Trends of Transmitted HIV Drug Resistance Following Seroconversion

Ashley Olson[1]; Claudia Kucherer[3]; Anders Sönnerborg[4]; Carmen de Mendoza[5]; Robert Zangerle[6]; Maria Prins[9]; John Gill[2]; Anne-Marte Bakken Kran[7]; Dimitrios Paraskevis[8]; Kholoud Porter[1]
for CASCADE collaboration in EuroCoord

[1]University College London, London, United Kingdom; [2]University of Calgary, Alberta Health Services, Calgary, Canada; [3]Robert Koch Institute, Berlin, Germany; [4]Karolinska Institutet, Stockholm, Sweden; [5]Puerta de Hierro Research Institute and University Hospital, Madrid, Spain; [6]Innsbruck Medical University, Innsbruck, Austria; [7]Oslo University Hospital, Oslo, Norway; [8]University of Athens, Athens, Greece; [9]Public Health Service of Amsterdam, Amsterdam, Netherlands

603 Increase in HIV Primary Drug Resistance in a Demographic Surveillance Area in Rural KwaZulu-Natal South Africa

Justen Manasa; Siva Danaviah; Frank Tanser; Sureshnee Pillay; Hloniphile Mthiyane; Eduan Wilkinson; Deenan Pillay; **Tulio de Oliveira**

University of KwaZulu-Natal, Durban, South Africa

Session P-L4 Poster Session — Poster Hall

2:30 pm – 4:00 pm

HIV Drug Resistance: Global Perspective and Clinical Implications

604 A Clinical Prediction Rule for PI Resistance in Resource-Limited Settings

Karen Cohen[1]; Annemie Stewart[1]; Andre P. Kengne[1]; Rory F. Leisegang[1]; Marla Coetsee[2]; Shavani Maharaj[2]; Liezl Dunn[2]; Graeme Meintjes; Gert U. van Zyl[3]; Gary Maartens[1]

[1]University of Cape Town, Cape Town, South Africa; [2]Aid for AIDS Management (Pty) Ltd, Cape Town, South Africa; [3]University of Stellenbosch, Cape Town, South Africa

605 Baseline Low-Frequency HIV-1 Variants Do Not Predict Virologic Failure to RPV/FTC/TDF

Danielle P. Porter[1]; Martin Däumer[2]; Alexander Thielen[2]; Michael D. Miller[1]; Kirsten L. White[1]

[1]Gilead Sciences, Inc., Foster City, CA, US; [2]Seq-IT GmbH & Co KG, Kaiserslautern, Germany

606 High Rates of Early Virologic Failure in a Cohort of Tanzanian HIV-Infected Adults

Claudia A. Hawkins[1]; Nzovu Ulenga[2]; Enju Liu[3]; Said Aboud[4]; Ferdinand Mugusi[4]; Guerino Chalamilla[2]; David Sando[2]; Eric Aris[2]; Wafaie Fawzi[3]

[1]Northwestern University, Feinberg School of Medicine, Chicago, IL, US; [2]Management and Development for Health, Dar es Salaam, United Republic of Tanzania; [3]Harvard School of Public Health, Boston, MA, US; [4]Muhimbili University of Health and Allied Sciences, Dar es Salaam, United Republic of Tanzania

607 HIV Drug Resistance Surveillance in Honduras After 10 Years of Widespread ART

Claudia Garcia-Morales[1]; **Santiago Avila-Rios**[1]; Daniela Tapia-Trejo[1]; Rita Meza[2]; Sandra Nuñez-Rubio[2]; Norma Flores[5]; Wendy Murillo[3]; Ivette Lorenzana[3]; Elsa Palou[4]; Gustavo Reyes-Terán[1]

[1]National Institute of Respiratory Diseases, Mexico City, Mexico; [2]Honduran HIV National Program and National Laboratory, Tegucigalpa, Honduras; [3]Universidad Nacional Autónoma de Honduras, Tegucigalpa, Honduras; [4]Hospital Escuela Universitario, Tegucigalpa, Honduras; [5]Instituto Nacional Cardiopulmonar, Tegucigalpa, Honduras

608 High Prevalence of Genotypic Resistance to Integrase inhibitors of HIV-1 Strains in Taiwan

Sui-Yuan Chang[1]; Chien-Ching Hung[2]

[1]National Taiwan University, Taipei, Taiwan; [2]National Taiwan University Hospital and National Taiwan University College of Medicine, Taipei, Taiwan

609 Integrase Resistance Correlates of Response to Dolutegravir (DTG) Through 48 Weeks

Cindy L. Vavro; Jenny Huang; Mounir Ait-Khaled

GlaxoSmithKline, Research Triangle Park, NC, US

610 Discordant Predictions Could Impact Dolutegravir Use Upon Raltegravir Failure

Kristof Theys[1]; Ana B. Abecasis[2]; Pieter Libin[1]; Perpétua Gomes[2]; Joaquim Cabanas[3]; Ricardo J. Camacho[1]; Kristel Van Laethem[1]
the Portuguese HIV-1 Resistance Study Group

[1]University of Leuven, Leuven, Belgium; [2]Universidade Nova de Lisboa, Lisbon, Portugal; [3]Hospital Egas Moniz, Lisbon, Portugal

611 Integrase S119P Mutation Correlates With Disease Progression in HIV-1 Naïve Patients

Daniele Armenia[1]; Maria Mercedes Santoro[1]; Caterina Gori[2]; Emanuele Nicastri[2]; Antonio Cristaudo[3]; Massimo Andreoni[4]; Andrea Antinori[2]; Zeger Debyser[5]; Carlo-Federico Perno[2]; Francesca Ceccherini-Silberstein[1]

[1]University of Rome Tor Vergata, Rome, Italy; [2]L. Spallanzani Hospital, Rome, Italy; [3]San Gallicano Dermatological Institute, Rome, Italy; [4]University Hospital Tor Vergata, Rome, Italy; [5]Katholieke Universiteit Leuven, Leuven, Belgium

TUESDAY, FEBRUARY 24, 2015

Session P-M1 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Nucleic-Acid–Based Detection of HIV

612 A Generalized Entropy Measure of Viral Diversity for Identifying Recent HIV-1 Infections

Julia W. Wu; Oscar Patterson-Lomba; Marcello Pagano

Harvard School of Public Health, Boston, MA, US

613 Acute Infections, Cost and Time to Reporting of HIV Test Results in US State Public Health Laboratories

Muazzam Nasrullah[1]; Laura G. Wesolowski[1]; Steven F. Ethridge[1]; Kevin Cranston[2]; Robert A. Myers[3]; James T. Rudrik[4]; Angela B. Hutchinson[1]; Barbara G. Werner[2]

[1]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US; [2]Massachusetts Department of Public Health, Boston, MA, US; [3]Maryland Department of Health and Mental Hygiene, Baltimore, MD, US; [4]Michigan Department of Community Health, Lansing, MI, US

614 The POC Alere q HIV-1/2 Detect Test for Detection and Quantification of HIV-2

Ming Chang[1]; Katja Weimar[2]; Dana N. Raugi[1]; Robert A. Smith[1]; Selly Ba[3]; Moussa Seydi[3]; Katrin Steinmetzer[2]; Robert W. Coombs[1]; **Geoffrey S. Gottlieb**[1]
UW-Dakar HIV-2 Study Group

[1]University of Washington, Seattle, WA, US; [2]Alere Technologies GmbH, Jena, Germany; [3]Service des Maladies Infectieuses, CHNU de Fann, Dakar, Senegal

615 Performance of HIV Viral Load with Dried Blood Spots in Children on ART in Mozambique

Amina M. de Sousa Muhate[1]; James C. Houston[2]; Mariamo Assane[1]; Joy Chang[2]; Emilia Koumans[2]; Ilesh V. Jani[1]; Jennifer Sabatier[2]; Paula M. Vaz[3]; Chunfu Yang[2]; Emilia Rivadeneira[2]

[1]Ministry of Health, Mozambique, Mozambique; [2]Centers for Disease Control and Prevention, Atlanta, GA, US; [3]Fundação Ariel Glaser Contra o SIDA Pediátrico, Maputo, Mozambique

616 Cost-Effectiveness of Pooled PCR Testing of Dried Blood Spots for Infant HIV Diagnosis

Cari van Schalkwyk[2]; Jean Maritz[2]; **Alex Welte**[1]; Gert U. van Zyl[2]; Wolfgang Preiser[2]

[1]University of Stellenbosch, South Africa, Stellenbosch, South Africa; [2]University of Stellenbosch, Tygerberg, South Africa

617 Evaluating Dried Blood Spot Performance in Assessing HIV Treatment Failure in Uganda

Allen Roberts; Herbert C. Duber; Ming Chang; Anne Gasasira; Gloria Ikilezi; Jane Achan; Joan Dragavon; Glenda Daza; Emmanuela Gakidou; Robert W. Coombs

Makerere University College of Health Sciences, Kampala, Uganda

618 Comparison of Pooled RNA and 4th Gen Ag/Ab Testing to Identify Acute HIV Infection

Gary Murphy; Simon Carne; Bharati Patel; Elaine Mckinney; Samual Moses; Noel Gill; John Parry; Jennifer Tosswill

Public Health England, London, United Kingdom

619 Improved Viral Load Monitoring Capacity With Rank-Based Algorithms for Pooled Assays

Tao Liu[1]; **Joseph Hogan**[1]; Renxia Huang[3]; Rami Kantor[2]

[1]Brown University, Providence, RI, US; [2]Miriam Hospital, Alpert Medical School, Brown University, Providence, RI, US; [3]Fulcrum Analytics Inc, Fairfield, CT, US

WEDNESDAY, FEBRUARY 25, 2015

Session P-M2 Poster Session **Poster Hall**
2:30 pm – 4:00 pm

Comparison of HIV Incidence Assays

620 Evaluation of Determine™ HIV-1/2 Ag/Ab Combo in the Context of Acute HIV Screening

Silvina Masciotra[1]; S. Michele Owen[1]; Wei Luo[1]; Emily Westheimer[2]; Stephanie Cohen[3]; Laura Hall[4]; Cindy L. Gay[5]; Philip J. Peters[1]

[1]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US; [2]New York City Department of Health and Mental Hygiene, New York, NY, US; [3]San Francisco Department of Public Health, San Francisco, CA, US; [4]ICF International, Atlanta, GA, US; [5]University of North Carolina, Chapel Hill, NC, US

621 Performance of the Geenius HIV-1/HIV-2 Assay in the CDC HIV Testing Algorithm

Kevin P. Delaney; Steven Ethridge; Laura G. Wesolowski; MIchele Owen; Bernard M. Branson

US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US

622 The Effect of HIV-1 Subtype A, C and D on Cross-Sectional Incidence Assay Performance

Andrew F. Longosz[2]; Mary Grabowski[2]; Charles S. Morrison[3]; Ronald H. Gray[2]; Connie Celum[4]; Quarraisha Abdool Karim[5]; Hilmarie Brand[6]; Thomas C. Quinn[1]; Susan H. Eshleman[2]; **Oliver B. Laeyendecker**[1]

[1]National Institute of Allergy and Infectious Diseases, Baltimore, MD, US; [2]Johns Hopkins University, Baltimore, MD, US; [3]FHI 360, Durham, NC, US; [4]University of Washington, Seattle, WA, US; [5]CAPRISA, University of KwaZulu-Natal, Congella, South Africa; [6]SACEMA, Stellenbosch University, Stellenbosch, South Africa

623 Avidity Assay for Cross-Sectional Incidence Based on a 4th-Generation Combo Ag/Ab EIA

Allison R. Kirkpatrick[1]; Eshan U. Patel[1]; Connie L. Celum[2]; Richard D. Moore[3]; Joel N. Blankson[3]; Shruti H. Mehta[4]; Gregory D. Kirk[4]; Thomas C. Quinn[1]; Susan H. Eshleman[2]; Oliver B. Laeyendecker[1]

[1]National Institutes of Health, Baltimore, MD, US; [2]University of Washington, Seattle, WA, US; [3]Johns Hopkins University School of Medicine, Baltimore, MD, US; [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [5]Johns Hopkins University School of Medicine, Baltimore, MD, US

624 Estimation of HIV Incidence in a High-HIV-Prevalence Setting, South Nyanza, Kenya, 2012

Andrea A. Kim[1]; David Maman[2]; Harrison Fredrick Omondi[3]; Alex Morwabe[3]; Irene Mukui[4]; Valarie Opollo[3]; Beatrice Kirubi[5]; Jean-François Etard[2]; Martinus W. Borgdorff[7]; **Clement Zeh**[7]

[1]US Centers for Disease Control and Prevention, Dpo, AE, US; [2]Médecins Sans Frontières, Paris, France; [3]Kenya Medical Research Institute (KEMRI)/CDC Research and Public Health Collaboration, Kisumu, Kenya; [4]Kenya Ministry of Health, Nairobi, Kenya; [5]Médecins Sans Frontières, Nairobi, Kenya; [6]US Centers for Disease Control and Prevention (CDC), Kisumu, Kenya; [7]US Centers for Disease Control and Prevention (CDC), Kisumu, Kenya

625 False Recent Rates for Two Recent Infection Testing Algorithms, South Nyanza, Kenya

Clement Zeh[1]; David Maman[4]; Harrison Omondi[2]; Alex Morwabe[2]; Collins Odhiambo[2]; Beatrice Kirubi[4]; Irene Mukui[3]; Martinus W. Borgdorff[1]; Jean-François Etard[4]; Andrea A. Kim[1]

[1]US Centers for Disease Control and Prevention, Kisumu, Kenya; [2]Kenya Medical Research Institute, Kisumu, Kenya; [3]National AIDS and STI Control and Prevention, Nairobi, Kenya; [4]Médecins Sans Frontières, Paris, France

626 Viral Load is Critical in Limiting False-Recent Results From HIV Incidence Assays

Reshma Kassanjee[1]; Shelley Facente[2]; Sheila Keating[3]; Elaine McKinney[4]; Kara Marson[2]; Christopher D. Pilcher[2]; Michael Busch[3]; Gary Murphy[4]; **Alex Welte**[1]
The Consortium for the Evaluation and Performance of HIV Incidence Assays (CEPHIA)

[1]South African DST/NRF Centre of Excellence in Epidemiological Modelling and Analysis (SACEMA), University of Stellenbosch, Stellenbosch, South Africa; [2]University of California San Francisco, San Francisco, CA, US; [3]Blood Systems Research Institute, San Francisco, CA, US; [4]Public Health England, London, United Kingdom

627 Use of the Sample-to-Cutoff Ratio (S/CO) to Identify Recency of HIV-1 Infection

Eric M. Ramos; José Ortega; Glenda Daza; Yuree Namkung; Socorro Harb; Joan Dragavon; Robert W. Coombs

University of Washington, Seattle, WA, US

628 An Abbott Architect Combo Signal to Cut-Off Ratio With Adequate PPV to Confirm HIV

Tomas O. Jensen[1]; Peter Robertson[2]; **Jeffrey J. Post**[1]

[1]Prince of Wales Hospital, Randwick, Australia; [2]South Eastern Area Laboratory Services, Prince of Wales Hospital, Sydney, Australia

629 Determining HIV Status of African Adults With Discordant HIV Rapid Tests

Jessica M. Fogel[1]; Estelle Piwowar-Manning[1]; Mark A. Marzinke[1]; William Clarke[1]; Michal Kulich[2]; Jessie K. Mbwambo[3]; Linda Richter[4]; Glenda Gray[5]; Thomas J. Coates[6]; Susan H. Eshleman[1]

[1]Johns Hopkins University School of Medicine, Baltimore, MD, US; [2]Charles University, Prague, Czech Republic; [3]Muhimbili University Teaching Hospital, Dar es Salaam, United Republic of Tanzania; [4]Universities of the Witwatersrand and KwaZulu-Natal, Durban, South Africa; [5]South African Medical Research Council, Cape Town, South Africa; [6]David Geffen School of Medicine and University of California Los Angeles Health, Los Angeles, CA, US

Session P-M3 Poster Session — Poster Hall

2:30 pm – 4:00 pm

HIV Detection, Tropism, and CD4 Measurement

630 Accuracy of POC CD4 testing using microtube capillary sampling in Botswana households

Sikhulile Moyo[1]; Lillian Okui[1]; Hermann Bussmann[1]; Simani Gaseitsiwe[1]; Erik van Widenfeldt[1]; Molly P. Holme[2]; Joseph Makhema[1]; Shahin Lockman[2]; Vladimir Novitsky[2]; Max Essex[2]

[1]Botswana Harvard AIDS Institute Partnership, Gaborone, Botswana; [2]Harvard School of Public Health, Boston, MA, US

631 Zyomyx MyT4 and BD FACSPresto Comparison to the Pima CD4 Assay

Katie Tucker; Sehin Birhanu; Larry Westerman

US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US

632LB Point-of-Care CD4 (Pima) Impact on Linkage to Care With Home-Based HIV Testing, Kenya

Mitesh A. Desai[1]; Duncan Okal[2]; Robert T. Chen[1]; Richard Ndivo[2]; Charles Lebaron[1]; Tiffany Williams[1]; Fred Otieno[2]; Charles Rose[1]; Taraz Samandari[1]; Clement Zeh[1]

[1]US Centers for Disease Control and Prevention, Atlanta, GA, US; [2]Kenya Medical Research Institute, Kisumu, Kenya

633 Reliable Genotypic Tropism Tests for the Major HIV-1 Subtypes

Kieran Cashin[1]; Lachlan R. Gray[1]; Katherine L. Harvey[1]; Danielle Perez-Bercoff[2]; Guinevere Q. Lee[3]; Jasminka Sterjovski[1]; James F. Demarest[4]; Fraser Drummond[4]; Melissa J. Churchill[1]; Paul R. Gorry[1]

[1]Burnet Institute, Melbourne, Australia; [2]Centre Recherche Public de la Santé, Strassen, Luxembourg; [3]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada; [4]ViiV Healthcare, Durham, NC, US

634 Accuracy of Re-Reading HIV Rapid Tests and the Effect of Prolonged High Temperature

Augustine T. Choko[1]; Deus Thindwa[1]; Peter MacPherson[2]; Rodrick Sambakunsi[1]; Aaron Mdolo[1]; Kondwani Chiumya[1]; Owen Malema[3]; Simon Makombe[4]; Emily L. Webb[6]; **Elizabeth L. Corbett**[6]

[1]Malawi Liverpool Wellcome Trust Clinical Research Programme, Blantyre, Malawi; [2]University of Liverpool, Liverpool, United Kingdom; [3]Ministry of Health, Blantyre, Malawi; [4]Ministry of Health, Lilongwe, Malawi; [5]London School of Hygiene and Tropical Medicine, London, United Kingdom; [6]London School of Hygiene and Tropical Medicine, London, United Kingdom

635 Analysis of False Negative HIV Tests Based on Oral Fluid in 3 Clinical Trials

Marcel E. Curlin[1]; Michael T. Martin[1]; Wanna Leelawiwat[2]; Roman Gvetadze[1]; Charles Rose[1]; Sarika Pattanasin[2]; Richard Niska[1]; Timothy Holtz[1]; Kachit Choopanya[3]; Janet McNicholl[1]

[1]US Centers for Disease Control and Prevention, Apo, US; [2]Thailand Ministry of Public Health–Centers for Disease Control and Prevention Collaboration, Nonthaburi, Thailand; [3]Bangkok Tenofovir Study Group, Bangkok, Thailand

TUESDAY, FEBRUARY 24, 2015

Session P-N1 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Natural History and Prognosis of HCV Infection

636 Progression of Liver Disease in LHIV/HCV Coinfected People According to Gender in Icona Cohort: Role of Age as Potential Different Exposure to Estrogens

Antonella Cingolani[1]; Paola Cicconi[2]; Gloria Taliani[3]; Alessandro D. Cozzi-Lepri[4]; Massimo Puoti[5]; Carmela Pinnetti[6]; Pier Luigi Viale[7]; Antonella d'Arminio Monforte[2]
for Icona Foundation Study Group

[1]Catholic University, Roma, Italy; [2]University of Milano, Milano, Italy; [3]University La Sapienza, Roma, Italy; [4]University College London Medical School, Royal Free Campus, London, United Kingdom, London, United Kingdom; [5]Niguarda Hospital, Milano, Italy; [6]National Institute for Infectious Diseases L. Spallanzani, Roma, Italy; [7]Univeristy of Bologna, Bologna, Italy

637 A Prognostic Score Estimating the Risk of Liver-Related Death Among HIV/HCV Coinfected Subjects

Daniel Grint[1]; Lars Peters[2]; Jürgen Rockstroh[3]; Karine Lacombe[4]; Andrzej Horban[5]; Irina Khromova[8]; Jose Gatell[6]; Antonella d'Arminio Monforte[7]; Jens D. Lundgren[2]; **Amanda Mocroft**[1]
on behalf of EuroSIDA in EuroCoord

[1]University College London, London, United Kingdom; [2]University of Copenhagen, Copenhagen, Denmark; [3]University Hospital Bonn, Bonn, Germany; [4]Hospital Saint Antoine, Paris, France; [5]Wojewodzki Szpital Zakazny, Warsaw, Poland; [6]University of Barcelona, Barcelona, Spain; [7]Clinica delle Malattie Infettive e Tropicali, Milan, Italy; [8]Centre for HIV/AIDS & Infectious Diseases Prevention & Control, Kaliningrad, Russian Federation

638 Has Modern ART Reduced Endstage Liver Disease Risk in HIV-Hepatitis Coinfection?

Marina B. Klein[1]; Keri N. Althoff[3]; Yuezhou Jing[3]; Greg D. Kirk[3]; Vincent Lo Re[2]; Nina Kim[4]; Mari Kitahata[4]; Chloe Thio[3]; Michael J. Silverberg[5]; Richard Moore[3]
North American AIDS Cohort Collaboration on Research and Design (NA-ACCORD)

[1]McGill University Health Centre, Montreal, Canada; [2]University of Pennsylvania, Philadelphia, PA, US; [3]Johns Hopkins University, Baltimore, MD, US; [4]University of Washington, Washington, DC, US; [5]Kaiser Permanente Northern California, Oakland, CA, US

639 Marijuana Use Does Not Accelerate Liver Fibrosis in HCV/HIV-Coinfected Women

Erin M. Kelly[1]; Jennifer L. Dodge[1]; Monika Sarkar[1]; Audrey French[2]; Phyllis Tien[1]; Marshall Glesby[3]; Elizabeth Golub[4]; Michael Augenbraun[5]; Michael Plankey[6]; **Marion G. Peters**[1]
WIHS

[1]University of California San Francisco, San Francisco, CA, US; [2]CORE Center/Stroger Hospital, Chicago, IL, US; [3]Weill Cornell Medical College, New York City, NY, US; [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [5]State University of New York, Downstate Medical Center, Brooklyn, NY, US; [6]Georgetown University, Washington, DC, US

640 HIV Infection Does Not Worsen Prognosis of Liver Transplantation for Hepatocellular Carcinoma

Fernando H. Agüero[1]; Alejandro Forner[2]; Christian Manzardo[1]; Andres Valdivieso[3]; Marino Blanes[4]; Rafael Barcena[5]; Antoni Rafecas[1]; Lluis Castells[6]; Antonio Rimola[1]; Jose M Miro[1]

[1]University of Barcelona, Barcelona, Barcelona, Spain; [2]Hospital Clinic, IDIBAPS and El Centro de Investigación Biomédica en Red en el Área Temática de Enfermedades Hepáticas y Digestivas (CIBERehd), Barcelona, Spain; [3]Hospital Universitario de Cruces, Bilbao, Spain, Bilbao, Spain; [4]Hospital Universitario La Fe, Valencia, Spain, Valencia, Spain; [5]Hospital Universitario Ramón y Cajal, Madrid, Spain, Madrid, Spain; [6]Hospital Universitari Vall d'Hebrón, Barcelona, Spain, Barcelona, Spain

641 Rapid Progression to Cirrhosis and Death Among HCV-Infected Persons Who Inject Drugs in India

Shruti H. Mehta[1]; Suniti Solomon[2]; Allison M. McFall[1]; Aylur K. Srikrishnan[2]; Pachamuthu Balakrishnan[2]; Nandagopal P[2]; David L. Thomas[1]; Mark Sulkowski[1]; Sunil S. Solomon[1]

[1]Johns Hopkins University, Baltimore, MD, US; [2]YR Gaitonde Centre for AIDS Research and Education, Chennai, India

642 Chronic Kidney Disease Progression After HCV Seroconversion

Adeel A. Butt

University of Pittsburgh/VA Pittsburgh Healthcare System, Pittsburgh, PA, US

Session P-N2 Poster Session — Poster Hall

2:30 pm – 4:00 pm

HCV Therapy: Observations From Cohort Studies

643 Statins Improve SVR, Reduce Fibrosis Progression and HCC Among HCV+ Persons

Adeel A. Butt[1]; Peng Yan[2]; Obaid Shaikh[2]; Shari Rogal[2]

[1]University of Pittsburgh/VA Pittsburgh Healthcare System, Pittsburgh, PA, US; [2]VA Pittsburgh Healthcare System, Pittsburgh, PA, US

644 Sofosubuvir, Simeprevir, +/- Ribavirin in HCV Protease Inhibitor-Experienced Patients

Kristen M. Marks; Ethan M. Weinberg; Sonal Kumar; Carrie Down; Ype P. de Jong; Leah A. Burke; Mary C. Olson; Ira M. Jacobson

Weill Cornell Medical College, New York, NY, US

645 Effectiveness of Sofosbuvir/Simeprevir for HIV/HCV Patients in Clinical Practice

Jody Gilmore[1]; Kenneth Lynn[1]; Delisha Breen[1]; Stacey Trooskin[2]; Jihad Slim[3]; Nancy Scangarello[3]; Alvin Kingcade[4]; Katie Hunyh[4]; Vincent Lo Re[1]; **Jay R. Kostman**[1]

[1]Perelman School of Medicine, Philadelphia, PA, US; [2]Drexel University College of Medicine, Philadelphia, PA, US; [3]St Michael's Medical Center, Newark, NJ, US; [4]Philadelphia Health Management Corporation, Philadelphia, PA, US

646 German Cohort on Sofosbuvir-Based Therapy for HIV/HCV and HCV Infection (GECOSO)

Stefan Christensen[2]; Ingiliz Patrick[3]; Dietrich Hueppe[7]; Thomas Lutz[4]; Karl Georg Simon[6]; Knud Schewe[5]; Heiner Busch[2]; Axel Baumgarten[3]; Guenther Schmutz[1]; **Stefan Mauss**[1]

[1]Center for HIV and Hepatogastroenterology, Duesseldorf, Germany; [2]CIM Infectious Diseases, Muenster, Germany; [3]Medizinisches Infektiologie Zentrum Berlin, Berlin, Germany; [4]Infektiologikum, Frankfurt, Germany; [5]Infektionsmedizinisches Centrum Hamburg, Hamburg, Germany; [6]Practice for Gastroenterology Leverkusen, Leverkusen, Germany; [7]Practice for Gastroenterology Herne, Herne, Germany

647 Real-World Data on HIV-Positive Patients With HCV Treated With Sofosbuvir and/or Simeprevir

David Del Bello[1]; Kian Bichoupan[1]; Calley Levine[1]; Agnes Cha[2]; David Perlman[1]; Nadim H. Salomon[1]; Donald Kotler[1]; Daniel Fierer[1]; Douglas Dieterich[1]; Andrea Branch[1]

[1]Mount Sinai Health System, New York City, NY, US; [2]Brooklyn Medical Center, New York City, NY, US

648 Simeprevir and Sofosbuvir Regimens for Hepatitis C: Decompensation and Serious AEs

Ponni V. Perumalswami[1]; Kian Bichoupan[1]; Lawrence Ku[1]; Neal M. Patel[1]; Rachana Yalamanchili[1]; Thomas Schiano[1]; Mark Woodward[2]; Douglas Dieterich[1]; Andrea D. Branch[1]

[1]Icahn School of Medicine at Mount Sinai, New York, NY, US; [2]George Institute for Health at the University of Oxford, Oxford, United Kingdom

649 Successful HCV Treatment With Direct Acting Antivirals in HIV/HCV Patients

Jennifer L. Grant[1]; Valentina Stosor[1]; Frank J. Palella[1]; Richard M. Green[1]; Guajira Thomas[1]; Donna V. McGregor[1]; Milena M. McLaughlin[2]; Sudhir Penugonda[1]; Michael Angarone[1]; **Claudia Hawkins**[1]

[1]Northwestern University, Feinberg School of Medicine, Chicago, IL, US; [2]Midwestern University, Chicago, IL, US

650 Sofosbuvir/Daclatasvir in HIV/HCV Co-infected Patients With Extensive Liver Fibrosis

Alissa Naqvi; Francine Guillouet de Salvador; Isabelle Perbost; Brigitte Dunais; Aline Joulié; Rodolphe Garraffo; Pascal Pugliese; Jacques Durant; Pierre Marie Roger; Eric Rosenthal

Centre Hospitalier Universitaire de Nice, Nice, France

651 Majority of HIV/HCV Patients Need to Switch ART to Accommodate Simeprevir

Rebecca Cope[1]; Aaron Pickering[2]; Thomas Glowa[1]; Samantha Faulds[1]; Peter Veldkamp[1]; **Ramakrishna Prasad**[1]

[1]University of Pittsburgh, Pittsburgh, PA, US; [2]University of Maryland, Glen Burnie, MD, US

Session P-N3 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Treatment of HCV with DAAs: Short-Term Costs and Long-Term Benefits

652 Simeprevir/Sofosbuvir vs Triple Therapy (Telaprevir or Boceprevir) for HCV GT1: A cost analysis

Jacob A. Langness[1]; David Tabano[2]; Sarah Tise[3]; Lindsay Pratt[3]; Lauren Ayres[3]; Amanda Wieland[3]; Sonia Lin[1]; Vahram Ghuschcyan[2]; Kavita Nair[2]; Greg Everson[3]

[1]University of Colorado, Arvada, CO, US; [2]Skaggs School of Pharmacy and Pharmaceutical Sciences, University of Colorado, Aurora, CO, US; [3]University of Colorado, Aurora, CO, US

653 SVR Durability: HCV Patients Treated With IFN-Free DAA Regimens

Aurielle M. Thomas[1]; Sarah Kattakuzhy[1]; Sarah Jones[2]; Anita Kohli[1]; Wilson Eleanor[2]; Angie Price[2]; Rachel Silk[2]; Zayani Sims[1]; Anu Osinusi[3]; Shyam Kottilil[3]

[1]The National Institutes of Health, Bethesda, MD, US; [2]Leidos Biomedical Research, Inc., Bethesda, MD, US; [3]Institute of Human Virology, University of Maryland, Baltimore, MD, US

654 Five–Year Risk of Late Relapse or Reinfection With Hepatitis C After Sustained Virological Response: Meta-analysis of 49 Studies in 8534 Patients

Andrew M. Hill[1]; Bryony Simmons[2]; Jawaad Saleem[2]; Graham Cooke[2]

[1]Chelsea and Westminster Hospital, London, United Kingdom; [2]St Mary's Hospital–Imperial College Healthcare NHS Trust, London, United Kingdom

655 Incidence of Extrahepatic Complications in HIV/HCV Patients Who Achieved SVR

Sebastiano Leone[1]; Mattia Prosperi[2]; Silvia Costarelli[1]; Francesco Castelli[3]; Franco Maggiolo[4]; Simona Di Giambenedetto[5]; Annalisa Saracino[6]; Massimo Di Pietro[7]; Fabio Zacchi[8]; Andrea Gori[1]

656 Impact of SVR on Liver Decompensation and Hepatic Fibrosis Markers in HIV/HCV

Janet Tate[1]; E. John Wherry[2]; Jay R. Kostman[2]; Debika Bhattacharya[4]; Guadalupe Garcia-Tsao[5]; Cynthia Gibert[6]; Joseph K. Lim[5]; David Rimland[3]; Amy Justice[1]; **Vincent Lo Re**[2]
Veterans Aging Cohort Study Project Team

[1]VA Connecticute Health System, West Haven, CT, US; [2]Univeristy of Pennsylvania, Philadelphia, PA, US; [3]Atlanta VA Healthcare System, Atlanta, GA, US; [4]VA Greater Los Angeles, Los Angeles, CA, US; [5]Yale University School of Medicine, New Haven, CT, US; [6]Washington DC VA Medical Center, Washington, DC, US

657 Portal Pressure Changes After HCV Eradication in HIV/HCV+ Patients With Cirrhosis

Matilde Sánchez-Conde; Leire Pérez-Latorre; Diego Rincón; Pilar Miralles; María Vega Catalina; Juan Carlos López; Rafael Bañares; **Juan Berenguer**

Hospital General Universitario Gregorio Marañón, Madrid, Spain

Session P-N4 Poster Session — Poster Hall

2:30 pm – 4:00 pm

HCV: Getting the Drugs to Those Who Need Them

658 Assessment of PCP Knowledge of HCV Screening, Recommendations, and Treatment Options

Allison Brodsky; Monique Allen; Gregory Johnson; Lora Magaldi; Carolyn Moy; Nancy Tursi; Stephanie Tzarnas; Stacey Trooskin

Drexel University College of Medicine, Philadelphia, PA, US

659 Majority of HCV/HIV-Infected Patients in the Netherlands Remain in Need of Effective HCV Treatment

Colette Smit[1]; Joop E. Arends[2]; Marc van der Valk[3]; Kees Brinkman[4]; Heidi Ammerlaan[5]; S. Arend[6]; Peter Reiss[1]; Clemens Richter[7]

[1]Stichting HIV Monitoring, Amsterdam, Netherlands; [2]Universitair Medisch Centrum Utrecht, Utrecht, Netherlands; [3]Academic Medical Center, Amsterdam, Netherlands; [4]Onze Lieve Vrouwe Gasthuis, Amsterdam, Netherlands; [5]CZE, Eindhoven, Netherlands; [6]Leiden University Medical Center, Leiden, Netherlands; [7]Rijnstate Ziekenhuis, Arnhem, Netherlands

660 Identifying and Prioritizing Hepatitis C Treatment for HIV-Hepatitis C Co-Infection

Amanda D. Castel[1]; Mariah M. Kalmin[1]; Rachel Hart[2]; Alan Greenberg[1]; Henry Masur[3]
DC Cohort Executive Committee

[1]The Milken Institute School of Public Health at George Washington University, Washington, DC, US; [2]Cerner Corporation, Kansas City, MO, US; [3]National Institutes of Health (NIH), Bethesda, MD, US

661 One-Year Results of a Community-Based Hepatitis C Testing and Linkage-to-Care Program

Christian B. Ramers[1]; Robert Lewis[1]; Letty Reyes[1]; Danelle Wallace[1]; Robert Gish[3]; David Wyles[2]; Alex Kuo[1]

[1]Family Health Centers of San Diego, San Diego, CA, US; [2]University of California San Diego, La Jolla, CA, US; [3]Stanford University, Palo Alto, CA, US

WEDNESDAY, FEBRUARY 25, 2015

Session P-N5 Poster Session — Poster Hall

2:30 pm – 4:00 pm

HCV: Epidemiology and Case Detection

662 Hepatitis C and B Testing Among HIV-Infected Individuals in England

Sam Lattimore; Sarah Collins; Celia Penman; Lukasz Cieply; Sema Mandal
Sentinel Surveillance of Blood-Borne Virus Testing
Public Health England, London, United Kingdom

663 WITHDRAWN

664 HCV 2k/1b Recombinant Form among Hepatitis C–Infected Genotype 2 Patients in Georgia

Marika Karchava[1]; Jesper Waldenstrom[2]; Monica M. Parker[3]; Renee Hallack[3]; Lali Sharvadze[1]; Lana Gatserelia[1]; Nikoloz Chkhartishvili[1]; Natia Dvali[1]; Helen Norder[2]; Tengiz Tsertsvadze[1]

[1]Infectious Diseases, AIDS and Clinical Immunology Research Center, Tbilisi, Georgia; [2]Institute of Biomedicine, University of Gothenburg, Gothenburg, Sweden; [3]Wadsworth Center, Albany, NY, US

665 High HCV Prevalence Among Baby Boomers in Surveillance-Identified High HIV Risk Areas

Irene Kuo[1]; Meriam Mikre[1]; A. Toni Young[2]; Geoffrey Maugham[2]; Amanda D. Castel[1]

[1]George Washington University, Washington, DC, US; [2]Community Education Group, Washington, DC, US

666 Low HCV Screening Uptake of the Current Birth Cohort Testing Guidelines

Alexander G. Geboy[1]; Hyun A. Cha[1]; Idene E. Perez[1]; Matthew T. Bell[1]; Sandeep Mahajan[2]; Adebisi O. Ayodele[2]; Dawn A. Fishbein[2]

[1]MedStar Health Research Institute, Hyattsville, MD, US; [2]MedStar Washington Hospital Center, Washington, DC, US

667 Evaluation of CDC Recommendations for HCV Testing in an Urban Emergency Department

Yu-Hsiang Hsieh[3]; Richard Rothman[3]; Oliver B. Laeyendecker[2]; Gabor Kelen[3]; Ama Avornu[3]; Eshan U. Patel[2]; Jim Kim[3]; Risha Irvin[3]; David L. Thomas[3]; Thomas C. Quinn[2]

[1]Johns Hopkins University School of Medicine, Baltimore, MD, US; [2]National Institute of Allergy and Infectious Diseases, Baltimore, MD, US; [3]Johns Hopkins University School of Medicine, Baltimore, MD, US

668 Impact of Integrating EMR HCV Testing Prompts in a Difficult to Navigate EMR System

Stephanie Tzarnas[2]; Monique Allen[2]; Allison Brodsky[2]; Gregory Johnson[2]; Lora Magaldi[2]; Carolyn Moy[2]; Nancy Tursi[2]; Steven Zivich[2]; Stacey Trooskin[2]

[1]Drexel University College of Medicine, Philadelphia, PA, US; [2]Drexel University College of Medicine, Philadelphia, PA, US; [3]Drexel University College of Medicine, Philadelphia, PA, US; [4]Drexel University College of Medicine, Philadelphia, PA, US

Session P-N6 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Acute HCV Infection

669 SVR12 Results After 12w Boceprevir + P/R in the Dutch Acute Hepatitis C in HIV Study

Sebastiaan J. Hullegie[8]; Mark A. Claassen[8]; Guido E. van den Berk[2]; Jan T. van der Meer[1]; Joop E. Arends[3]; Clemens Richter[4]; Dirk Posthouwer[5]; Peter P. Koopmans[6]; Fanny N. Lauw[7]; Bart J. Rijnders[8]

[1]Academic Medical Center University of Amsterdam, Amsterdam, Netherlands; [2]Onze Lieve Vrouwe Gasthuis, Amsterdam, Netherlands; [3]University Medical Center Utrecht, Utrecht, Netherlands; [4]Rijnstate Ziekenhuis, Arnhem, Netherlands; [5]Maastricht University Medical Center, Maastricht, Netherlands; [6]Radboud University Medical Center, Nijmegen, Netherlands; [7]Slotervaart Ziekenhuis, Amsterdam, Netherlands; [8]Erasmus University Medical Center, Rotterdam, Netherlands

670 Does the Availability of New DAAs Influence Treatment Uptake in Acute Hepatitis C in HIV Coinfection?

Christoph Boesecke[1]; Mark Nelson[2]; Patrick Ingiliz[5]; Thomas Lutz[3]; Stefan H. Scholten[4]; Christoph D. Spinner[6]; Michael Rausch[9]; Thomas Reiberger[7]; Stefan Mauss[8]; Jürgen Rockstroh[1]

[1]Bonn University Hospital, Bonn, Germany; [2]Chelsea and Westminster Hospital, NHS Foundation Trust, London, United Kingdom; [3]Infektiologikum, Frankfurt/Main, Germany; [4]Praxis Hohenstaufenring, Cologne, Germany; [5]MiB, Berlin, Germany; [6]Interdisciplinary HIV Centre (IZAR), University Hospital Klinikum Rechts der Isar, Munich, Germany; [7]Medical University of Vienna, Vienna, Austria; [8]Center for HIV and Hepatogastroenterology, Duesseldorf, Germany; [9]Aerztezentrum Nollendorfplatz, Berlin, Germany

671 Long-Term Follow-Up of HIV-Positive Men Who Have Sex With Men (MSM) With Acute Hepatitis C Virus (HCV) Infection: High Rates of Treatment and Low Rates of Liver-Related Complications

Patrick Ingiliz[1]; Anders C. Boyd[3]; Katharina Steininger[1]; Andreas Carganico[1]; Stephan Dupke[1]; Ivanka Krznaric[1]; Marcel Schuetze[1]; Stefan Neifer[2]; Martin J. Obermeier[1]; Axel Baumgarten[1]

[1]Medical Center for Infectious Diseases, Berlin, Germany; [2]Microbiology Laboratory, Berlin, Germany; [3]INSERM UMR_S 1136, Paris, France

672 Hepatitis C in Men Who Have Sex with Men With New HIV Diagnoses in Los Angeles

Kara W. Chew[1]; Marjan Javanbakht[2]; Laurel Clare[1]; Lorelei Bornfleth[1]; Debika Bhattacharya[1]; Pamina Gorbach[2]; Martha L. Blum[3]

[1]David Geffen School of Medicine at UCLA, Los Angeles, CA, US; [2]UCLA Fielding School of Public Health, Los Angeles, CA, US; [3]Community Hospital of the Monterey Peninsula, Monterey, CA, US

673 Development and Comparison of Hepatitis C Cross-Sectional Incidence Testing Methods

Eshan U. Patel[1]; Andrea Cox[2]; Shruti H. Mehta[3]; Caroline E. Mullis[2]; Jeffrey Quinn[2]; Gregory D. Kirk[3]; Thomas C. Quinn[1]; Oliver B. Laeyendecker[1]

[1]National Institute of Allergy and Infectious Diseases (NIAID), Baltimore, MD, US; [2]Johns Hopkins University School of Medicine, Baltimore, MD, US; [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US

674 Risk Factors for Transmission of HCV Among HIV-Infected MSM: A Case-Control Study

Joost W. Vanhommerig[1]; Femke A. Lambers[1]; Janke Schinkel[2]; Joop E. Arends[3]; Fanny N. Lauw[4]; Kees Brinkman[5]; Luuk Gras[6]; Bart J. Rijnders[7]; Jan T. van der Meer[2]; Maria Prins[1]

675 Behavioural and Treatment Interventions to Reduce HCV Transmissions in HIV+ MSM

Luisa Salazar-Vizcaya[1]; Roger Kouyos[2]; Cindy Zahnd[1]; Manuel Battegay[3]; Katharine Darling[4]; Alexandra Calmy[5]; Pietro L. Vernazza[6]; Olivia Keiser[1]; Andri Rauch[7]
On behalf of the Swiss HIV Cohort Study

[1]University of Bern, Bern, Switzerland; [2]University Hospital Zurich, Zürich, Switzerland; [3]University Hospital Basel, Basel, Switzerland; [4]Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland; [5]Geneva University Hospitals, Geneva, Switzerland; [6]Kantonsspital St Gallen, St Gallen, Switzerland; [7]University Hospital Bern, Inselspital, Bern, Switzerland

Session P-N7 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Immunopathogenesis of HCV Infection

676 Macrophage Activation and Hepatitis C (HCV) Disease Progression in HIV-Infected Women Participating in the Women's Interagency HIV Study (WIHS)

Audrey L. French[1]; Charlesnika Evans[3]; Marion G. Peters[2]; Mary A. Young[4]; Mark Kuniholm[6]; Michael Augenbraun[7]; Seema N. Desai[5]

[1]CORE Center/ Stroger Hospital of Cook County, Chicago, IL, US; [2]University of California San Francisco, San Francisco, CA, US; [3]Northwestern University, Chicago, IL, US; [4]Georgetown University, Washington, IL, US; [5]Rush University Medical Center, Chicago, IL, US; [6]Montefiore Medical Center, University Hospital for Albert Einstein College of Medicine, Bronx, NY, US; [7]State University of New York Downstate, Brooklyn, NY, US

677 HIV/HCV Co-Infection Accelerated Liver Disease is Associated With Induction of M2-Like Macrophages

Moses T. Bility[1]; Feng Li[1]; Junichi Nunoya[1]; Guangming Li[1]; Eoin Feeney[2]; Raymond Chung[2]; Lishan Su[1]

[1]University of North Carolina, Chapel Hill, NC, US; [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US

678 HIV Infection Is Associated With an Impaired Anti-HCV Activity of NK-Like T Cells

Pavlos Kokordelis[1]; Benjamin Krämer[1]; Christoph Boesecke[1]; Esther Voigt[2]; Patrick Ingiliz[3]; Andreas Glässner[1]; Franziska Wolter[1]; Ulrich Spengler[1]; Jürgen K. Rockstroh[1]; Jacob Nattermann[1]

[1]University of Bonn, Bonn, Germany; [2]Praxis am Ebertplatz, Cologne, Germany; [3]Medical Center for Infectious Diseases, Berlin, Germany

679 Dys-Regulated Cross Talk Between CD4+ T Cells and NK Cells in HIV/HCV Coinfection

Benjamin Krämer[1]; Andreas Glässner[1]; Claudia Zwank[1]; Felix Goeser[1]; Christoph Boesecke[1]; Patrick Ingiliz[2]; Christian P. Strassburg[1]; Ulrich Spengler[1]; Jürgen Rockstroh[1]; Jacob Nattermann[1]

[1]University of Bonn, Bonn, Germany; [2]Medical Center for Infectious Diseases, Berlin, Germany

680 HIV/HCV Coinfection Is Associated With Significant Alterations of the NK Cell Pool

Dominik J. Kaczmarek[1]; Pavlos Kokordelis[1]; Benjamin Krämer[1]; Andreas Glässner[1]; Franziska Wolter[1]; Patrick Ingiliz[2]; Christian P. Strassburg[1]; Ulrich Spengler[1]; Jürgen Rockstroh[1]; Jacob Nattermann[1]

[1]University of Bonn, Bonn, Germany; [2]Medical Center for Infectious Diseases, Berlin, Germany

681 Dynamic Changes of CXCL10 Isoforms and DPP4 During IFN-Free Treatment for HCV

Eric G. Meissner[1]; Jeremie Decalf[2]; Armanda Casrouge[2]; Henry Masur[3]; Shyam Kottilil[4]; Darragh Duffy[2]; Matthew L. Albert[2]

[1]Medical University of South Carolina, Charleston, SC, US; [2]Institut Pasteur, Paris, France; [3]National Institutes of Health (NIH), Bethesda, MD, US; [4]University of Maryland School of Medicine, Baltimore, MD, US

682 Mx1 and OAS1-2 SNPs Are Related With Severity of Liver Disease in HIV/HCV Coinfection

Mónica García-Álvarez[1]; Juan Berenguer[2]; Daniel Pineda-Tenor[1]; Maria Ángeles Jiménez-Sousa[1]; María Guzmán-Fulgencio[1]; Ana Carrero[2]; Teresa Aldamiz-Echevarria[2]; Francisco Tejerina[2]; Cristina Diez[2]; Salvador Resino[1]

[1]Centro Nacional de Microbiología, Instituto de Salud Carlos III, Madrid, Spain; [2]Hospital General Universitario Gregorio Marañón, Madrid, Spain

683 Treatment With DCV Plus ASV Reduces Immune Activation in HIV/HCV Coinfected Patients

Eleanor M. Wilson[4]; Anita Kohli[3]; Julia B. Purdy[3]; Louisa Howard[1]; Sabrina Mangat[1]; Gebeyehu Teferi[2]; John Hogan[2]; Henry Masur[3]; Shyam Kottilil[1]

[1]National Institutes of Health (NIH), Bethesda, MD, US; [2]Unity Health Care, Washington, DC, US; [3]NIH, Bethesda, MD, US; [4]Leidos Biomedical Services, Inc, Bethesda, MD, US

684 Innate Immune Activation Pathways Overlap, Yet Are Distinct in HCV and HIV Infection

Lenche Kostadinova; Benigno Rodriguez; Donald Anthony

Case Western Reserve University, Cleveland, OH, US

685 A Novel Mechanism of Resistance to Multiple bNAbs Revealed by Natural Variation in Panel of 199 HCVpp

Ramy El-Diwany; Lisa Wasilewski; Madeleine Mankowski; Stuart C. Ray; Justin R. Bailey

Johns Hopkins University School of Medicine, Baltimore, MD, US

686 Single-Variant Sequencing Revealed Rapid HCV Evolution in HIV Immune Reconstitution

Lin Liu; David Nardo; Eric Li; Gary Wang

University of Florida, Gainesville, FL, US

THURSDAY, FEBRUARY 26, 2015

Session P-N8 Poster Session **Poster Hall**

2:30 pm – 4:00 pm

HCV Therapeutics: Preclinical Observations and Clinical Trials of DAAs

687 UNITY-1: Daclatasvir/Asunaprevir/Beclabuvir for HCV Genotype 1 Without Cirrhosis

Fred Poordad[1], William Sievert[2], Norbert Brau[3], **Samuel Lee**[4], Jean-Pierre Bronowicki[5], Ira Jacobson[6], Eric Hughes[7], Eugene Swenson[8], Philip Yin[8]
On behalf of the UNITY-1 Study Team

[1]Texas Liver Institute, San Antonio, Texas, United States; [2]Monash Health and Monash University, Melbourne, Victoria, Australia; [3]Bronx Veterans Affairs Medical Center, New York, New York, United States; [4]University of Calgary, Alberta Health Services, Calgary, Alberta, Canada; [5]Centre Hospitalier Universitaire de Nancy, Universite de Lorraine, Vandoeuvre les Nancy, France; [6]Weill Cornell Medical College, New York, New York, United States; [7]Bristol-Myers Squibb Co, Princeton, New Jersey, United States; [8]Bristol-Myers Squibb Co, Wallingford, Connecticut, United States

688 UNITY-2: Daclatasvir/Asunaprevir/Beclabuvir ± RBV for HCV Genotype 1 With Cirrhosis

Andrew Muir[1], Fred Poordad[2], Jay Lalezari[3], Gregory Dore[4], Christophe Hezode[5], Alnoor Ramji[6], Eric Hughes[7], **Eugene Swenson**[8], Philip Yin[88]
On behalf of the UNITY-2 Study Team

[1]Duke Clinical Research Institute, Duke University School of Medicine, Durham, North Carolina, United States; [2]Texas Liver Institute, University of Texas Health Science, San Antonio, Texas, United States; [3]Quest Clinical Research, San Francisco, California, United States; [4]Kirby Institute, University of New South Wales Australia, Sydney, New South Wales, Australia; [5]Hópital Henri Mondor, Université Paris-Est, Créteil, France; [6]University of British Columbia, Vancouver, British Columbia, Canada; [7]Bristol-Myers Squibb Co, Princeton, New Jersey, United States; [8]Bristol-Myers Squibb Co, Wallingford, Connecticut, United States

689 Utility of Hepatitis C Viral-Load Monitoring With Ledipasvir and Sofosbuvir Therapy

Sreetha Sidharthan[2]; Anita Kohli[3]; Anu Osinusi[2]; Amy Nelson[1]; Zayani Sims[2]; Kerry S. Townsend[4]; Lydia Tang[1]; Michael Polis[4]; Henry Masur[2]; Shyam Kottilil[1]

[1]Institute of Human Virology, University of Maryland, Baltimore, MD, US; [2]NIH Clinical Center, Bethesda, MD, US; [3]Leidos Biomedical Research, Inc., Frederick, MD, US; [4]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD, US

690 Viral Kinetic Profiles of HCV Response to Telaprevir-Based Therapy in Patients With Hemophilia

Kenneth E. Sherman[1]; Ruian Ke[2]; Susan D. Rouster[1]; Alan S. Perelson[2]

[1]University of Cincinnati, Cincinnati, OH, US; [2]Los Alamos National Laboratory, Los Alamos, NM, US

691 Hematologic Analysis of ABT-450/r/Ombitasvir and Dasabuvir + RBV in TURQUOISE-I

Robert S. Brown[1]; David Wyles[2]; Jihad Slim[3]; Peter J. Ruane[4]; Barbara McGovern[5]; Roger Trinh[5]; Yiran Hu[5]; Joseph J. Eron[6]

[1]Johns Hopkins University, Baltimore, MD, US; [2]University of California San Diego, La Jolla, CA, US; [3]St Michael's Medical Center, Newark, NJ, US; [4]Peter J. Ruane MD Inc, Los Angeles, CA, US; [5]AbbVie, Inc, North Chicago, IL, US; [6]University of North Carolina, Chapel Hill, NC, US

692 Effect of HIV Coinfection on Adherence to a 12-Week Regimen of HCV Therapy With Ledipasvir/Sofosbuvir

Kerry S. Townsend[1]; Tess L. Petersen[2]; Lori A. Gordon[2]; Amy Nelson[1]; Cassie Seamon[2]; Chloe Gross[3]; Anu Osinusi[2]; Michael A. Polis[1]; Henry Masur[2]; Shyam Kottilil[1]

[1]National Institute of Allergy and Infectious Diseases, Bethesda, MD, US; [2]National Institutes of Health, Bethesda, MD, US; [3]Leidos Biomedical 18 Research Inc, Frederick, MD, US

693 Investigation of the Role of Macrocyclization in HCV Protease Inhibitor MK-5172

Djadé I. Soumana; Kristina Prachanronarong; Nese Kurt Yilmaz; Ali Akbar; Cihan Aydin; Celia A. Schiffer

University of Massachusetts Medical School, Worcester, MA, US

Session P-N9 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Mental Health and Treatment Adherence with Direct-Acting Antivirals

694 Impact of Baseline Mental Health on Adherence to Interferon-Free HCV Therapy

Jack Masur[1]; Lydia Tang[1]; Amy Nelson[1]; Anu Osinusi[1]; Anita Kohli[2]; Rachel Silk[2]; Chloe Gross[2]; Sarah Kattakuzhy[2]; Michael Polis[3]; Shyam Kottilil[1]

[1]University of Maryland, Baltimore, MD, US; [2]National Institutes of Health, Bethesda, MD, US; [3]National Institutes of Health, Bethesda, MD, US

695 Mental Health Impact of HCV Treatment in HIV/HCV Patients: DAA vs IFN-Based Therapy

Louise Lundgren[1]; Sarah Kattakuzhy[2]; Angie Price[2]; Catherine Seamon[3]; Amy Nelson[4]; Anita Kohli[2]; Rachel Silk[2]; Chloe Gross[2]; Henry Masur[1]; Shyamasundaran Kottilil[4]

[1]National Institutes of Health Clinical Center, Bethesda, MD, US; [2]Leidos Biomedical Research, Inc, Frederick, MD, US; [3]Laboratory of Immunoregulation, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, US; [4]Institute of Human Virology, University of Maryland, Baltimore, MD, US

Session P-N10 Poster Session — Poster Hall

2:30 pm – 4:00 pm

HCV: Resistance to Antiviral Agents

696 Characterization of Naturally Occurring Resistance to HCV NS5A Inhibitors

Jennifer Cook; Owen Solberg; Alicia Newton; Suqin Cai; Arne Frantzell; Jacqueline Reeves; Christos J Petropoulos; Jonathan Toma; **Wei Huang**

Monogram Biosciences, South San Francisco, CA, US

697 Hepatitis C Q80K Prevalence in BC, Canada, Determined by a Public Domain Assay

Jeffrey B. Joy[1]; Celia K. Chui[1]; Chanson J. Brumme[1]; Mel Krajden[2]; Andrea Olmstead[2]; Winnie Dong[1]; Wendy Zhang[1]; Aram Karakas[1]; Huong Hew[3]; Richard Harrigan[1]

[1]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada; [2]BC Centre for Disease Control, Vancouver, Canada; [3]Janssen Pharmaceuticals, Inc., Toronto, Canada

698 HCVNS3 Variants in HIV/HCV Coinfected Patients Before-After PegIFN/Ribavirin

Enass Abdel-Hameed[1]; Susan D. Rouster[1]; Xiang Zhang[2]; Jing Chen[2]; Mario Medvedovic[2]; Kenneth E. Sherman[1]

[1]University of Cincinnati, Cincinnati, OH, US; [2]University of Cincinnati, Cincinnati, OH, US

699 Compensatory Mutations in HCV NS5A/B Coevolve in Patients Failing NS3 Inhibitors

Velia Chiara Di Maio[1]; Valeria Cento[1]; Daniele Di Paolo[2]; Sergio Babudieri[3]; Gloria Taliani[4]; Giustino Parruti[5]; Giuliano Rizzardini[6]; Mario Angelico[2]; Carlo Federico Perno[1]; **Francesca Ceccherini-Silberstein**[1]

[1]University of Rome Tor Vergata, Rome, Italy; [2]University Hospital of Rome Tor Vergata, Rome, Italy; [3]University of Sassari, Sassari, Italy; [4]University of Rome La Sapienza, Rome, Italy; [5]Pescara General Hospital, Pescara, Italy; [6]Hospital Sacco of Milan, Milan, Italy

Session P-N11 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Other Hepatitis Viruses: HBV, HDV, HEV

700 Hepatitis B Vaccine Response in Children Attending Rwanda Military Hospital

Judy T. Orikiiriza[1]; Louis Mujuwisha[2]; Elizabeth Karlsson[3]; Vincent Mutabazi[4]; Johan Normark[3]

[1]Infectious Diseases Institute Makerere College of Health Sciences, Kampala, Uganda; [2]University of Rwanda, Kigali, Rwanda; [3]Umea Infectious Diseases Institute, Kigali, Sweden; [4]Rwanda Biomedical Center, Kigali, Rwanda

701 Revaccinating HIV+ Adults With Double vs Standard HBV Regimen: ANRS B-BOOST Trial

David Rey[1]; Cécilie Dufour[2]; Marie-Josée Wendling[3]; Patrick Miailhes[4]; Philippe Sogni[8]; Georges Haour[2]; Marie-Louise Michel[7]; Lionel Piroth[6]; Odile Launay[5]; Fabrice Carrat[2]

[1]University Hospital Strasbourg, Strasbourg, France; [2]Université Pierre et Marie Curie, Strasbourg, France; [3]Hôpitaux Universitaires Strasbourg, Strasbourg, France; [4]University Hospital of Lyon, Lyon, France; [5]CIC Vaccinologie, Paris, France; [6]University Hospital of Dijon, Dijon, France; [7]Institut Pasteur, Paris, France; [8]Cochin Hospital, Paris, France

702 Complex HBV Quasispecies Affects Immunogenicity in Acute Hepatitis B Infection

Valentina Svicher[1]; Marianna Aragri[1]; Nicola Coppola[2]; Claudia Alteri[1]; Arianna Battisti[1]; Caterina Sagnelli[2]; Mariantonietta Pisaturo[2]; MariaConcetta Bellocchi[1]; Evangelista Sagnelli[2]; Carlo-Federico Perno[1]

[1]University of Rome Tor Vergata, Rome, Italy; [2]Second University of Naples, Naples, Italy

703 Higher Rate of Hepatitis B Antigen and Anti-HBV Antibody Seroconversion Among HIV/Chronic Hepatitis B Coinfection Initiating HBV Active HAART From Thailand

Anchalee Avihingsanon[1]; Opass Putcharoen[2]; Salyavit Chittmittrapap[2]; Tanakorn Apornpong[1]; Vorapot Sapsirisavat[1]; Sasiwimol Ubolyam[1]; Stephen J. Kerr[1]; Kiat Ruxrungtham[1]

On behalf of the HIV-NAT 105 Study Team

[1]HIV Netherlands Australia Thailand Research Collaboration, Thai Red Cross - AIDS Research Centre, Patumwan, Thailand; [2]Chulalongkorn University, Bangkok, Thailand

704 Occult HBV/HIV Coinfection and Validation of Cost-Effective NAT Pooling PCR

Shanmugam Saravanan[1]; Janardhanan Mohanakrishnan[1]; Thongadi Ramesh Dinesha[1]; Jayaseelan Boobalan[1]; Pachamuthu Balakrishnan[1]; Kailapuri G Murugavel[1]; Sunil S Solomon[2]; Suniti Solomon[1]; Davey M. Smith[3]

[1]YRG Centre for AIDS Research and Education, Chennai, India; [2]Johns Hopkins University School of Medicine, Baltimore, MD, US; [3]University of California San Diego, San Diego, CA, US

705 Invariant Natural Killer T-Cells in HIV-HBV Coinfection

Matteo Basilissi[1]; Camilla Tincati[1]; Esther Merlini[1]; Elisabetta Sinigaglia[2]; Javier Sanchez-Martinez[2]; Giovanni Carpani[2]; Antonella d'Arminio Monforte[1]; Laura Milazzo[1]; Giulia Marchetti[1]

[1]University of Milan, Milan, Italy; [2]San Paolo Hospital, Milan, Italy

706 Effect of Immunosuppression and Antivirals on Intracellular HBV Replication in HIV-HBV Coinfection

Anders C. Boyd[1]; Karine Lacombe[1]; Fabien Lavocat[2]; Sarah Maylin[3]; Patrick Miailhes[4]; Caroline Lascoux-Combe[5]; Constance Delaugerre[3]; Pierre-Marie Girard[1]; Fabien Zoulim[2]

[1]Inserm UMR_S1136, Paris, France; [2]Inserm U1052, Lyon, France; [3]Inserm U941, Paris, France; [4]Hospices Civils de Lyon, Lyon, France; [5]Hôpital Saint-Louis AP-HP, Paris, France

707 Prevalence of HDV in a Midwestern HIV-HBV Coinfected Population

Sanam Razeghi; Susan Rouster; Kenneth E. Sherman

University of Cincinnati, Cincinnati, OH, US

708LB Oral Prenylation Inhibition With Lonafarnib in Chronic Hepatitis D Infection: A Randomized, Double-Blinded, Placebo-Controlled Proof-of-Concept Study

Christopher Koh[1]; Laetitia Canini[7]; Harel Dahari[2]; David Cory[3]; Ingrid Choong[3]; David Kleiner[4]; Stewart Cooper[6]; Mark A. Winters[5]; Jeffrey Glenn[5]; Theo Heller[1]

[1]National Institute of Diabetes and Digestive and Kidney Diseases, NIH, Fulton, MD, US; [2]Loyola University Medical Center, Maywood, IL, US; [3]Eiger BioPharmaceuticals, San Carlos, CA, US; [4]National Cancer Institute, Bethesda, MD, US; [5]Stanford University, Stanford, CA, US; [6]California Pacific Medical Center, Palo Alto, CA, US; [7]University of Edinburgh, Edinburgh, United Kingdom

709 Incidence of Hepatitis E Virus in HIV-Infected Patients: A Longitudinal Prospective Study

Antonio Rivero-Juarez[1]; Loreto Martinez-Dueñas[1]; Antonio Martinez-Peinado[2]; Angela Camacho[1]; Celia Cifuentes[3]; Ana Gordon[1]; Mario Frias[1]; Julian Torre-Cisneros[1]; Juan A. Pineda[3]; Antonio Rivero[1]

[1]Instituto Maimonides de Investigación Biomédica de Córdoba, Cordoba, Spain; [2]Instituto Maimonides de Investigación Biomedica de Córdoba, Cordoba, Spain; [3]Hospital Universitario de Valme, Seville, Spain

TUESDAY, FEBRUARY 24, 2015

Session P-01 Poster Session — Poster Hall

2:30 pm – 4:00 pm

HPV Infections and Cancers

710 Factors Associated With Extensive Cervical Lesions Among HIV-Infected Women Screening for AIDS Clinical Trials Group (ACTG) Protocol A5282

Timothy J. Wilkin[1]; Roy Matining[2]; Vikrant Sahasrabuddhe[3]; Catherine Godfrey[4]; Thandie Lungu[5]; Mulindi Mwanahamuntu[6]; Ramesh Bhosale[7]; Scott Evans[2]; Robert W. Coombs[8]; Cynthia Firnhaber[9]

[1]Weill Cornell Medical College, New York, NY, US; [2]Harvard School of Public Health, Center for Biostatistics in AIDS Research, Cambridge, MA, US; [3]National Cancer Institute (NCI), Bethesda, MD, US; [4]Division of AIDS (DAIDS), NIAID, NIH, Bethesda, MD, US; [5]University of North Carolina Project–Malawi, Lilongwe, Malawi; [6]University Teaching Hospital, Lusaka, Zambia; [7]Byramjee Jeejeebhoy Medical College, Pune, India; [8]University of Washington, Seattle, WA, US; [9]University of Witswatersand, Johannesburg, South Africa

711 HIV Infection and Survival Among Women With Cervical Cancer in Botswana

Scott Dryden-Peterson[1]; Memory Bvochora-Nsingo[2]; Heluf Medhin[3]; Gita Suneja[4]; Aida Asmelash[5]; Malebogo Pusoentsi[3]; Anthony Russell[6]; Jason Efstathiou[6]; Bruce Chabner[6]; Shahin Lockman[1]

[1]Brigham and Women's Hospital, Harvard Medical School, Jamaica Plain, MA, US; [2]Gaborone Private Hospital, Gaborone, Botswana; [3]Botswana Ministry of Health, Gaborone, Botswana; [4]University of Utah, Salt Lake City, UT, US; [5]Botswana Harvard AIDS Institute, Gaborone, Botswana; [6]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US

712 Potential Cost-Effectiveness of Cervical Cancer Screening of HIV-Positive Kenyan Women

Marita Mann; Joseph Babigumira; Louis Garrison; Michael Chung

University of Washington, Seattle, WA, US

713 Anal High-Risk Human Papillomavirus (HPV) Infection Among HIV-Infected MSM in the SUN Study, 2004-2011

Pragna Patel[1]; Tim Bush[1]; Erna Kojic[2]; Lois Conley[1]; Elizabeth Unger[1]; Teresa Darragh[3]; Keith Henry[4]; John Hammer[5]; Nur Onen[6]; Joel Palefsky[3]

[1]CDC, Atlanta, GA, US; [2]Brown University, Providence, RI, US; [3]University of California San Francisco, San Francisco, CA, US; [4]University of Minnesota, Minneapolis, MN, US; [5]Denver Infectious Diseases Consultants, Denver, CO, US; [6]Washington University School of Medicine, St. Louis, MO, US

714 Long-Term Effectiveness of Electrocautery Ablation of HGAIN in HIV-Infected MSM

Joaquin Burgos[1]; Adria Curran[1]; Natalia Tallada[1]; Ana Guelar[2]; Jordi Navarro[1]; Stefania Landolfi[1]; Judith Villar[2]; Manel Crespo[1]; Esteve Ribera[1]; Vicenç Falco[1]

[1]University Hospital Vall d'Hebron, Barcelona, Spain; [2]University Hospital del Mar, Barcelona, Spain

715 Survival and Treatment Trends for Squamous Cell Carcinoma of the Anus in HIV Infection

Robert A. Pitts; Stephen Goldstone; Keith Sigel; Michael M. Gaisa; Carlie Sigel; Juan Wisnivesky

Icahn School of Medicine at Mount Sinai, New York, NY, US

716 Oral HPV Shedding and Warts After Starting Antiretroviral Therapy: ACTG Protocol A5272

Caroline H. Shiboski[1]; Anthony Lee[2]; Jennifer Webster-Cyriaque[3]; Huichao Chen[2]; Malcolm John[1]; Raphael J. Landovitz[4]; Mark Jacobson[1]

Oral HIV/AIDS Research Alliance and the AIDS Clinical Trial Group

[1]University of California San Francisco, San Francisco, CA, US; [2]Harvard School of Public Health, Center for Biostatistics in AIDS Research, Boston, MA, US; [3]University of North Carolina, Chapel Hill, NC, US; [4]University of California Los Angeles, Los Angeles, CA, US

717 Excess Risk of Rectal Squamous Cell Carcinoma in HIV-Infected Persons

Anna E. Coghill; Meredith S. Shiels; Eric A. Engels

National Cancer Institute, Rockville, MD, US

WEDNESDAY, FEBRUARY 25, 2015

Session P-02 Poster Session — Poster Hall

2:30 pm – 4:00 pm

AIDS-Related Cancers: Lymphoma and KS

718 Incidence and Outcomes of HIV-Associated Lymphomas in Botswana

Michael G. Milligan[1]; Elizabeth Bigger[3]; Musimar Zola[7]; Mukendi Kayembe[6]; Heluf Medhin[5]; Gita Suneja[4]; Shahin Lockman[2]; Jeremy Abramson[3]; Bruce Chabner[3]; Scott Dryden-Peterson[2]

[1]Harvard Medical School, Brookline, MA, US; [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, US; [3]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [4]University of Utah, Salt Lake City, UT, US; [5]Botswana Ministry of Health, Gaborone, Botswana; [6]Botswana National Health Laboratory, Gaborone, Botswana; [7]Princess Marina Hospital, Gaborone, Botswana

719 CHOP Is Feasible for HIV-Associated Lymphoma in the ART Era in Malawi

Satish Gopal[2]; Yuri Fedoriw[1]; Agnes Moses[2]; Nathan Montgomery[1]; Wongani Kaimila[2]; Coxcilly Kampani[2]; Robert Krysiak[2]; Kristy Richards[1]; Thomas Shea[1]; George Liomba[2]

[1]University of North Carolina, Chapel Hill, NC, US; [2]University of North Carolina Project–Malawi, Lilongwe, Malawi

720 Chronic Hepatitis B and C Infection and Risk for Non-Hodgkin Lymphoma in HIV-Infected Patients

Heiner C. Bucher

On behalf of the Collaboration of Observational HIV Epidemiological Research Europe (COHERE) in EuroCoord

University Hospital Basel, Basel, Switzerland

721 HIV-Associated Kaposi Sarcoma Treated With Chemotherapy and ART in Rural Malawi

Michael E. Herce[1]; Noel Kalanga[2]; Jonathan T. Crocker[2]; Emily B. Wroe[2]; James W. Keck[2]; Felix D. Chingoli[3]; Satish Gopal[1]; Junior Bazile[2]; Jason A. Beste[2]; Jonas Rigodon[2]

[1]University of North Carolina, Chapel Hill, NC, US; [2]Partners In Health, Neno, Malawi; [3]Ministry of Health of the Republic of Malawi, Neno, Malawi

722 High Mobility Group Box 1 (HMGB1) and HIV-Associated Kaposi Sarcoma in Africa

Helen Byakwaga[1]; Peter W. Hunt[3]; Miriam O. Laker-Oketta[2]; Albert R. Davalos[6]; Conrad Muzoora[1]; David V. Glidden[3]; A. Rain Mocello[3]; David R. Bangsberg[4]; Edward Mbidde[5]; Jeffrey N. Martin[3]

[1]Mbarara University of Science and Technology, Mbarara, Uganda; [2]Infectious Diseases Institute, Kampala, Uganda; [3]University of California San Francisco, San Francisco, CA, US; [4]Massachusetts General Hospital, Center for Global Health, Harvard Medical School, Boston, MA, US; [5]Uganda Virus Research Institute, Entebbe, Uganda; [6]Buck Institute for Research on Aging, Novato, CA, US

723 The CXCL12/CXCR4-CXCR7 Pathway, a Trio Implicated in Kaposi Sarcoma Pathogenesis

Aude Desnoyer[2]; Francoise Gaudin[2]; Agnes Carlotti[3]; Nicolas Dupin[3]; Francois Boue[2]; Karl Balabanian[2]; **Valérie Martinez-Pourcher**[1]

[1]Hopital Pitié-Salpêtrière, Paris, France; [2]Inserm, Univ Paris-Sud, LABEX LERMIT, UMR_S996, Clamart, France; [3]Dermatology, Paris, France

THURSDAY, FEBRUARY 26, 2015

Session P-03 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Cancer and Cancer Risk in HIV Subpopulations and Lung Cancer

724 Cancer in HIV-Infected Children: Record Linkage Study in South Africa

Julia Bohlius[6]; Nicky Maxwell[2]; Brian Eley[3]; Hans Prozesky[4]; Shobna Sawry[1]; Karl-Günter Technau[1]; Alan Davidson[2]; Cristina Stefan[5]; **Matthias Egger**[6]

On behalf of IeDEA Southern Africa

[1]University of the Witwatersrand, Johannesburg, South Africa; [2]University of Cape Town, Cape Town, South Africa; [3]Red Cross War Memorial Children's Hospital, Cape Town, South Africa; [4]University of Stellenbosch and Tygerberg Academic Hospital, Cape Town, South Africa; [5]Stellenbosch University and Tygerberg Hospital, Cape Town, South Africa; [6]University of Bern, Bern, Switzerland

725 High Cancer Risk Among the HIV-Infected Elderly in the United States

Elizabeth L. Yanik; Hormuzd A. Katki; Eric A. Engels

National Cancer Institute (NCI), Rockville, MD, US

726 Smoking Outweighs HIV-Related Risk Factors for Non–AIDS-Defining Cancers

Keri N. Althoff[1]; Stephen J. Gange[1]; Chad Achenbach[2]; Lisa P. Jacobson[1]; Angel M. Mayor[3]; Michael J. Silverberg[4]; Amy Justice[5]; Richard Moore[6]; Yuezhou Jing[1]; Kelly Gebo[6]
On behalf of the North American AIDS Cohort Collaboration on Research and Design

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [2]Northwestern University, Feinberg School of Medicine, Chicago, IL, US; [3]Universidad Central del Caribe, Bayamon, US; [4]Kaiser Permanente Northern California, Oakland, CA, US; [5]Veterans Affairs Connecticut Healthcare System and Yale Schools of Medicine and Public Health, New Haven, CT, US; [6]Johns Hopkins University School of Medicine, Baltimore, MD, US

727 High Frequency of Early Lung Cancer Diagnosis With Chest CT in HIV-Infected Smokers

Alain Makinson[1]; Sabrina Eymard-Duvernay[2]; François Raffi[3]; Fabrice Bonnet[4]; Laurence Thirard[5]; Pierre Tattevin[6]; Sophie Abgrall[7]; Jacques Reynes[1]; Vincent Le Moing[1]
on behalf of the ANRS EP48 HIV CHEST Study Team

[1]University Hospital Montpellier, UMI233, Montpellier, France; [2]UMI 233, IRD, University Montpellier 1, Montpellier, France; [3]Nantes University Hospital, Nantes, France; [4]University Hospital Bordeaux, Inserm U897, Bordeaux, France; [5]Tourcoing University Hospital, Tourcoing, France; [6]Pontchaillou University Hospital, Rennes, France; [7]University Hospital Avicennes, Bobigny, France; [8]ANRS, Paris, France

728 CD4 Measures as Predictors of Lung Cancer Risk and Prognosis in HIV Infection

Keith Sigel[1]; Kristina Crothers[2]; Kirsha Gordon[3]; Sheldon Brown[4]; David Rimland[5]; Maria Rodriguez-Barradas[6]; Cynthia Gibert[7]; Matthew B. Goetz[8]; Roger Bedimo[9]; Robert Dubrow[10]

[1]Icahn School of Medicine at Mount Sinai, New York, NY, US; [2]University of Washington School of Medicine, Seattle, WA, US; [3]VA Connecticut Healthcare System and Yale University Schools of Medicine and Public Health, New Haven, CT, US; [4]James J. Peters VA Medical Center, Bronx, NY, US; [5]Atlanta VA Medical Center, Atlanta, GA, US; [6]Michael E. DeBakey Veterans Affairs Medical Center, Houston, TX, US; [7]Washington DC Veterans Affairs Medical Center, Washington, DC, US; [8]Los Angeles VA Medical Center, Los Angeles, CA, US; [9]Veterans Affairs North Texas Health Care System, Dallas, TX, US; [10]Yale University School of Public Health, New Haven, CT, US

TUESDAY, FEBRUARY 24, 2015

Session P-P1 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Cardiovascular Disease Outcomes

729 Cardiovascular Disease Mortality Among HIV-Infected Persons, New York City, 2001–2012

David B. Hanna[1]; Chitra Ramaswamy[2]; Robert C. Kaplan[1]; Regina Zimmerman[2]; Sarah L. Braunstein[2]

[1]Albert Einstein College of Medicine, Bronx, NY, US; [2]New York City Department of Health and Mental Hygiene, Long Island City, NY, US

730 Angiographic Restenosis After PTCA in HIV-Infected Patients: Incidence and Predictors

Dominik Promny[3]; **Christoph D. Spinner**[1]; Salvatore Cassese[2]; Isabell Bernlochner[3]; Christian Bradaric[3]; Karl-Ludwig Laugwitz[3]; Adnan Kastrati[2]; Simon Schneider[3]

[1]University Hospital Klinikum Rechts der Isar, Munich, Germany; [2]Deutsches Herzzentrum Muenchen, Munich, Germany; [3]University Hospital Klinikum Rechts der Isar, Munich, Germany

WEDNESDAY, FEBRUARY 25, 2015

Session P-P2 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Dyslipidemia: Mediators and Treatment

731 PCSK9 Is Elevated in HIV+ Patients and May Mediate HIV-Associated Dyslipidemia

Payal Kohli[1]; Peter Ganz[1]; Yifei Ma[1]; Rebecca Scherzer[1]; Kristinalisa Maka[1]; Scott Wasserman[2]; Rob Scott[2]; Priscilla Hsue[1]

[1]University of California San Francisco, San Francisco, CA, US; [2]Amgen, Thousand Oaks, CA, US

732 Enhanced, Not Inhibited Monocyte Cholesterol Efflux Characterises Untreated HIV

Jane A. O'Halloran[2]; Therese Herlihy[2]; Alan Macken[2]; Louise Rainford[2]; John S. Lambert[2]; Gerard J. Sheehan[2]; Niall G. Mahon[2]; Leo P. Lawler[2]; Patrick W. Mallon[2]

[1]University College Dublin, Dublin, Ireland; [2]University College Dublin, Dublin, Ireland; [3]University College Dublin, Dublin, Ireland; [4]University College Dublin, Dublin, Ireland; [5]University College Dublin, Dublin, Ireland

733 Rosuvastatin vs Protease Inhibitor Switch for Hypercholesterolemia: Randomised Trial

Frederick J. Lee[7]; Polyana Monteiro[3]; David Baker[1]; Mark Bloch[2]; Robert Finlayson[8]; Richard Moore[5]; Norman Roth[6]; Jennifer F. Hoy[4]; Esteban Martinez[3]; Andrew Carr[7]

[1]East Sydney Doctors, Sydney, Australia; [2]Holdsworth House Medical Practice, Sydney, Australia; [3]Hospital Clinic, University of Barcelona, Barcelona, Spain; [4]Monash University/Alfred Hospital, Melbourne, Australia; [5]Northside Clinic, Melbourne, Australia; [6]Prahran Market Clinic, Melbourne, Australia; [7]St. Vincent's Hospital, Sydney, Australia; [8]Taylor Square Private Clinic, Sydney, Australia

734 Application of New ACC/AHA Cholesterol Guidelines to an HIV Clinical Care Cohort

Mosepele Mosepele[4]; Susan Regan[1]; James B. Meigs[1]; Steven Grinspoon[1]; Virginia A. Triant[1]

[1]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [3]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [4]Harvard School of Public Health, Boston, MA, US

Session P-P3 Poster Session — Poster Hall

2:30 pm – 4:00 pm

ART: Cardiovascular Risk and Hypertension

735 ICAM-1 Overexpression Induced by Abacavir is Mediated by $P2X_7$ Receptors

Carmen de Pablo; Victor Collado-Diaz; Samuel Orden; Cesar Rios-Navarro; Juan Esplugues; **Angeles Alvarez**

University of Valencia, Valencia, Spain

736 Changes in Platelet Function Following Abacavir Administration: A Pilot Study

Janine M. Trevillyan[2]; Elizabeth E. Gardiner[2]; Jane F. Arthur[2]; Jing Jing[2]; Robert K. Andrews[2]; Jennifer F. Hoy[2]

[1]Monash University, Melbourne, Australia; [2]Monash University, Melbourne, Australia

737 An RCT of Rilpivirine vs Efavirenz on Cardiovascular Risk in Healthy Volunteers

Samir K. Gupta[1]; James E. Slaven[1]; Ziyue Liu[1]

[1]Indiana University School of Medicine, Indianapolis, IN, US; [2]Indiana University, School of Medicine, Indianapolis, IN, US

738 Elvitegravir Reduces Monocyte Activation and Vascular Inflammation More Than Efavirenz

Corrilynn O. Hileman[1]; Bruce Kinley[1]; Valeska Scharen-Guivel[2]; Kathy Melbourne[2]; Javier Szwarcberg[2]; Janet Robinson[1]; Michael M Lederman[1]; Grace A. McComsey[1]

[1]Case Western Reserve University, Cleveland, OH, US; [2]Gilead Sciences, Inc., Foster City, CA, US

739 Impact of Antiretroviral Drugs on Hypertension in HIV-Positive Persons: D:A:D Study

Camilla I. Hatleberg[1]; Lene Ryom[1]; Antonella d'Arminio Monforte[2]; Eric Fontas[3]; Peter Reiss[4]; Ole Kirk[1]; Wafaa M. El-Sadr[5]; Stéphane De Wit[6]; Jens D. Lundgren[1]; Caroline Sabin[7]
On behalf of the D:A:D Study group

[1]Rigshospitalet, University of Copenhagen, Copenhagen, Denmark; [2]San Paolo University Hospital, Milan, Italy; [3]Nice University Hospital, Nice, France; [4]Academic Medical Center, University of Amsterdam, Amstredam, Netherlands; [5]Columbia University, New York, NY, US; [6]Centre Hospitalier Universitaire St. Pierre Hospital, Brussels, Belgium; [7]University College London, London, United Kingdom

740 Population-Based Assessment of Hypertension Among HIV Patients in Rural Uganda

Dalsone Kwarisiima[1]; Prashant Kotwani[3]; Norton Sang[4]; Florence Mwangwa[2]; Vivek Jain[3]; Dathan Byonanebye[2]; James Ayieko[4]; Laura Balzer[5]; Diane Havlir[3]; Moses R. Kamya[6]

[1]Makerere University Joint AIDS Program, Kampala, Uganda; [2]Infectious Disease Research Collaboration, Kampala, Uganda; [3]University of California San Francisco, San Francisco, CA, US; [4]Research Care Training Program, Kenya Medical Research Institute, Nairobi, Kenya; [5]University of Berkeley, Berkeley, CA, US; [6]Makerere University College of Health Sciences, Kampala, Uganda

TUESDAY, FEBRUARY 24, 2015

Session P-P4 Poster Session — Poster Hall

2:30 pm – 4:00 pm

What Predicts Risk for CVD in HIV?

741 CD4/CD8 Ratio, Age, and Serious Noninfectious Outcomes in HIV-Infected Adults

Jessica L. Castilho; Megan Turner; Sally Bebawy; Bryan E. Shepherd; Timothy Sterling

Vanderbilt University School of Medicine, Nashville, TN, US

742 Relationship Between Confirmed eGFR and Cardiovascular Disease in HIV-Positive Persons

Lene Ryom[1]; Jens D. Lundgren[1]; Peter Reiss[2]; Michael Ross[3]; Christoph Fux[4]; Philippe Morlat[7]; Olivier Moranne[5]; Colette Smith[6]; Caroline Sabin[6]; Amanda Mocroft[6]
On Behalf of the D:A:D Study Group

[1]CHIP, Department of Infectious Diseases and Rheumatology, Rigshospitalet and University of Copenhagen, Copenhagen, Denmark; [2]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands; [3]Division of Nephrology, Mount Sinai School of Medicine, New York, New York City, NY, US; [4]Clinic for Infectious Diseases and Hospital Hygiene, Kantonsspital Aarau, Aarau, Switzerland; [5]Nephrology department, Public Health department, CHU Nice, Nice, France; [6]University College London, London, United Kingdom; [7]University of Bordeaux, INSERM U 897, CHU de Bordeaux, Bordeaux, France

743 Smoking, Other Substance Use and Coronary Atherosclerosis Among HIV-Infected and Uninfected Men

Sean G. Kelly[1]; Michael Plankey[3]; Wendy Post[2]; Xiuhong Li[2]; Ron Stall[4]; Lisa P. Jacobson[2]; Mallory Witt[5]; Lawrence Kingsley[4]; Christopher Cox[2]; Frank J. Palella[1]

[1]Northwestern University, Chicago, IL, US; [2]Johns Hopkins University School of Medicine, Baltimore, MD, US; [3]Georgetown University, Washington, DC, US; [4]University of Pittsburgh, Pittsburgh, PA, US; [5]University of California Los Angeles, Los Angeles, CA, US

744 Pericardial Fat Density: A Novel Marker of Cardiometabolic Risk in HIV Infection

Chris T. Longenecker; Mark Schlucter; Yiying Liu; Grace A. McComsey

Case Western Reserve University, Cleveland, OH, US

745 The Effect of Physical Activity on Cardiometabolic Health and Inflammation in HIV

Sahera Dirajlal-Fargo[1]; Allison R. Webel[2]; Bruce Kinley[3]; Danielle Labbato[3]; Ying Jiang[4]; Sara M. Debanne[4]; Grace A. McComsey[1]

[1]Rainbow Babies and Children's Hospital, Case Western Reserve University School of Medicine, Cleveland, OH, US; [2]Frances Payne Bolton School of Nursing Case Western Reserve University, Cleveland, OH, US; [3]University Hospitals Case Medical Center, Cleveland, OH, US; [4]Case Western Reserve University, Cleveland, OH, US

WEDNESDAY, FEBRUARY 25, 2015

Session P-P5 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Cardiovascular Risk Prediction

746 Cumulative HIV Care Measures Highly Associated With Acute Myocardial Infarction

Jorge L. Salinas[1]; Christopher T. Rentsch[2]; Vincent C. Marconi[1]; Janet Tate[3]; Adeel A. Butt[4]; Matthew S. Freiberg[4]; Matthew B. Goetz[5]; Maria Rodriguez-Barradas[6]; Amy Justice[3]; David Rimland[1]

[1]Emory University, Atlanta, GA, US; [2]Atlanta VA Hospital, Decatur, GA, US; [3]Yale University, New Haven, CT, US; [4]University of Pittsburgh, Pittsburgh, PA, US; [5]David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA, US; [6]Baylor College of Medicine, Houston, TX, US

747 Cardiovascular Disease Risk Prediction in the HIV Outpatient Study (HOPS)

Angela M. Thompson-Paul[1]; **Kenneth A. Lichtenstein**[2]; Carl Armon[3]; Kate Buchacz[1]; Rachel Debes[3]; Joan S. Chmiel[4]; Frank J. Palella[4]; Stanley C. Wei[1]; Jacek Skarbinski[1]; John T. Brooks[1]

[1]US Centers for Disease Control and Prevention, Atlanta, GA, US; [2]National Jewish Health, Denver, CO, US; [3]Cerner Corporation, Vienna, VA, US; [4]Northwestern University, Feinberg School of Medicine, Chicago, IL, US

748 Incidence and Risk of Myocardial Infarction (MI) by Type in the NA-ACCORD

Daniel R. Drozd[1]; Mari M. Kitahata[1]; Keri N. Althoff[2]; Jinbing Zhang[2]; Susan R. Heckbert[1]; Matthew J. Budoff[3]; Frank J. Palella[4]; Daniel B. Klein[5]; Richard D. Moore[6]; Heidi M. Crane[1]

[1]University of Washington, Seattle, WA, US; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [3]University of California Los Angeles, Los Angeles, CA, US; [4]Northwestern University, Chicago, IL, US; [5]Kaiser Permanente Northern California, Hayward, CA, US; [6]Johns Hopkins University, Baltimore, MD, US

749LB Abacavir Use and Risk for Myocardial Infarction in the NA-ACCORD

Frank J. Palella[1]; Keri N. Althoff[2]; Richard Moore[3]; Jinbing Zhang[2]; Mari Kitahata[4]; Stephen J. Gange[2]; Heidi M. Crane[4]; Daniel R. Drozd[4]; John T. Brooks[5]; Richard Elion[6]

[1]Northwestern University, Feinberg School of Medicine, Chicago, IL, US; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [3]Johns Hopkins University, Baltimore, MD, US; [4]University of Washington, Seattle, WA, US; [5]US Centers for Disease Control and Prevention, Atlanta, GA, US; [6]George Washington University, Washington, DC, US

750 HIV-Infected Veterans and the New ACC/AHA Cholesterol Guidelines: Got Statins?

Meredith E. Clement[1]; Lawrence Park[1]; Ann Marie Navar-Boggan[1]; Nwora L. Okeke[1]; Michael Pencina[1]; Pamela Douglas[1]; Susanna Naggie[1]

[1]Duke University, Durham, NC, US; [2]Duke University, Durham, NC, US; [3]Duke University, Durham, NC, US

751 Evaluation of the ACC/AHA CVD Risk Prediction Algorithm Among HIV-Infected Patients

Susan Regan[2]; James B. Meigs[2]; Joseph Massaro[3]; Ralph B. D'Agostino[3]; Steven Grinspoon[2]; **Virginia A. Triant**[2]

[1]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [3]Boston University, Boston, MA, US; [4]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US

TUESDAY, FEBRUARY 24, 2015

Session P-P6 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Biomarkers and Atherosclerosis

752 IL-6 and CD8 Senescence Independently Associate With Atherosclerosis in Treated HIV

Denise C. Hsu[1]; Zonghui Hu[1]; Courtney Carroll[2]; Kristinalisa Maka[2]; Adam Rupert[3]; Steven Deeks[2]; S. C. Kalapus[2]; Priscilla Hsue[2]; Irini Sereti[1]

[1]National Institute of Allergy and Infectious Diseases, Bethesda, MD, US; [2]University of California San Francisco, San Francisco, CA, US; [3]Leidos Biomedical Research, Inc, Frederick, MD, US

753 sCD163 Correlates With IMT and Macrophages in Aorta and Heart With HIV Infection

Joshua A. Walker[1]; Graham A. Beck[1]; Andrew D. Miller[2]; Tricia H. Burdo[1]; Kenneth C. Williams[1]

[1]Boston College, Chestnut Hill, MA, US; [2]Cornell University, Ithaca, NY, US

754 Non-Classical Monocytes Predict Progression of Carotid Intima-Media Thickness

Dominic C. Chow[1]; Jamie M. Kagihara[1]; Guangxiang G. Zhang[1]; Scott A. Souza[1]; Brooks I. Mitchell[1]; Beau K. Nakamoto[1]; Kalpana J. Kallianpur[1]; Robert J. Matyas[2]; Lishomwa C. Ndhlovu[1]; Cecilia M. Shikuma[1]

[1]University of Hawaii, Honolulu, HI, US; [2]Kaiser Permanente, Honolulu, HI, US

755 TMAO and HIV-Associated Atherosclerosis

Arjun Sinha[1]; Yifei Ma[1]; Rebecca Scherzer[2]; Courtney Carroll[1]; Steven Deeks[3]; Peter Ganz[1]; Priscilla Hsue[1]

[1]San Francisco General Hospital, San Francisco, CA, US; [2]San Francisco VA Medical Center, San Francisco, CA, US; [3]University of California San Francisco, San Francisco, CA, US

756 Impaired Cardiac Strain and Biomarkers of Immune Activation in HIV

Colleen Hadigan[1]; **Julia Purdy**[1]; Diana Thiara[1]; Louisa Howard[1]; Chia-Ying Liu[1]; Fabio Raman[1]; Sabrina Mangat[1]; Christopher Sibley[2]; David Bluemke[1]

[1]National Institutes of Health (NIH), Bethesda, MD, US; [2]Oregon Health and Sciences University, Portland, OR, US

Session P-P7 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Endothelial Functions and Cerebral Vasoreactivity

757 Role of Angiopoietin 1, Angiopoietin 2, and Endothelial Function in HIV

Mark L. Dela Cruz[1]; Yifei Ma[1]; Rebecca Scherzer[1]; Alan Wu[2]; Kristinalisa Maka[1]; Steven Deeks[1]; Peter Ganz[1]; Priscilla Hsue[1]

[1]University of California San Francisco, San Francisco, CA, US; [2]Blood Systems Research Institute/ University of California San Francisco, San Francisco, CA, US

758 HIV-Infected Persons With Type 2 Diabetes Have Evidence of Endothelial Dysfunction

Malene Hove[1]; Julie C. Gaardbo[3]; Hedda Hoel[3]; Lillian Kolte[2]; Allan Vaag[1]; Jan Gerstoft[1]; Henrik Ullum[1]; Marius Troseid[3]; Susanne D. Poulsen[1]

[1]Rigshospitalet, University Hospital of Copenhagen, Copenhagen, Denmark; [2]Hvidovre Hospital, University Hospital of Copenhagen, Hvidovre, Denmark; [3]Oslo University Hospital, Ullevål, Norway

759 Unique Circulating MicroRNA Profiles and Endothelial Function in HIV Infection

Venkata A. Narla[1]; Nirav Bhakta[2]; Jane E. Freedman[3]; Kahraman Tanriverdi[3]; Kristinalisa Maka[1]; Steven Deeks[2]; Peter Ganz[1]; Priscilla Hsue[1]

[1]San Francisco General Hospital, University of California San Francisco, San Francisco, CA, US; [2]University of California San Francisco, San Francisco, CA, US; [3]University of Massachusetts Medical School, Worcester, MA, US

760 Cerebral Vasoreactivity Is Impaired in Virally Suppressed HIV-Infected Individuals

Felicia C. Chow[1]; Claire Mills[1]; Nerissa Ko[1]; Courtney Carroll[1]; Richard Price[1]; Steven Deeks[1]; Farzaneh A. Sorond[2]; Priscilla Y. Hsue[1]

[1]University of California San Francisco, San Francisco, CA, US; [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, US

Session P-Q1 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Inflammation: Biomarkers and Relationship to Outcomes

761 IL-6 Is a Stronger Predictor of Clinical Events Than hsCRP or D-Dimer in HIV Disease

Álvaro H. Borges[1]; Jemma L. O'Connor[2]; Andrew N. Phillips[2]; James D. Neaton[3]; Birgit Grund[4]; Jacqueline Neuhaus[3]; Michael Vjecha[7]; Alexandra Calmy[5]; Kersten K. Koelsch[6]; Jens D. Lundgren[1]

INSIGHT SMART and ESPRIT Study Groups

[1]Rigshospitalet, University of Copenhagen, Copenhagen, Denmark; [2]University College London, London, United Kingdom; [3]University of Minnesota, Minneapolis, MN, US; [4]University of Minnesota, Minneapolis, MN, US; [5]Geneva University Hospitals, Geneva, Switzerland; [6]University of New South Wales, Sydney, Australia; [7]Veterans Affairs Medical Center, Washington, DC, US

762 Persistent Inflammation on ART Is Associated With Poor Nutritional Recovery in Zambia

George Praygod[2]; Meridith Blevins[1]; Susannah Woodd[3]; Andrea Rehman[3]; Jeremiah Kidola[2]; Henrik Friis[4]; Paul Kelly[5]; Douglas Heimburger[1]; Suzanne Filteau[3]; **John Koethe**[1]

[1]Vanderbilt University, Nashville, TN, US; [2]National Institute of Medical Research, Mwanza, United Republic of Tanzania; [3]London School of Hygiene & Tropical Medicine, London, United Kingdom; [4]University of Copenhagen, Copenhagen, Denmark; [5]University Teaching Hospital, Lusaka, Zambia

763 Smoking and Obesity May Partially Explain the Inflammation and Morbidity Association

Supriya Krishnan[1]; Ronald Bosch[1]; Benigno Rodriguez[2]; Peter W. Hunt[3]; Cara C. Wilson[4]; Steven Deeks[3]; Michael M Lederman[2]; Alan Landay[5]; Carey Lumeng[6]; Allan Tenorio[7]

[1]Center for Biostatistics in AIDS Research, Harvard School of Public Health, Boston, MA, US; [2]Division of Infectious Diseases and HIV Medicine, Case Western Reserve University School of Medicine, Cleveland, OH, US; [3]Positive Health Program, Dept of Medicine, San Francisco General Hospital, San Francisco, CA, US; [4]Division of Infectious Diseases, Univ of Colorado Hospital, Aurora, CO, US; [5]Department of Immunology and Microbiology, Rush Univ Medical Center, Chicago, IL, US; [6]Univ of Michigan Medical School, Department of Pediatrics, Ann Arbor, MI, US; [7]Department of Medicine, Rush University Medical Center, Chicago, IL, US

764 Infectious and Noninfectious Multimorbidity Among HIV Clinic Clients in the African Cohort Study

Julie Ake[1]; Jonah Maswai[2]; Francis Kiweewa[3]; Lucas Maganga[4]; Milton Omondi[5]; Babajide Keshinro[6]; Lindsay Hughes[1]; Victor G. Valcour[7]; Christina Polyak[1]

RV 329 AFRICOS Study Team

[1]US Military HIV Research Program, Bethesda, MD, US; [2]KEMRI/Walter Reed Project, Kericho, Kenya; [3]Makerere University Walter Reed Project, Kampala, Uganda; [4]Mbeya Medical Research Centre, Mbeya, United Republic of Tanzania; [5]KEMRI/Walter Reed Project, Kisumu, Kenya; [6]Walter Reed Program - Nigeria, Abuja, Nigeria; [7]University of California San Francisco (UCSF), San Francisco, CA, US

Session P-Q2 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Bone Metabolism and ART: Mechanisms and Outcomes

765 Bone Metabolism and Tenofovir: Evidence of Direct Effect on Calcium-Sensing Receptor

Paolo Bonfanti[2]; Caterina Brasacchio[3]; Chiara Molteni[2]; Barbara Menzaghi[1]; Laura Soldati[3]; Tiziana Quirino[1]; Stefano Mora[4]

[1]Busto Arsizio Hospital, Busto Arsizio, Italy; [2]A. Manzoni Lecco Hospital, Lecco, Italy; [3]Department of Health Sciences, University of Milan, Milan, Italy; [4]San Raffaele Scientific Institute, Milan, Italy

766 Bone Turnover on DRV/r + Either RAL or TDF/FTC as First-Line ART: NEAT 001 / ANRS 143

Jose I Bernardino[1]; Amanda Mocroft[2]; Laura Richert[3]; Abdel Babiker[4]; Antonio Buño[1]; Antonella Castagna[5]; Pierre-Marie Girard[6]; Genevieve Chene[3]; Jose R Arribas[1]; François Raffi[7]

[1]Hospital Universitario La Paz. IdiPAZ, Madrid, Spain; [2]University College London, London, United Kingdom; [3]University of Bordeaux, Bordeaux, France; [4]MRC Clinical Trials Unit at University College London, London, United Kingdom; [5]San Raffaele Scientific Institute, Milan, Italy; [6]Hospital St Antoine and Inserm, Paris, France; [7]Université Nantes, Nantes, France

767 Tenofovir Replacement in Patients With Osteoporosis Increased Sclerostin Levels

Eugenia Negredo[3]; Adolfo Díez-Pérez[2]; Pere Domingo[4]; Nuria Pérez-Álvarez[6]; Mar Gutierrez[4]; Gracia Mateo[4]; Jordi Puig[1]; Patricia Echeverria[1]; Anna Bonjoch[1]; Bonaventura Clotet[5]

[1]LLuita Contra la Sida Foundation, Germans Trias i Pujol University Hospital, Universitat Autònoma de Barcelona, Barcelona, Spain; [2]Hospital del Mar-IMIM, Universitat Autònoma de Barcelona and RETICEF, Instituto Carlos III Madrid, Barcelona, Spain; [3]LLuita Contra la Sida Foundation, Germans Trias i Pujol University Hospital, Universitat Autònoma de Barcelona, Universitat de Vic–Universitat Central de Catalunya, Barcelona, Spain; [4]Santa Creu i Sant Pau Hospital, Universitat Autònoma de Barcelona, Barcelona, Spain; [5]LLuita Contra la Sida Foundation, Germans Trias i Pujol University Hospital, Universitat Autònoma de Barcelona, Irsicaixa Foundation, Germans Trias i Pujol University Hospital, Barcelona, Spain; [6]LLuita Contra la Sida Foundation, Germans Trias i Pujol University Hospital, Universitat Autònoma de Barcelona, Statistics and Operations Research Department, Universitat Politècnica de Catalunya, Barcelona, Spain

768 Relationship Between Phosphate Reabsorption, Age, Tenofovir and Bone Mineral Density

Lisa Hamzah[2]; **Amanda Samarawickrama**[1]; Karen Walker-Bone[3]; Yvonne Gilleece[4]; Martin Fisher[1]; Frank A. Post[5]

[1]Brighton and Sussex Medical School, London, United Kingdom; [2]King's College London, London, United Kingdom; [3]University of Southampton, Southampton, United Kingdom; [4]Brighton and Sussex Hospitals NHS Trust, Brighton, United Kingdom; [5]King's College Hospital NHS Foundation Trust, London, United Kingdom

769LB Less Bone Loss With a Maraviroc Regimen in HIV-Infected Treatment-Naïve Subjects

Babafemi Taiwo[1]; Ellen Chan[2]; Carl Fichtenbaum[3]; Heather Ribaudo[2]; Athe Tsibris[4]; Karin Klingman[5]; Joseph J. Eron[6]; Baiba Berzins[1]; Todd T. Brown[7]
ACTG A5303 Study Team

[1]Northwestern University, Feinberg School of Medicine, Chicago, IL, US; [2]Statistical and Data Analysis Center, Harvard School of Public Health, Boston, MA, US; [3]University of Cincinnati, Cincinnati, OH, US; [4]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, US; [5]National Institutes of Health, Bethesda, MD, US; [6]University of North Carolina at Chapel Hill, Chapel Hill, NC, US; [7]Johns Hopkins University School of Medicine, Baltimore, MD, US

Session P-Q3 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Bone Disease: Mechanisms of Bone Loss and Fracture Risk

770 Association of Adipokines With Bone Mineral Density in HIV+ and HIV- Women

Anjali Sharma[1]; Yifei Ma[2]; Rebecca Scherzer[2]; Amber L. Wheeler[2]; Mardge Cohen[3]; Deborah Gustafson[4]; Michael T Yin[5]; Phyllis C. Tien[2]

[1]Albert Einstein College of Medicine, Bronx, NY, US; [2]University of California San Francisco, San Francisco, CA, US; [3]John H. Stroger Jr. Hospital of Cook County, Chicago, IL, US; [4]State University of New York Downstate Medical Center, Brooklyn, NY, US; [5]College of Physicians and Surgeons, Columbia University, New York, NY, US

771 Long-Term Changes in Bone Mineral Density and Insulin Resistance on Statins in HIV

Kristine M. Erlandson[1]; Ying Jiang[2]; Sara M. Debanne[2]; Grace A. McComsey[2]

[1]University of Colorado, Aurora, CO, US; [2]Case Western Reserve University, Cleveland, OH, US

772 Immunologic Predictors of Bone Loss in a Contemporary HIV Cohort

Edgar T. Overton[1]; Katherine H. Hullsiek[2]; Gerome Escota[3]; Kenneth A. Lichtenstein[4]; Lois Conley[5]; Pragna Patel[5]; John T. Brooks[5]; Irini Sereti[6]; Jason V. Baker[2]
the CDC SUN (Study to Understand the Natural History of HIV/AIDS in the Era of Effective Therapy) Investigators

[1]University of Alabama at Birmingham, Birmingham, AL, US; [2]University of Minnesota, Minneapolis, MN, US; [3]Washington University School of Medicine, St. Louis, MO, US; [4]National Jewish Health, Denver, CO, US; [5]Division of HIV/AIDS Prevention, Atlanta, GA, US; [6]National Institute of Allergy and Infectious Disease (NIAID), Bethesda, MD, US

773 RANKL Predicts 96-Week BMD Changes in ATV/r Monotherapy: A MODAt Trial Sub-Study

Vincenzo Spagnuolo[1]; Marco Borderi[2]; Giuseppina Musumeci[2]; Laura Galli[1]; Camilla Tincati[3]; Stefano Rusconi[3]; Giovanni Guaraldi[4]; Alba Bigoloni[1]; Adriano Lazzarin[1]; Antonella Castagna[1]

[1]San Raffaele Scientific Institute, Milan, Italy; [2]Alma Mater Studiorum University of Bologna, Bologna, Italy; [3]University of Milan, Milan, Italy; [4]University of Modena and Reggio Emilia, Modena, Italy

774 Predictors of Longitudinal Change in Bone Mineral Density in a Cohort of HIV Positive and Negative Subjects

Willard Tinago[1]; Aoife Cotter[1]; Caroline Sabin[2]; Alan Macken[1]; Eoin Kavanagh[3]; Jennifer Brady[4]; Geraldine McCarthy[5]; Juliet Compston[6]; Patrick W. Mallon[1]
HIV UPBEAT Study Group

[1]University College Dublin, Dublin, Ireland; [2]Research Department of Infection and Poulation Health, London, United Kingdom; [3]Mater Misericordiae University Hospital, Dublin, Ireland; [4]Mater Misericordiae University Hospital, Dublin, Ireland; [5]Mater Misericordiae University Hospital, Dublin, Ireland; [6]University of Cambridge, London, United Kingdom

775 Fracture Incidence Is Increased in Aging HIV-Infected Women

Anjali Sharma[1]; Qiuhu Shi[2]; Donald R. Hoover[3]; Kathryn Anastos[1]; Phyllis C. Tien[4]; Mary A. Young[5]; Mardge Cohen[6]; Deborah Gustafson[7]; Michael T Yin[8]

[1]Albert Einstein College of Medicine, Bronx, NY, US; [2]New York Medical College, Valhalla, NY, US; [3]Rutgers University, Piscataway, NJ, US; [4]University of California San Francisco, San Francisco, CA, US; [5]Georgetown University, Washington D.C., DC, US; [6]John H. Stroger Jr. Hospital of Cook County, Chicago, IL, US; [7]State University of New York Downstate Medical Center, Brooklyn, NY, US; [8]College of Physicians and Surgeons, Columbia University, New York, NY, US

Session P-Q4 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Measuring Bone Density

776 Heel Quantitative Ultrasound to Cut Down on DXA Costs in HIV-infected Patients

Marilia R. Pinzone; Maria Gussio; Daniela Castronuovo; Adriana Di Gregorio; Benedetto M. Celesia; Bruno Cacopardo; Giuseppe Nunnari

University of Catania, Catania, Italy

777 Novel Radiographic Measures HRpQCT and HSA as Correlates of HIV-Associated Fractures

Darrell H. Tan[1]; Janet Raboud[2]; Leah Szadkowski[2]; Eva Szabo[4]; Hanxian Hu[4]; Queenie Wong[4]; Angela Cheung[4]; Sharon Walmsley[3]

[1]St. Michael's Hospital, Toronto, Canada; [2]Toronto General Research Institute, Toronto, Canada; [3]University Health Network, Toronto, Canada; [4]Centre for Excellence in Skeletal Health Assessment, Toronto, Canada

WEDNESDAY, FEBRUARY 25, 2015

Session P-Q5 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Fat Without Borders: Metabolic Complications in Resource-Limited Settings

778 Obesity and Inflammation in Resource-Diverse Settings of ART Initiation

Kristine M. Erlandson[1]; Nikhil Gupte[2]; Javier R. Lama[3]; Patcharaphan Sugandhavesa[4]; Thando Mwelase[5]; Ashwin Balagopal[2]; David Asmuth[6]; Thomas B. Campbell[1]; Amita Gupta[2]
On behalf of the A5175 and NWCS319 study team

[1]University of Colorado, Aurora, CO, US; [2]Johns Hopkins University, Baltimore, MD, US; [3]Impacta Peru Clinical Trials Unit, Lima, Peru; [4]Chiang Mai University, Chiang Mai, Thailand; [5]University of Witswatersrand, Johannesburg, South Africa; [6]University of California Davis, Sacramento, CA, US

779 Body Composition Outcomes at 96 Weeks in the SECOND-LINE RCT DXA Substudy

Mark A. Boyd[1]; Janaki Amin[1]; Patrick W. Mallon[2]; Jennifer F. Hoy[3]; Samuel Ferret[4]; Waldo Belloso[5]; Praphan Phanuphak[6]; Sean Emery[1]; David A. Cooper[1]
SECOND-LINE study group

[1]University of New South Wales Australia, Sydney, Australia; [2]University College Dublin, Dublin, Ireland; [3]Monash University/Alfred Hospital, Melbourne, Australia; [4]Hopital Saint Louis, Paris, France; [5]Hospital Italiano, Buenos Aires, Argentina; [6]Thai Red Cross AIDS Research Centre, Bangkok, Thailand

780 Bone Quality by Quantitative Ultrasound at the Radius Does Not Differ in ART-Naïve HIV+ and HIV- Rwandan Women

Eugene Mutimura[1]; Qiuhu Shi[2]; Donald R. Hoover[3]; Kathryn Anastos[4]; Emmanuel Rudakemwa[5]; Jean Claude Dusingize[1]; Jean D'Amour Sinayobye[1]; Michael T Yin[6]

[1]Regional Alliance for Sustainable Development, Kigali, Rwanda; [2]School of Health Sciences and Practice, New York Medical College, New York, NY, US; [3]State University of New Jersey, New Brunswick, NJ, US; [4]Albert Einstein College of Medicine and Montefiore Medical Center, Bronx, NY, US; [5]King Faisal Hospital, Kigali, Rwanda; [6]Columbia University Medical Center, New York, NY, US

781 Predictors and Outcomes of Incident High Cholesterol in Adults on ART in South Africa

Denise Evans[1]; Alana T. Brennan[2]; Faith Moyo[1]; David Spencer[3]; Kay Mahomed[3]; Mhairi Maskew[1]; Lawrence Long[1]; Sydney Rosen[2]; **Matt P. Fox**[2]

[1]University of the Witwatersrand, Johannesburg, South Africa; [2]Boston University, Boston, MA, US; [3]Right to Care, Johannesburg, South Africa

782 Metabolic Changes and Second-Line ART in Africa (2LADY/ANRS 12169 Trial)

Amandine Cournil[1]; Assane Diouf[3]; Sabrina Eymard-Duvernay[1]; Adrien Sawadogo[2]; Liliane Ayangma[4]; Louise Fortes-Deguenonvo[3]; Jean-Marc Mben[6]; Eric Delaporte[1]; Laura Ciaffi[1]; Sinata Koulla-Shiro[5]

[1]IRD/UM 1, Montpellier, France; [2]CHU Souro Sanou, Bobo Dioulasso, Burkina Faso; [3]CRCF, Dakar, Senegal; [4]Yaounde Military Hospital, Yaounde, Cameroon; [5]FMSB/University Yaounde 1, Yaounde, Cameroon; [6]ANRS Research Center, Yaounde, Cameroon

TUESDAY, FEBRUARY 24, 2015

Session P-Q6 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Aging: Frailty, Telomeres, and mtDNA

783 Frailty and Cause-Specific Hospitalization Among Persons Aging With HIV and Drug Use

Damani A. Piggott[1]; Abimereki D. Muzaale[1]; Shruti H. Mehta[1]; Ryan P. Westergaard[2]; Todd T. Brown[1]; Kushang V. Patel[3]; Sean X. Leng[1]; Gregory D. Kirk[1]

[1]Johns Hopkins University, Baltimore, MD, US; [2]University of Wisconsin, Madison, WI, US; [3]University of Washington, Seattle, WA, US

784 Association of HIV Viral Load and Shorter Telomere Length

Shawn Gogia; Jue Lin; Yifei Ma; Rebecca Scherzer; Elizabeth Blackburn; Ramin Farzaneh-Far; Steven Deeks; Priscilla Hsue

University of California San Francisco, San Francisco, CA, US

785 Novel Mechanisms of Nucleoside Analog Associated Mitochondrial DNA Mutation

Kristian Gardner; Patrick F. Chinnery; **Brendan A. Payne**

Newcastle University, Newcastle-upon-Tyne, United Kingdom

786 Balance Confidence Predicts Falls Better Than Physical Function Testing in HIV+ Men

Todd T. Brown[1]; Xiuhong Li[2]; Lisa P. Jacobson[2]; Jennifer Schrack[2]; Frank J. Palella[3]; Lawrence Kingsley[4]; Joseph B. Margolick[2]; Adrian Dobs[1]; Jordan Lake[5]; Keri N. Althoff[2]
MACS

[1]Johns Hopkins University School of Medicine, Baltimore, MD, US; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [3]Northwestern University, Feinberg School of Medicine, Chicago, IL, US; [4]University of Pittsburgh, Pittsburgh, PA, US; [5]University of California Los Angeles, Los Angeles, CA, US

Session P-Q7 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Diabetes and Other Endocrine Disorders

787 Vitamin D Supplementation Does Not Affect Metabolic Changes Seen With ART Initiation

Todd T. Brown[1]; Ellen Chan[2]; Edgar T. Overton[3]; Pablo Tebas[4]; Kathy Melbourne[5]; Royce Hardin[6]; Heather Ribaudo[2]; Michael T. Yin[7]
ACTG

[1]Johns Hopkins University School of Medicine, Baltimore, MD, US; [2]Harvard School of Public Health, Center for Biostatistics in AIDS Research, Boston, MA, US; [3]University of Alabama at Birmingham, Birmingham, AL, US; [4]University of Pennsylvania, Philiadelphia, PA, US; [5]Gilead Sciences, Inc., Foster City, CA, US; [6]Duke University, Durham, NC, US; [7]College of Physicians and Surgeons, Columbia University, New York, NY, US

788 First-Line NRTIs and Risk of New Onset Diabetes in HIV-Infected Adults in Thailand

Prakit Riyaten[1]; Nicolas Salvadori[2]; Patrinee Traisathit[1]; Nicole Ngo-Giang-Huong[2]; Rapeepan Suaysod[2]; Guttiga Halue[3]; Naruepon Yutthakasemsunt[4]; Apichat Chutanunta[5]; Jacqueline Capeau[6]; Gonzague Jourdain[2]

[1]Chiang Mai University, Chiang Mai, Thailand; [2]Institut de Recherche Pour le Développement UMI 174-PHPT, Chiang Mai, Thailand; [3]Phayao Provincial Hospital, Phayao, Thailand; [4]Nong Khai Hospital, Nong Khai, Thailand; [5]Samutsakhon Hospital, Samutsakhon, Thailand; [6]Sorbonne University, Paris, France

789 Diabetes Mellitus Among HIV-Infected Adults in Care in the United States, 2009–2010

Alfonso C. Hernandez-Romieu

Emory University Rollins School of Public Health, Decatur, GA, US

790 Functional Vitamin D Deficiency With Initiation of Tenofovir-Based ART?

Evelyn Hsieh[1]; Liana Fraenkel[1]; Weibo Xia[2]; Yang Han[2]; Michael T Yin[3]; Karl Insogna[4]; Ting Zhu[2]; Taisheng Li[2]

[1]Yale University School of Medicine, New Haven, CT, US; [2]Peking Union Medical College Hospital, Beijing, China; [3]Columbia University Medical Center, New York, NY, US; [4]Yale University School of Medicine, New Haven, CT, US

791 Determinants of Parathyroid Hormone Levels in HIV-positive Tenofovir-treated Patients with Normal Renal Function

Letizia Marinaro; Andrea Calcagno; Jessica Cusato; Elisabetta Scarvaglieri; Marco Simiele; Maria Cristina Tettoni; Laura Trentini; Antonio D'Avolio; Giovanni Di Perri; Stefano Bonora

Unit of Infectious Diseases, Turin, Italy

THURSDAY, FEBRUARY 26, 2015

Session P-Q8 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Renal Dysfunction: ART and Biomarkers

792 Elevated Tenofovir Exposure via Intensive PK Monitoring Is Associated With Progressive Kidney Function Decline

Sanjiv M. Baxi[1]; Rebecca Scherzer[1]; Ruth M. Greenblatt[1]; Howard Minkoff[2]; Kathryn Anastos[5]; Mardge H. Cohen[4]; Mary A. Young[3]; Monica Gandhi[1]; Michael G. Shlipak[1]

[1]University of California San Francisco, San Francisco, CA, US; [2]State University of New York Downstate Medical Center, Brooklyn, NY, US; [3]Georgetown University, Washington, DC, US; [4]John Stroger (formerly Cook County) Hospital, Chicago, IL, US; [5]Montefiore Medical Center, University Hospital for Albert Einstein College of Medicine, Bronx, NY, US

793 Impact of TDF+PI/r on Renal Function in Sub-Saharan Africa : 2LADY/ANRS 12169 Trial

Arsene Hema[1]; **Amandine Cournil**[2]; Laura Ciaffi[2]; Sabrina Eymard-Duvernay[2]; Assane Diouf[3]; Nestor Manga[4]; Vincent Le Moing[2]; Jacques Reynes[2]; Sinata Koulla-Shiro[5]; Eric Delaporte[2]

[1]CHU Souro Sanou, Bobo Dioulasso, Burkina Faso; [2]IRD/UM 1, Montpellier, France; [3]Le Centre Régional de Recherche et de Formation à la Prise en Charge Clinique de Fann, Dakar, Senegal; [4]Yaounde Military Hospital, Yaounde, Cameroon; [5]FMSB/University Yaounde 1, Yaounde, Cameroon

794 Renal Tubular Disease and the Relationship With Tenofovir and Atazanavir Exposure

Lisa Hamzah[1]; John Booth[2]; Catherine Horsfield[3]; Rachael Jones[4]; Jeremy Levy[5]; Deborah Williams[6]; Nadia Khatib[7]; Rachel Hilton[3]; John Connolly[2]; Frank A. Post[8]

[1]King's College London, London, United Kingdom; [2]University College London, London, United Kingdom; [3]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; [4]Chelsea and Westminster Hospital, NHS Foundation Trust, London, United Kingdom; [5]Imperial College London, London, United Kingdom; [6]Brighton and Sussex Hospitals NHS Trust, London, United Kingdom; [7]Heart of England NHS Foundation Trust, Birmingham, United Kingdom; [8]King's College Hospital NHS Foundation Trust, London, United Kingdom

795 Safety of Tenofovir Alafenamide in Renal Impairment

Anton Pozniak[2]; Jose R Arribas[3]; Samir K. Gupta[4]; Frank A. Post[5]; Anchalee Avihingsanon[6]; Gordon Crofoot[7]; Kenneth A. Lichtenstein[8]; Moti Ramgopal[9]; Ploenchan Chetchotisakd[10]; **Marshall W. Fordyce**[1]

[1]Gilead Sciences Inc, Foster City, CA, US; [2]Chelsea and Westminster Hospital NHS Foundation Trust, London, United Kingdom; [3]Hospital Universitario La Paz, Madrid, Spain; [4]Indiana University School of Medicine, Indianapolis, IN, US; [5]King's College Hospital NHS Foundation Trust, London, United Kingdom; [6]HIV-NAT, Thai Red Cross AIDS Research Center and Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [7]Crofoot Research, Houston, TX, US; [8]National Jewish Health, Denver, CO, US; [9]Midway Research Center, Ft. Pierce, FL, US; [10]Khon Kaen University, Khon Kaen, Thailand

796 Elevated Nonclassical Monocytes and Urine Fibrotic Markers in HIV Albuminuria

Brooks I. Mitchell; Mary Margeret Byron; Roland C. Ng; Dominic C. Chow; Pichaya O-charoen; Lishomwa C. Ndhlovu; Cecilia M. Shikuma

University of Hawaii, Honolulu, HI, US

797 Kidney Dysfunction and Markers of Inflammation in the Multicenter AIDS Cohort Study

Alison G. Abraham[1]; Annie Darilay[2]; Heather McKay[1]; Joseph B. Margolick[1]; Michelle M. Estrella[3]; Frank J. Palella[4]; Robert Bolan[5]; Charles R. Rinaldo[6]; Lisa P. Jacobson[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [2]AstraZeneca, Gaithersburg, MD, US; [3]Johns Hopkins University School of Medicine, Baltimore, MD, US; [4]Northwestern University, Feinberg School of Medicine, Chicago, IL, US; [5]Los Angeles LGBT Center, Los Angeles, CA, US; [6]University of Pittsburgh, Pittsburgh, PA, US

Session P-Q9 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Renal Transplantation: Long-Term Outcomes

798 Risk Factors for Acute Allograft Rejection in HIV Positive Kidney Transplant Recipients

Esther N. Gathogo[1]; Mark Harber[2]; Sanjay R. Bhagani[2]; Joanne Baxter[3]; Vincent Lee[4]; Jeremy Levy[5]; Rachael Jones[6]; Rachel Hilton[7]; Graham Davies[1]; Frank A. Post[1]

[1]King's College London, London, United Kingdom; [2]Royal Free London NHS Foundation Trust, London, United Kingdom; [3]North Manchester General Hospital, Manchester, United Kingdom; [4]Central Manchester University Hospitals, Manchester, United Kingdom; [5]Imperial College Healthcare NHS Trust, London, United Kingdom; [6]Chelsea and Westminster Hospital, NHS Foundation Trust, London, United Kingdom; [7]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom

799 Survival in HIV-Positive Transplant Recipients Compared to Matched Registry Controls

Michelle E. Roland[1]; Burc Barin[2]; Shirish Huprikar[3]; **Michael Wong**[4]; Emily Blumberg[5]; David Simon[6]; Margaret Ragni[7]; Don Stablein[2]; Peter Stock[1]
HIV-TR Study Team

[1]University of California San Francisco, San Francisco, CA, US; [2]EMMES Corporation, Rockville, MD, US; [3]Mount Sinai School of Medicine, New York, NY, US; [4]Beth Israel Deaconess Medical Center, Boston, MA, US; [5]University of Pennsylvania, Philadephia, PA, US; [6]Rush University Medical Center, Chicago, IL, US; [7]University of Pittsburgh, Pittsburgh, PA, US

Session P-Q10 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Pulmonary Disease

800 Risk Factors for Airflow Obstruction Among HIV+ Individuals in Nairobi, Kenya

Engi F. Attia[1]; Elizabeth Maleche-Obimbo[2]; Nelly Yatich[1]; Lillian Ndukwe[3]; Julia Njoroge[3]; Sameh Sakr[3]; Neveen El Antouny[3]; Fr. Mena Attwa[3]; Kristina Crothers[1]; Michael Chung[1]

[1]University of Washington, Seattle, WA, US; [2]University of Nairobi, Nairobi, Kenya; [3]Coptic Hope Center for Infectious Diseases, Nairobi, Kenya

801 Pulmonary Complications of HIV-1 in Youth: The PHACS AMP Study

William T. Shearer[1]; Erin Leister[2]; George Siberry[3]; Denise L. Jacobson[2]; Russell B. Van Dyke[4]; Hannah H. Peavy[5]; Suzanne Siminski[6]; Meyer Kattan[7]; Laurie Butler[6]; Andrew Colin[8]

[1]Baylor College of Medicine and Texas Children's Hospital, Houston, TX, US; [2]Harvard School of Public Health, Boston, MA, US; [3]National Institutes of Health (NIH), Bethesda, MD, US; [4]Tulane University Health Sciences Center, New Orleans, LA, US; [5]National Heart, Lung, and Blood Institute, Bethesda, MD, US; [6]Frontier Science and Technology Research Foundation, Amherst, NY, US; [7]Columbia University Medical Center, New York, NY, US; [8]University of Miami Health System Batchelor Research Institute, Miami, FL, US

802 Distinct Airway Methylation and Gene Expression Profiles in HIV-Associated COPD

Janice M. Leung[1]; Emily Vucic[2]; Joseph C. Liu[1]; David Ngan[1]; Tawimas Shaipanich[3]; Julio Montaner[4]; Stephen Lam[2]; Don Sin[1]; Wan Lam[2]; S. F. Paul Man[1]

[1]Centre for Heart Lung Innovation, Vancouver, Canada; [2]BC Cancer Research Center, Vancouver, Canada; [3]St. Paul's Hospital, Vancouver, Canada; [4]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada

Session P-Q11 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Body Composition and Risk Factors for Abnormalities

803 Altered Body Composition and Inflammation in HIV Infection With Type 2 Diabetes

Malene Hove; Julie Abildgaard; Julie C. Gaardbo; Allan Vaag; Jan Gerstoft; Bente Klarlund Pedersen; Birgitte Lindegaard; Susanne D. Poulsen

Rigshospitalet, University Hospital of Copenhagen, Copenhagen, Denmark

804 Alcohol, Substance Use, and Smoking Associations With Lipoatrophy and Lipohypertrophy

Marisela Noorhasan[1]; Daniel R. Drozd[1]; Aaron Blashill[2]; Greer Burkholder[3]; Karen Cropsey[3]; Matthew Mimiaga[2]; Katerina Christopoulos[4]; Carl Grunfeld[4]; **Heidi M. Crane**[1]
Centers for AIDS Research Network of Integrated Clinical Systems

[1]University of Washington, Seattle, WA, US; [2]Harvard Medical School, Boston, MA, US; [3]University of Alabama at Birmingham, Birmingham, AL, US; [4]University of California San Francisco, San Francisco, CA, US

Session P-Q12 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Complications: Liver Disease Without Viral Hepatitis

805 Antiretroviral Drugs Associated With Chronic ALT Elevations in Persons Without HCV and HBV Infection

Helen Kovari[1]; Caroline Sabin[2]; Bruno Ledergerber[1]; Lene Ryom[3]; Antonella d'Arminio Monforte[4]; Matthew G. Law[5]; Stéphane De Wit[6]; Andrew N. Phillips[2]; Jens D. Lundgren[3]; Rainer Weber[1]
on behalf of the D:A:D Study Group

[1]University Hospital Zurich, Zurich, Switzerland; [2]University College London, London, United Kingdom; [3]University of Copenhagen, Copenhagen, Denmark; [4]University of Milan, Milan, Italy; [5]University of New South Wales, Sydney, Australia; [6]St Pierre University Hospital, Brussels, Belgium

806 APRI and FIB4: Associated With D-Drug Exposure, Low CD4 Count and Monocyte Activation

Katherine W. Kooij[1]; Rosan van Zoest[1]; Ferdinand W. Wit[1]; Judith Schouten[2]; Neeltje Kootstra[2]; Ineke G. Stolte[3]; Maria Prins[3]; Peter Reiss[1]; Marc van der Valk[2]
AGEhIV Cohort Study Group

[1]Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands; [2]Academic Medical Center University of Amsterdam, Amsterdam, Netherlands; [3]Public Health Service of Amsterdam, Amsterdam, Netherlands

807 HIV and Liver Fibrosis Among Prison Inmates: The IeDEA West Africa Collaboration

Antoine Jaquet[1]; Gilles Wandeler[2]; Judicael Tine[3]; Claver Dagnra[4]; Alain Attia[5]; Akouda Patassi[6]; Abdoulaye Ndiaye[7]; Koumavi K. Ekouevi[8]; Moussa Seydi[3]; François Dabis[1]

[1]Inserm U897, ISPED, Université de Bordeaux, Bordeaux, France; [2]Department of Infectious Diseases, Bern University Hospital, Bern, Switzerland; [3]Service de Maladies Infectieuses et Tropicales, CRCF, CHU de Fann, Dakar, Senegal; [4]Service de Virologie, BIOLIM, Université de Lomé, Lomé, Togo; [5]Service de Hépato-Gastroentérologie, CHU de Yopougon, Abidjan, Côte d'Ivoire; [6]Service de Maladies Infectieuses et Tropicales, CHU Sylvanus Olympio, Lomé, Togo; [7]Service de Médecine Interne, CHU Aristide Le Dantec, Dakar, Senegal; [8]Département de Santé Publique, Faculté des Sciences de la Santé, Université de Lomé, Lomé, Togo

Session P-Q13 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Depression and Alcohol Use Disorders

808 Clinical Correlates of Alcohol Use Disorders Among HIV-Infected Adults in Zambia

Michael J. Vinikoor[1]; Masumba Masaninga[2]; Carolyn Bolton Moore[3]; Virginia Munamununungu[4]; Alice Siyunda[4]; Lloyd Mulenga[5]; Matthias Egger[6]; Benjamin H. Chi[3]; Gilles Wandeler[6]
IeDEA Southern Africa

[1]University of North Carolina, Lusaka, Zambia; [2]Lusaka District Health Management Team, Lusaka, Zambia; [3]University of North Carolina, Chapel Hill, NC, US; [4]Centre for Infectious Disease Research in Zambia, Lusaka, Zambia; [5]University of Zambia, Lusaka, Zambia; [6]Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland

809 Depression and Treatment Outcomes Among Tanzanian Adults Initiating HAART

Christopher R. Sudfeld[1]; Sylvia Kaaya[2]; Nilupa S. Gunaratna[1]; Wafaie Fawzi[1]; Ferdinand Mugusi[2]; Mary C. Smith Fawzi[3]

[1]Harvard School of Public Health, Roxbury Crossing, MA, US; [2]Muhimbili University of Health and Allied Sciences, Dar es Salaam, United Republic of Tanzania; [3]Harvard Medical School, Boston, MA, US

TUESDAY, FEBRUARY 24, 2015

Session P-R1 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Immune Reconstitution Inflammatory Syndrome in Opportunistic Infections

810 Discordant Early Immune Responses Distinguish TB IRIS and Death in HIV/TB Coinfection

Shruthi Ravimohan[1]; Neo Tamuhla[2]; Andrew Steenhoff[2]; Rona Letlhogile[2]; Kebatshabile Nfanyana[2]; Tumelo Rantleru[2]; Robert Gross[1]; Drew Weissman[1]; Gregory P. Bisson[1]

[1]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, US; [2]Botswana University of Pennsylvania Partnership, Gaborone, Botswana

811 WITHDRAWN

812 Exuberant Pathogen-Specific Th1 CD4+ T-Cell Responses in MAC-IRIS in HIV Infection

Kimberly F. Faldetta[1]; Denise C. Hsu[1]; Virginia Sheikh[1]; Gregg Roby[2]; Kenneth Olivier[1]; Irini Sereti[1]

[1]National Institutes of Health (NIH), Rockville, MD, US; [2]National Institutes of Health (NIH), Bethesda, MD, US

813 A Paradoxical Treatment of Mycobacterial Immune Reconstitution Inflammatory Syndrome

Denise C. Hsu; Kimberly F. Faldetta; **Luxin Pei**; Delmyra Turpin; Virginia Sheikh; Irini Sereti

National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD, US

814 CD8 T Cells in Lesions of PML-IRIS Express CCR5: Rationale for the Use of Maraviroc

Guillaume Martin-Blondel[2]; Jan Bauer[1]; Emmanuelle Uro-Coste[2]; Hervé Dumas[2]; Hans Lassmann[1]; David Brassat[2]; Pierre Delobel; Roland Liblau[3]; Bruno Marchou[2]

[1]University of Vienna, Vienna, Austria; [2]Toulouse University Hospital, Toulouse, France; [3]Inserm, Toulouse, France

815 Monocyte Immune Responses in Cryptococcal Immune Reconstitution Inflammatory Syndrome

David B. Meya[1]; Godfrey Zziwa[2]; Samuel Okurut[2]; Stephen Cose[3]; Paul Bohjanen[4]; Sharon Wahl[5]; David R. Boulware[4]; Yuka Manabe[6]; Edward N. Janoff[7]

[1]Makerere University College of Health Sciences, Kampala, Uganda; [2]Makerere University Walter Reed Project, Kampala, Uganda; [3]Medical Research Council, Kampala, Uganda; [4]University of Minnesota, Minneapolis, MN, US; [5]National Institute for Dental and Craniofacial Research, Bethesda, MD, US; [6]Johns Hopkins University School of Medicine, Baltimore, MD, US; [7]University of Colorado, Denver, CO, US

816LB Does HIV Infection Reduce the Probability of Transmission of Pulmonary Tuberculosis?

Judith R. Glynn[1]; José Afonso Guerra-Assunção[1]; Rein M. Houben[1]; Themba Mzembe[2]; Lifted Sichali[2]; Palwasha Y. Khan[1]; Ruth McNerney[1]; Julian Parkhill[3]; Taane G. Clark[1]; Amelia C. Crampin[1]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom; [2]Karonga Prevention Study, Chilumba, Malawi; [3]Wellcome Trust Sanger Institute, Hinxton, United Kingdom

Session P-R2 Poster Session — Poster Hall

2:30 pm – 4:00 pm

T-Cell Responses to Tuberculosis Infection

817 The Relationship Between T-Regulatory Cells and Latent Tuberculosis Infection in Household Contacts Exposed to Pulmonary Tuberculosis Infection in Kampala, Uganda

Rhoda Namakula[1]; Irene A. Odanga[2]; Josephine Kasolo[2]; Ekii A. Abuku[3]

[1]Makerere University–Johns Hopkins Research Collaboration, Kampala, Uganda; [2]Makerere University College of Health Sciences, Kampala, Uganda; [3]Medical Research Council (Uganda Virus Research Institute), Entebbe, Uganda

818 Antiretroviral Therapy Fails to Restore Mycobacterium Tuberculosis-specific Th1 and Th17 CD4 Responses

Lyle W. Murray[1]; Dominique Goedhals[2]; Iman Satti[1]; Rodney Phillips[1]; Helen McShane[1]; John Frater[1]
Phillips/Frater

[1]University of Oxford, Oxford, United Kingdom; [2]University of the Free State, Bloemfontein, South Africa

819 Treg/Th17 and T-Cell Effector Responses in Tuberculosis Patients Coinfected with HIV

Christine Lacabaratz[1]; Aurelie Wiedemann[1]; Celine Manier[1]; Laure Bourdery[1]; Mathieu Surenaud[1]; Jean-Daniel Lelièvre[2]; Giovanna Melica[3]; Yves Lévy[2]

[1]INSERM U955, Université Paris-Est Créteil, Vaccine Research Institute, Créteil, France; [2]INSERM U955, Université Paris-Est Créteil, Vaccine Research Institute, CHU H. Mondor-A.Chenevier, Créteil, France; [3]CHU H. Mondor-A.Chenevier, Créteil, France

820 HIV-Tuberculosis Coinfection Leads to Increased Turnover of Late-Senescent CD8$^+$ T Cells

Shankar Esaki Muthu[1]; Chong Yee Kien[1]; Alireza Saeidi[1]; Adeeba Kamarulzaman[1]; Vijayakumar Velu[2]; Marie Larsson[3]

[1]University of Malaya, Kuala Lumpur, Malaysia; [2]Emory University, Atlanta, GA, US; [3]Linkoping University, Linkoping, Sweden

821 CD8 T-Cell Terminal Differentiation and Its Regulation by DHEA in HIV-TB Coinfection

Guadalupe V. Suarez[1]; Matias T. Angerami[1]; Maria B. Vecchione[1]; Omar Sued[2]; Horacio Salomon[1]; Maria F. Quiroga[1]

[1]INBIRS (UBA-CONICET), Buenos Aires, Argentina; [2]Fundacion Huesped, Buenos Aires, Argentina

Session P-R3 Poster Session — Poster Hall

2:30 pm – 4:00 pm

TB Diagnostic Challenges

822 Unsuspected Prevalent TB among HIV-Infected Pregnant Women, South Africa

Jennifer D. Hoffmann[1]; **Silvia E. Cohn**[1]; Fildah Mashabela[2]; Ziyaad Waja[2]; Christopher J. Hoffmann[1]; Neil Martinson[2]; Richard E. Chaisson[1]
Tshepiso Study Team

[1]Johns Hopkins University School of Medicine, Baltimore, MD, US; [2]Perinatal HIV Research Unit (PHRU), Johannesburg, South Africa

823 Evaluation of WHO 4-Symptom Tool to Rule Out TB: Data From the XPHACTOR Study

Yasmeen Hanifa[1]; Katherine Fielding[1]; Violet Chihota[2]; Nontobeko Ndlovu[2]; Alan Karstaedt[3]; Lungiswa Adonis[4]; Linda Erasmus[5]; Mark Nicol[5]; Gavin Churchyard[2]; Alison Grant[1]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom; [2]Aurum Institute for Health Research, Johannesburg, South Africa; [3]Chris Hani Baragwanath Hospital, Johannesburg, South Africa; [4]Mamelodi Hospital, Pretoria, South Africa; [5]National Health Laboratory Service, Johannesburg, South Africa

824 Xpert MTB/RIF Versus AFB Smear to Determine Respiratory Isolation of US TB Suspects

Anne Luetkemeyer[1]; Cynthia Firnhaber[7]; Michelle Kendall[2]; Xingye Wu[2]; Debra Benator[3]; Gerald Mazurek[4]; Diane Havlir[1]; Beatriz Grinsztejn[5]; David Alland[6]
on behalf of the ACTG A5295/TBTC 34 Study Teams

[1]San Francisco General Hospital, University of California San Francisco, San Francisco, CA, US; [2]Harvard School of Public Health, Center for Biostatistics in AIDS Research, Boston, MA, US; [3]Washington DC Veterans Affairs Medical Center, Washington, DC, US; [4]US Centers for Disease Control and Prevention, Atlanta, GA, US; [5]Instituto de Pesquisa Clinica Evandro Chagas, Rio de Janiero, Brazil; [6]Rutgers New Jersey Medical School, Newark, NJ, US; [7]University of Witswatersrand, Johannesburg, South Africa; [8]ACTG A5295/TBTC 34 Study Teams, N/a, MA, US

825 Needle Autopsies Highlight Challenges in Defining HIV+ TB Deaths Using Verbal Autopsy

Aaron Karat[1]; Mpho Tlali[2]; Salome Charalambous[2]; Kerrigan McCarthy[2]; Violet Chihota[2]; Gavin Churchyard[2]; Katherine Fielding[1]; Kathleen Kahn[3]; Tanvier Omar[4]; Alison Grant[1]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom; [2]The Aurum Institute, Johannesburg, South Africa; [3]University of the Witwatersrand, Johannesburg, South Africa; [4]National Health Laboratory Service, Wits School of Public Health, Johannesburg, South Africa

826 Delta-Like 1 Protein, Vitamin D Binding Protein, and Fetuin Measurement in Cerebrospinal Fluid for Detection of *Mycobacterium tuberculosis* Meningitis

Nathan C. Bahr[1]; Ryan Halupnick; Grace Linder; Reuben Kiggundu[2]; Henry W. Nabeta[2]; Darlisha Williams[1]; Srinand Srevatsan[3]; Joshua Rhein[1]; David B. Meya[2]; David R. Boulware[1]

[1]University of Minnesota, Minneapolis, MN, US; [2]Makerere University College of Health Sciences, Kampala, Uganda; [3]University of Minnesota, Minneapolis, MN, US

827LB Adherence to Once-Weekly Self-Administered INH and Rifapentine for Latent TB: iAdhere

Robert Belknap[1]; Andrey Borisov[2]; David Holland[3]; Pei-Jean Feng[2]; Joan-Pau Millet[4]; Neil Martinson[5]; Alicia Wright[6]; Michael Chen[2]; Joan Cayla[4]; Jose M. Mida[7]
and the Tuberculosis Trials Consortium (TBTC)

[1]Denver Health and Hospital Authority, Denver, CO, US; [2]US Centers for Disease Control and Prevention, Altanta, GA, US; [3]Emory University, Atlanta, GA, US; [4]Tuberculosis Investigation Unit of Barcelona, Barcelona, Spain; [5]University of Witwatersrand, Johannesburg, South Africa; [6]Vanderbilt University, Nashville, TN, US; [7]Hospital Clinic–IDIBAPS, University of Barcelona, Barcelona, Spain

828LB Wirelessly Observed Therapy (WOT): A New Paradigm in TB Therapy Monitoring

Sara Browne[1]; Richard Haubrich[1]; Kathleen S. Moser[2]; Lorenzo DiCarlo[3]; Charles A. Peloquin[4]; Constance A. Benson[1]

[1]University of California San Diego, San Diego, CA, US; [2]San Diego County Health and Human Services Agency, San Diego, CA, US; [3]Proteus Digital Health Inc, Redwood City, CA, US; [4]University of Florida College of Pharmacy, Gainesville, FL, US

Session P-R4 Poster Session — Poster Hall

2:30 pm – 4:00 pm

TB Adverse Events, Recurrence, and Mortality

829 Severe Adverse Events in Outpatient Drug-Resistant TB Treatment in South Africa

Rebecca H. Berhanu[1]; Kathryn Schnippel[2]; Andrew Black[3]; Erika Mohr[4]; Busi Mncube[1]; Ian Sanne[1]

[1]Health Economics and Epidemiology Research Organisation, Johannesburg, South Africa; [2]Right to Care, Johannesburg, South Africa; [3]Reproductive Health Institute, University of Witswatersrand, Johannesburg, South Africa; [4]Médecins Sans Frontières, Cape Town, South Africa

830 Decreased TB Recurrence After Introduction of ART in Durban, South Africa

Yuri F. van der Heijden[1]; Farina Karim[2]; Gary Parker[2]; Tilagavathy Chinappa[3]; Grace Mufamadi[3]; Linda Zako[3]; Bryan E. Shepherd[1]; Timothy Sterling[1]; Alexander Pym[2]

[1]Vanderbilt University, Nashville, TN, US; [2]KwaZulu Natal Research Institute for TB and HIV (K-RITH), Durban, South Africa; [3]Ethekwini Municipality, Durban, South Africa

831 Incidence of Active Tuberculosis in HIV-Infected Adults and Mortality in Thailand

Nicolas Salvadori[1]; Suwalai Chalermpantmetagul[1]; Julie Figoni[1]; Suchart Thongpaen[2]; Ampaipith Nilmanat[3]; Patinun Chirawatthanaphan[4]; Pramual Thaingamsilp[5]; Tim R. Cressey[1]; Nicole Ngo-Giang-Huong[1]; Gonzague Jourdain[1]

[1]Institut de Recherche Pour le Développement UMI 174-PHPT, Chiang Mai, Thailand; [2]Mahasarakham Hospital, Mahasarakham, Thailand; [3]Hat Yai Hospital, Hat Yai, Thailand; [4]Phaholpolpayuhasaena Hospital, Kanchanaburi, Thailand; [5]Kalasin Hospital, Kalasin, Thailand

832 Antiretroviral Scale-up and Tuberculosis Mortality in High-Burden Countries

Eline Korenromp[2]; **Eran Bendavid**[1]; Isabel Yan[1]

[1]Stanford University, Stanford, CA, US; [2]Futures Institute, Glastonbury, CT, US

833 Culture-Negative TB Is Associated With Increased Mortality in HIV-Infected Persons

Timothy Sterling[1]; Cathy Jenkins[1]; Karu Jayathilake[1]; Eduardo Gotuzzo[2]; Valdilea Veloso[3]; Claudia P. Cortes[4]; Denis Padgett[5]; Brenda Crabtree-Ramirez[6]; Bryan E. Shepherd[1]; Catherine McGowan[1]
CCASAnet

[1]Vanderbilt University, Nashville, TN, US; [2]Universidad Peruana Cayetano Heredia, Lima, Peru; [3]Instituto Pequisa Evandro Chagas, Rio de Janeiro, Brazil; [4]University of Chile, Santiago, Chile; [5]Instituto Hondureno de Seguruidad Social, Tegucigalpa, Honduras; [6]Instituto Nacional de Ciencias Medicas y Nutricion, Mexico City, Mexico

THURSDAY, FEBRUARY 26, 2015

Session P-R5 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Cryptococcal Meningitis: Host Response, Treatment, and Outcomes

834 Local and Systemic Humoral Responses to Cryptococcal Meningitis in Patients With AIDS

Erin E. Finn[1]; Jordan Janoff[1]; Jeremy Rahkola[1]; David B. Meya[2]; Samuel Okurut[2]; Andrew D. Kambugu[2]; Paul Bohjanen[3]; Kirsten Nielsen[3]; David R. Boulware[3]; Edward N. Janoff[1]

[1]Mucosal and Vaccine Research Colorado, Aurora, CO, US; [2]Makerere University College of Health Sciences, Kampala, Uganda; [3]University of Minnesota, Minneapolis, MN, US

835 Antiretroviral Therapy Alters the CSF Immune Response in Cryptococcal Meningitis

James E. Scriven[1]; Britta Urban[1]; Lisa Graham[2]; Charlotte Schutz[2]; Robert J. Wilkinson[3]; David R. Boulware[4]; David Lalloo[1]; Graeme Meintjes[2]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom; [2]University of Cape Town, Cape Town, South Africa; [3]Imperial College London, London, United Kingdom; [4]University of Minnesota, Minneapolis, MN, US

836 Detrimental Outcomes of Unmasking Cryptococcal Meningitis With Recent ART Initiation

Joshua Rhein[1]; Katherine H. Hullsiek[1]; Nathan C. Bahr[1]; Reuben Kiggundu[3]; Darlisha Williams[3]; Henry W. Nabeta[3]; Abdu Musubire[3]; David B. Meya[3]; David R. Boulware[1]

[1]University of Minnesota, Minneapolis, MN, US; [2]University of Minnesota, Minneapolis, MN, US; [3]Makerere University College of Health Sciences, Kampala, Uganda

837 Impact of ART on Mortality in Cryptococcal Meningitis Patients: High-Income Settings

Suzanne M. Ingle[1]; Jose M. Miro[2]; Hansjakob Furrer[4]; Amy Justice[5]; Michael S. Saag[6]; Christian Manzardo[2]; Anna Esteve[7]; Lauren E. Cain[3]; Jonathan A. Sterne[1]; Margaret T. May[1]

[1]University of Bristol, Bristol, United Kingdom; [2]Hospital Clínic–L'Institut D'Investigacions Biomèdiques August Pi i Sunyer, University of Barcelona, Barcelona, Spain; [3]Harvard School of Public Health, Boston, MA, US; [4]Bern University Hospital and University of Bern, Bern, Switzerland; [5]Yale University School of Medicine, VA Connecticut Healthcare System, New Haven, CT, US; [6]University of Alabama at Birmingham, Birmingham, AL, US; [7]Centre d'Estudis Epidemiològics Sobre ITS/VIH/SIDA de Catalunya, Barcelona, Spain

838 Adjunctive Sertraline for the Treatment of HIV-Associated Cryptococcal Meningitis

Joshua Rhein[1]; Katherine H. Hullsiek[1]; Bozena Morawski[1]; Kyle Smith[1]; Ali Al-Hadab[1]; Abdu Musubire[2]; Darlisha Williams[2]; Kristen Nielsen[1]; David B. Meya[2]; David R. Boulware[1]

[1]University of Minnesota, Minneapolis, MN, US; [2]Makerere University College of Health Sciences, Kampala, Uganda

TUESDAY, FEBRUARY 24, 2015

Session P-R6 Poster Session — **Poster Hall**

2:30 pm – 4:00 pm

Syphilis and HIV Coinfection

839 Infection With HIV Among Individuals With Primary and Secondary Syphilis: USA, 2013

John R. Su; Akbar A. Zaidi; Elizabeth A. Torrone; Hillard S. Weinstock

US Centers for Disease Control and Prevention, Atlanta, GA, US

840 Risk Factors for Asymptomatic and Symptomatic Neurosyphilis Differ in HIV-Infected Patients With Syphilis

Christina Marra; Trudy Jones; Shelia Dunaway; Emily Ho; Abigail Crooks; Lauren Tantalo; Sharon Sahi

University of Washington, Seattle, WA, US

841 High Incidence of Syphilis Among Thai MSM Who Started ART Therapy During Acute HIV Infection

Donn J. Colby[1]; Suteeraporn Pinyakorn[1]; Frits van Griensven[1]; Eugene Kroon[1]; Naphassanant Laopraynak[1]; Robert O'Connell[2]; Nelson L. Michael[2]; Praphan Phanuphak[1]; Jintanat Ananworanich[2]; Nittaya Phanuphak[1]

[1]Thai Red Cross AIDS Research Center, Bangkok, Thailand; [2]US Military HIV Research Program, Bethesda, MD, US

842 Serological Response to Treatment of Syphilis in HIV-Positive and HIV-Negative Adults

Rulin C. Hechter[1]; Robyn Neblett Fanfair[2]; W-L Joanie Chung[1]; Lauri E. Markowitz[2]; Sean S. Anand[1]

[1]Kaiser Permanente Southern California, Pasadena, CA, US; [2]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US

Session P-R7 Poster Session — **Poster Hall**

2:30 pm – 4:00 pm

Opportunistic Infections: Odds and End Organs

843 The Exposure and Geospatial Risk Factors for AIDS-Associated Penicilliosis in Vietnam

Thuy Le[1]; Brian Jonat[2]; Ngo T. Cuc[3]; Nguyen T. Thanh[1]; Dang T. Bich[4]; Cecilia Shikuma[5]; Jeremy Day[1]; Heiman Wertheim[1]; Jeremy Farrar[1]; Marcel Wolbers[1]

[1]Oxford University Clinical Research Unit, Ho Chi Minh City, Viet Nam; [2]New York-Presbyterian University Hospital of Columbia and Cornell, New York City, NY, US; [3]Hospital for Tropical Diseases, Ho Chi Minh City, Viet Nam; [4]National Hospital for Tropical Diseases, Hanoi, Viet Nam; [5]Hawaii Center for AIDS, University of Hawaii, Ho Chi Minh, Viet Nam

844 A5265 Clinical Trial: Gentian Violet for Oral Candidiasis is as Effective as Nystatin

Pranab K. Mukherjee[1]; Lauren Patton[2]; James Hakim[4]; Huichao Chen[3]; Mai T. Pho[5]; Kenneth A. Freedberg[6]; Caroline Shiboski[7]; Mahmoud A. Ghannoum[1]; Robert A. Salata[1]
Oral HIV/AIDS Research Alliance (OHARA)/ACTG

[1]Case Western Reserve University, Cleveland, OH, US; [2]University of North Carolina, Chapel Hill, NC, US; [3]Harvard School of Public Health, Boston, MA, US; [4]University of Zimbabwe - Parirenyatwa, Harare, Zimbabwe; [5]University of Chicago, Chiago, IL, US; [6]Harvard Medical School, Boston, MA, US; [7]University of California San Francisco (UCSF), San Francisco, CA, US

845 Effective Treatment of Lymphogranuloma Venereum (LGV) With 1g Azithromycin Administered Weekly for 3 Weeks in an HIV-Infected Population

José L. Blanco; Irene Fuertes; Jordi Bosch; Ana Gonzalez; Andrea Vergara; Rob Camp; Esteban Martinez; Teresa Estrach; Josep M. Gatell; Merçe Alsina

Hospital Clinic, Barcelona, Barcelona, Spain

846 Risk Factors for Staphylococcus Aureus Carriage in HIV-Infected Adults in Southern Botswana

Michael J. Reid[1]; **Rebceca Fischer**[3]; Naledi Mannathoko[2]; Eric Brown[3]; Andrew Steenhoff[4]

[1]University of California San Francisco, San Francisco, CA, US; [2]University of Botswana, School of Medicine, Gaborone, Botswana; [3]University of Texas, Texas, Afghanistan; [4]University of Pennsylvania, Gaborone, Botswana

847 Specific Behaviors Predict *Staphylococcus aureus* Colonization and Skin and Soft Tissue Infections Among HIV-Infected Persons

Nancy Crum-Cianflone; Xun Wang; Amy Weintrob; Tahaniyat Lalani; Mary Bavaro; Katrin Mende; Michael Ellis; Brian K. Agan

Infectious Disease Clinical Research Program, San Diego, CA, US

848 Cytokine Profile in Aqueous Humor of HIV Patients With Ocular Opportunistic Infections

Matilde Ruiz-Cruz; Santiago Avila-Rios; Christopher Ormsby; Claudia Alvarado-de la Barrera; Yuria Ablanedo-Terrazas; Gustavo Reyes-Terán

National Institute of Respiratory Diseases, Mexico City, Mexico

849 Effects of *H. pylori* Co-infection on Immune Parameters in HIV-1 Patients in Ghana

Edmund Osei-Kuffour[1]; Torsten Feldt[1]; Kirsten A. Eberhardt[2]; Fred S. Sarfo[4]; Marieke Soltau[2]; Jan F. Drexler[3]; Gerd D. Burchard[2]; Carsten Münk[1]; Dieter Häussinger[1]
HHECO Study Group

[1]University Clinic Düsseldorf, Heinrich-Heine-University, Düsseldorf, Germany; [2]Bernhard-Nocht-Institute for Tropical Medicine, Hamburg, Hamburg, Germany; [3]University of Bonn, Bonn, Germany; [4]Kwame Nkrumah University of Science and Technology, Komfo Anokye Teaching Hospital, Kumasi, Ghana

THURSDAY, FEBRUARY 26, 2015

Session P-S1 Poster Session — **Poster Hall**

2:30 pm – 4:00 pm

Access and Engagement

850 Trends in Healthcare Access and HIV Risk Behaviors—African American Women, 2006-2013

Wade Ivy; Gabriela Paz-Bailey

US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US

851 Engagement in the HIV Care Continuum Among Female Sex Workers in Lilongwe, Malawi

Kathryn E. Lancaster[1]; Thandie Lungu[3]; Mina C. Hosseinipour[3]; Katy Chadwick[2]; Zoe Dibb[2]; Vivian F. Go[1]; Brian W. Pence[1]; Kimberly A. Powers[1]; Irving F. Hoffman[1]; William C. Miller[1]

[1]University of North Carolina, Chapel Hill, NC, US; [2]Theatre for a Change, Lilongwe, Malawi; [3]University of North Carolina Project–Malawi, Lilongwe, Malawi

852 New HIV Cases and ARV Retention in Pretoria: A Gender Project for High-Risk Women

Wendee M. Wechsberg[1]; William A. Zule[1]; Irene A. Doherty[1]; Tracy L. Kline[1]; Jacqueline Ndirangu[1]; Charles M. van der Horst[2]

[1]RTI International, Research Triangle Park, NC, US; [2]University of North Carolina, Chapel Hill, NC, US

853 Intimate Partner Violence and Antiretroviral Adherence in HIV-Positive Women in Kenya

Kate S. Wilson[1]; Krista Yuhas[1]; Ruth Deya[1]; Barbra Richardson[1]; Linnet Masese[1]; Jane Simoni[1]; Walter Jaoko[2]; R Scott McClelland[1]

[1]University of Washington, Seattle, WA, US; [2]University of Nairobi, Nairobi, Kenya

854 Re-engagement in Care Leads to Sustained Engagement and Viral Suppression

Brittani D. Saafir-Callaway[1]; Amanda D. Castel[2]; Lena Lago[1]; Christie Olejemeh[1]; Garret Lum[1]; Lawrence Frison[1]; Michael Kharfen[1]

[1]District of Columbia Department of Health, Washington, DC, US; [2]The Milken Institute School of Public Health at George Washington University, Washington, DC, US

TUESDAY, FEBRUARY 24, 2015

Session P-S2 Poster Session — **Poster Hall**

2:30 pm – 4:00 pm

Cervical Sampling, Shedding, and Outcomes

855 Symptoms and Genital HSV-2 and HIV-1 in Coinfected Women, Chiang Rai, Thailand

Eileen F. Dunne[1]; Brooke E. Hoots[1]; Janet McNicholl[1]; Sara Whitehead[2]; Thomas A. Peterman[2]; Lauri E. Markowitz[2]; Wanna Leelawiwat[3]; Tammy Evans-Strickfaden[1]; Cheng Chen[1]

[1]US Centers for Disease Control and Prevention, Bangkok, Thailand; [2]US Centers for Disease Control and Prevention, Atlanta, GA, US; [3]Thailand Ministry of Public Health–US CDC Collaboration, Nonthaburi, Thailand

856 High-Risk HPV Clustering and Cervical Outcomes in HIV-Infected Women in Rio de Janeiro, Brazil

Jessica L. Castilho[1]; José Eduardo Levi[2]; Paula M. Luz[2]; Mary Catherine Cambou[3]; Tazio Vanni[4]; Angela de Andrade[2]; Monica Derrico[2]; Valdilea Veloso[2]; Beatriz Grinsztejn[2]; Ruth Friedman[2]

[1]Vanderbilt University School of Medicine, Nashville, TN, US; [2]Fundação Oswaldo Cruz, Rio de Janeiro, Brazil; [3]University of California Los Angeles, Los Angeles, CA, US; [4]United Nations, Lyons, France

857 Comparison of Three Female Genital Tract Sampling Techniques for HIV RNA Recovery

Catherine S. Todd[1]; Shameem Jaumdally[2]; Heidi E. Jones[3]; Hoyam Gamieldien[2]; Nontokozo Langwenya[4]; Landon Myer[4]; Donald R. Hoover[5]; Jo-Ann Passmore[1]

[1]FHI360, Bangkok, Thailand; [2]University of Cape Town, Cape Town, South Africa; [3]Hunter College, CUNY School of Public Health, New York, NY, US; [4]University of Cape Town, Cape Town, South Africa; [5]Rutgers New Jersey Medical School, Piscataway, NJ, US

THURSDAY, FEBRUARY 26, 2015

Session P-S3 Poster Session — **Poster Hall**

2:30 pm – 4:00 pm

Hormonal Contraception

858 CCR5 Expression in HIV-Uninfected Women Receiving Hormonal Contraception

Athe Tsibris[1]; Gaia Sciaranghella[2]; Cuiwei Wang[3]; Kerry Murphy[4]; Zaher Mehri[5]; Ruth M. Greenblatt[6]; Mardge Cohen[7]; Elizabeth Golub[8]; Heather Watts[9]; Mary A. Young[3]

[1]Brigham and Women's Hospital, Harvard Medical School, Cambridge, MA, US; [2]Ragon Institute of MIT, MGH and Harvard, Boston, MA, US; [3]Georgetown University Medical Center, Washington, DC, US; [4]Albert Einstein College of Medicine, Bronx, NY, US; [5]University of Vermont College of Medicine, Burlington, VT, US; [6]University of California San Francisco, San Francisco, CA, US; [7]Stroger Hospital and Rush University and CORE Center, Chicago, IL, US; [8]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [9]The Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD, US

859 Estrogen Replacement in Healthy Postmenopausal Women Reduces %CCR5+ CD4+ T Cells

Amie Meditz[1]; Samantha MaWhinney[2]; Kerrie Moreau[2]; Kelsey Melander[2]; Joy Folkvord[2]; Wendy Kohrt[2]; Margaret Wierman[2]; Elizabeth Connick[2]

[1]Boulder Community Health, Boulder, CO, US; [2]University of Colorado Anschutz Medical Campus, Aurora, CO, US

860 Progesterone Increases Are Associated With HIV Susceptibility Factors in Women

Alison Y. Swaims[1]; Tammy Evans-Strickfaden[1]; L Davis Lupo[1]; Alfredo Aguirre[2]; Anandi Sheth[2]; Igho Ofotokun[2]; Clyde E. Hart[1]; **Richard E. Haaland**[1]

[1]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US; [2]Emory University School of Medicine, Atlanta, GA, US

861 Changes in Vaginal Microbiota and Cytokines in HIV-1-Seronegative Women Initiating DMPA

Alison C. Roxby[1]; David N. Fredricks[2]; Katherine Odem-Davis[1]; Kristjana H. Ásbjörnsdóttir[1]; Linnet Masese[1]; Tina L. Fiedler[2]; Walter Jaoko[3]; James N. Kiarie[3]; Julie M. Overbaugh[2]; R Scott McClelland[1]

[1]University of Washington, Seattle, WA, US; [2]Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US; [3]University of Nairobi, Nairobi, Kenya

862 A Thinned Vaginal Stratum Corneum Is a Susceptibility Factor for SHIV Acquisition

Ellen Kersh; Jana Ritter; Katherine Butler; Sharon Dietz Ostergaard; Debra Hanson; Sherif Zaki; Janet McNicholl

US Centers for Disease Control and Prevention, Atlanta, GA, US

TUESDAY, FEBRUARY 24, 2015

Session P-T1 Poster Session — **Poster Hall**

2:30 pm – 4:00 pm

How Fast? How Often? Achieving Viral Suppression in Pregnant and Postpartum Women

863 Specific Effects of ZDV, 3TC and LPV/r on HIV-1 RNA Viral Load During Pregnancy

Patumrat Sripan[1]; Sophie Le Coeur[5]; Lily Ingsrisawang[2]; Tim R. Cressey[3]; Jean-Marc Tréluyer[6]; Naïm Bouazza[4]; Frantz Foissac[4]; Gonzague Jourdain[3]; Marc G. Lallemant[3]; Saïk Urien[7]

[1]ED420, University of Paris Sud 11, Paris Descartes, Paris, France/PHPT-IRD UMI 174, Chiang Mai, Thailand/Department of Statistics, Faculty of Science, Kasetsart University, Bangkok, Thailand; [2]Department of Statistics, Faculty of Science, Kasetsart University, Bangkok, Thailand; [3]PHPT-IRD UMI 174, Faculty of Associated Medical Sciences, Chiang Mai University/ Harvard School of Public Health, Chiang Mai, Thailand; [4]EA 08 Université Paris Descartes, Sorbonne Paris Cité, Unité de Recherche Clinique, AP-HP, Hôpital Tarnier, Paris, France; [5]Institut d'Etudes Démographiques, Institut de Recherche Pour le Développement (UMR 196 CEPED), Paris, France/Harvard School of Public Health, Boston, MA, USA/Faculty of Associated Medical Science, Chiang Mai University, Chiang Mai, Thailand; [6]EA 08 Université Paris Descartes, Sorbonne Paris Cité, Unité de Recherche Clinique, AP-HP, Hôpital Tarnier, Service de Pharmacologie Clinique, AP-HP, Groupe Hospitalier Paris Centre, CIC-0901 Inserm, Cochin-Necker, Paris, France; [7]EA 08 Université Paris Descartes, Sorbonne Paris Cité, Unité de Recherche Clinique, AP-HP, Hôpital Tarnier, CIC-0901 Inserm, Cochin-Necker, Paris, France

864 Viral Suppression After Antiretroviral Therapy Initiation in Pregnancy in South Africa

Landon Myer[1]; Tamsin Phillips[1]; Nei-Yuan Hsiao[2]; Allison Zerbe[3]; Jo Ramjith[1]; Linda-Gail Bekker[1]; James A. McIntyre[4]; Elaine J. Abrams[3]

[1]University of Cape Town, Cape Town, South Africa; [2]National Health Laboratory Services/ University of Cape Town, Cape Town, South Africa; [3]ICAP at Columbia University, New York, NY, US; [4]Anova Health Institute, Johannesburg, South Africa

865 Maternal Viral Load in the Context of PMTCT B+ Within the Kabeho Study in Kigali

Emily A. Bobrow[1]; Placidie Mugwaneza[2]; Gilles F. Ndayisaba[3]; Dieudonne Ndatimana[3]; **Michelle Gill**[1]; Heather J. Hoffman[4]; Cyprien Baribwira[5]; Laura Guay[1]; Anita Asiimwe[6]
Kabeho Study Team

[1]Elizabeth Glaser Pediatric AIDS Foundation, Washington, DC, US; [2]Ministry of Health, Kigali, Rwanda; [3]Elizabeth Glaser Pediatric AIDS Foundation, Kigali, Rwanda; [4]George Washington University Milken Institute School of Public Health, Washington, DC, US; [5]University of Maryland, School of Medicine, Kigali, Rwanda; [6]Rwanda University Teaching Hospitals, Kigali, Rwanda

866 ART Response Among Pregnant and Postpartum Women With Acute Versus Chronic HIV-1

Alison L. Drake[1]; John Kinuthia[2]; Daniel Matemo[2]; Barbra Richardson[1]; Michael Chung[1]; James N. Kiarie[2]; Sandy Emery[3]; Julie M. Overbaugh[3]; Grace John-Stewart[1]

[1]University of Washington, Seattle, WA, US; [2]University of Nairobi, Nairobi, Kenya; [3]Fred Hutchinson Cancer Research Center, Seattle, WA, US

Session P-T2 Poster Session **Poster Hall**

2:30 pm – 4:00 pm

Rates and Risks of MTCT and HIV-Free Survival

867 No Perinatal Transmission of HIV-1 in Women Efficiently Treated Since Conception

Laurent Mandelbrot[1]; Roland Tubiana[2]; Jérome Le Chenadec[3]; Catherine Dollfus[4]; Albert Faye[5]; Christine Rouzioux[6]; Anais Perilhou[3]; **Josiane Warszawski**[7]; Stéphane Blanche[6]
The ANRS-EPF (CO1/CO10/CO11) Study Group

[1]AP-HP, Hôpital Louis Mourier - INSERM U1018, CESP - Université Paris 7, Colombes, France; [2]AP-HP, Hôpital Pitié Salpêtrière - INSERM, U943, Paris, France; [3]INSERM CESP U1018, Le Kremlin-Bicetre, France; [4]AP-HP, Hôpital Trousseau, Paris, France; [5]AP-HP, Hôpital Robert Debre-University Paris 7, Paris, France; [6]AP-HP, Hôpital Necker-Enfants Malades, University Paris-Descartes, Paris, France; [7]University Paris-Sud - INSERM CESP U1018 - AP-HP Hopital Bicetre, Le Kremlin-Bicetre, France

868 Predictors of Perinatal HIV Transmission in the BAN Study

Sascha R. Ellington[1]; **Athena P. Kourtis**[1]; Ali Fokar[2]; Charles S. Chasela[4]; Dumbani Kayira[3]; Gerald Tegha[3]; Denise J. Jamieson[1]; Charles M. van der Horst[2]
The BAN Study Team

[1]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US; [2]University of North Carolina, Chapel Hill, NC, US; [3]University of North Carolina Project Lilongwe, Lilongwe, Malawi; [4]University of Witwatersrand, Johannesburg, South Africa

869 High Rate of HIV Superinfection After Delivery: Secondary Analysis of the PEPI Trial

Andrew D. Redd[1]; Sarah Wendel[1]; Andrew Longosz[1]; Jessica M. Fogel[2]; Newton Kumwenda[3]; Sufia Dadabhai[3]; Susan H. Eshleman[2]; Stephen Porcella[4]; Thomas C. Quinn[1]; Taha Taha[3]

[1]National Institute of Allergy and Infectious Diseases, Baltimore, MD, US; [2]Johns Hopkins University School of Medicine, Baltimore, MD, US; [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [4]National Institute of Allergy and Infectious Diseases (NIAID), Hamilton, MT, US

870 Decline in Early Mother-to-Child HIV Transmission (MTCT) Risk Over Time in Botswana

Kathleen M. Powis[1]; Gbolahan Ajibola[2]; Jean Leidner[3]; Kara Bennett[4]; Florence Chilisa[2]; Keabetwe Bedi[2]; Chipo Petlo[7]; Michael D. Hughes[8]; Roger Shapiro[5]; Shahin Lockman[6]

[1]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [2]Botswana Harvard AIDS Institute, Gaborone, Botswana; [3]Goodtables Data Consulting, Norman, OK, US; [4]Bennett Statistical Consulting, Inc, Ballston Lake, NY, US; [5]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, US; [6]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, US; [7]Botswana Ministry of Health, Gaborone, Botswana; [8]Harvard School of Public Health, Center for Biostatistics in AIDS Research, Boston, MA, US

871 Impact of Maternal Antiretroviral Regimen on Six-Month HIV-Free Survival in Botswana

Rebecca Zash[1]; Sajini Souda[2]; Chazha Hick[3]; Kelebogile Binda[3]; Sikhulile Moyo[3]; Erik van Widenfeldt[3]; Jean Leidner[4]; Joseph Makhema[3]; Mompati Mmalane[3]; Roger Shapiro[1]

[1]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, US; [2]University of Botswana, Gaborone, Botswana; [3]Botswana Harvard AIDS Institute, Gaborone, Botswana; [4]Harvard School of Public Health, Boston, MA, US

872 Infant Outcomes Among a Cohort of HIV-Infected Pregnant Women With and Without TB in South Africa: The Tshepiso Study

Jennifer D. Hoffmann[1]; Silvia E. Cohn[1]; **Nicole M. Salazar-Austin**[1]; Fildah Mashabela[2]; Ziyaad Waja[2]; Christopher J. Hoffmann[1]; Sanjay Lala[3]; Richard E. Chaisson[1]; Neil A. Martinson[2]

[1]Johns Hopkins University School of Medicine, Baltimore, MD, US; [2]Perinatal HIV Research Unit (PHRU), Johannesburg, South Africa; [3]Chris Hani Baragwanath Hospital, Johannesburg, South Africa

Session P-T3 Poster Session **Poster Hall**

2:30 pm – 4:00 pm

Option B+: Retention and Transmission

873 Early HIV Infection Rate Trends in Exposed Infants Pre- and Post-Option B+ in Mozambique

Thresia Sebastian; Serena Brusamento; Laurence Ahoua; Dario Aly; Stephen M. Arpadi; Chloe A. Teasdale; Fatima Tsiouris; Elaine J. Abrams

ICAP at Columbia University, New York, NY, US

874 Option B+ Scale Up and Comprehensive PMTCT Service Delivery in Central Malawi

Michael E. Herce[1]; Tiwonge Mtande[2]; Frank Chimbwandira[3]; Innocent Mofolo[2]; Christine Chingondole[2]; Nora Rosenberg[4]; Kathryn Lancaster[4]; Mina C. Hosseinipour[1]; Charles M. van der Horst[1]
Safeguard the Family—Malawi Ministry of Health Partnership

[1]University of North Carolina, Lusaka, Zambia; [2]UNC Project-Malawi, Lilongwe, Malawi; [3]Malawi Ministry of Health, Lilongwe, Malawi; [4]University of North Carolina, Chapel Hill, NC, US

875 Retention Amongst HIV-Infected Pregnant Women Initiating Lifelong Antiretroviral Treatment (Option B+) in Haiti

Jean W. Domercant[2]; Nancy Puttkammer[3]; **Lydia Lu**[1]; Kesner Francois[4]; Olbeg Desinor[5]; Reginald Jean_Louis[2]; Michelle Adler[1]; Barbara Marston[1]; Reynold Grand'Pierre[4]

[1]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US; [2]US Centers for Disease Control and Prevention (CDC), Port au Prince, Haiti; [3]International Training and Education Center for Health, Seattle, WA, US; [4]Ministry of Health of the Government of Haiti, Port au Prince, Haiti; [5]US Agency for International Development, Port au Prince, Haiti

THURSDAY, FEBRUARY 26, 2015

Session P-T4 Poster Session **Poster Hall**

2:30 pm – 4:00 pm

Health Outcomes of HIV- and ARV-Exposed Infants, Children, and Youth

876 Malnutrition Among HIV-Exposed Uninfected Children in Botswana

Kathleen M. Powis[1]; Quanhong Lei[2]; Yvonne Chinyanga[3]; Esther Tumbare[4]; Nealia Khan[5]; Jacinta Sibiya[3]; Erik van Widenfelt[6]; Joseph Makhema[6]; Roger Shapiro[7]

[1]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [2]Harvard School of Public Health, Center for Biostatistics in AIDS Research, Boston, MA, US; [3]Botswana Ministry of Health, Gaborone, Botswana; [4]Elizabeth Glaser Pediatric AIDS Foundation, Harare, Zimbabwe; [5]Harvard School of Public Health, Boston, MA, US; [6]Botswana Harvard AIDS Institute, Gaborone, Botswana; [7]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, US

877 Hospitalizations Among Uninfected Children Exposed or Unexposed to HIV – A Nationwide Cohort Study

Ellen M. Larsen[1]; Marie Helleberg[2]; Sannie Nordly[3]; Nina Weis[3]; Vibeke Rosenfeldt[3]; Merete Storgaard[4]; Gitte Pedersen[5]; Isik S. Johansen[6]; Suzanne Lunding[1]; Terese L. Katzenstein[2]

[1]Nordsjællands Hospital, Hillerød, Denmark; [2]Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark; [3]Copenhagen University Hospital, Hvidovre, Hvidovre, Denmark; [4]Aarhus University Hospital, Skejby, Aarhus, Denmark; [5]Aalborg University Hospital, Aalborg, Denmark; [6]Odense University Hospital, Odense, Denmark

878 Reassuring Birth Outcomes Data With Atripla Used for PMTCT in Botswana

Rebecca Zash[1]; Jennifer Y. Chen[2]; Sajini Souda[3]; Scott Dryden-Peterson[4]; Shahin Lockman[4]; Mompati Mmalane[3]; Joseph Makhema[3]; Max Essex[5]; Roger Shapiro[1]

[1]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, US; [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [3]Botswana Harvard AIDS Institute, Gaborone, Botswana; [4]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, US; [5]Harvard School of Public Health, Boston, MA, US

879 Growth and Bone Markers in Malawian Infants Pre- and Postnatally Exposed to Tenofovir

Giuseppe Liotta[2]; Marco Floridia[1]; **Mauro Andreotti**[1]; Haswell Jere[3]; Clementina Galluzzo[1]; Sandro Mancinelli[2]; Maria Cristina Marazzi[4]; Stefano Vella[1]; Marina Giuliano[1]; Leonardo Palombi[2]

[1]Istituto Superiore di Sanità, Rome, Italy; [2]University of Tor Vergata, Rome, Italy; [3]Community of S.Egidio, Blantyre, Malawi; [4]Lumsa University, Rome, Italy

880 Lower Insulin, Acylcarnitines, and Branch-Chain Amino Acids in HIV-Exposed Infants

Jennifer Jao[1]; Brian Kirmse[2]; Chunli Yu[3]; Fanny Epie[4]; Emmanuel Nshom[4]; Rhoda Sperling[5]; Elaine J. Abrams[6]; Derek LeRoith[7]; Mitchell Geffner[8]; Irwin Kurland[9]

[1]Icahn School of Medicine at Mount Sinai, New York, NY, US; [2]Children's National Health System, Washington, DC, US; [3]Icahn School of Medicine at Mount Sinai, New York, NY, US; [4]Cameroon Baptist Convention Health Services, Bamenda, Cameroon; [5]Icahn School of Medicine at Mount Sinai, New York, NY, US; [6]ICAP at Columbia University, New York, NY, US; [7]Icahn School of Medicine at Mount Sinai, New York, NY, US; [8]Keck School of Medicine at University of Southern California, Los Angeles, CA, US; [9]Albert Einstein College of Medicine, New York, NY, US

881 No Effect of Maternal HIV and In-Utero cART on Infant Leukocyte Telomere Length

Abhinav Ajaykumar[1]; Hugo Soudeyns[2]; Fatima Kakkar[2]; Jason Brophy[3]; Ari Bitnun[4]; Ariane Alimenti[1]; Deborah Money[1]; Arianne Albert[5]; Hélène C. Côté[1]
On behalf of the CIHR Team in Cellular Aging and HIV Comorbidities in Women and Children (CARMA)

[1]University of British Columbia, Vancouver, Canada; [2]Université de Montréal, Montreal, Canada; [3]University of Ottawa, Ottawa, Canada; [4]University of Toronto, Toronto, Canada; [5]Women's Health Research Institute, Vancouver, Canada

882 Long-Term Effects of In Utero ARV Exposure on Cardiac Function in HIV-Exposed Uninfected Youth

Vitor C. Guerra[1]; Erin Leister[2]; Paige L. Williams[2]; Steven E. Lipshultz[3]; Russell Van Dyke[1]; Rohan Hazra[4]; Steven D. Colan[5]

[1]Tulane University, New Orleans, LA, US; [2]Harvard School of Public Health, Center for Biostatistics in AIDS Research, Boston, MA, US; [3]Wayne State University School of Medicine, Detroit, MI, US; [4]Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD, US; [5]Boston Children's Hospital, Harvard Medical School, Boston, MA, US

Session P-T5 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Coinfections Among HIV-Exposed Infants and Children

883 Burden of Malaria in a Birth Cohort of HIV-Exposed Ugandan Infants

Abel Kakuru[2]; Paul Natureeba[2]; Albert Plenty[1]; Edwin Charlebois[1]; Deborah Cohan[1]; Tamara Clark[1]; Diane Havlir[1]; Moses R. Kamya[3]; Grant Dorsey[1]; **Theodore Ruel**[1]

[1]University of California San Francisco, San Francisco, CA, US; [2]Makerere University-University of California, San Francisco Research Collaboration, Kampala, Uganda; [3]Makerere University College of Health Sciences, Kampala, Uganda

884 CMV Transmission From HIV-infected Women Randomized to Formula Versus Breastfeeding

Barbra Richardson[1]; Grace John-Stewart[1]; Vincent Emery[2]; Claire Atkinson[4]; Ruth Nduati[3]; Kristjana H. Ásbjörnsdóttir[1]; Julie M. Overbaugh[5]; Michael Boeckh[5]; **Jennifer A. Slyker**[1]

[1]University of Washington, Seattle, WA, US; [2]University of Surrey, Guildford, United Kingdom; [3]University of Nairobi, Nairobi, Kenya; [4]University College London, London, United Kingdom; [5]Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US

885 Is the Prevalence of *M. tuberculosis* Infection Higher in HIV-Exposed Children?

Palwasha Y. Khan[1]; Katherine L. Fielding[1]; Dominic Mulawa[2]; Regina Chiumya[2]; Themba Mzembe[2]; Olivier Koole[1]; Judith R. Glynn[1]; Amelia C. Crampin[1]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom; [2]Karonga Prevention Study, Karonga, Malawi

TUESDAY, FEBRUARY 24, 2015

Session P-T6 Poster Session — Poster Hall

2:30 pm – 4:00 pm

ART Adherence, Adverse Effects, and Retention Among Pregnant Women and Infants

886 ARV Adherence Associated with Reduced Breastmilk HIV Viral Load and HIV Transmission

Nicole L. Davis[4]; **William C. Miller**[4]; Michael G. Hudgens[4]; Charles S. Chasela[1]; Dorothy Sichali[2]; Julie A. Nelson[4]; Joseph Rigdon[4]; Sascha R. Ellington[3]; Athena P. Kourtis[3]; Charles M. van der Horst[4]
BAN study team

[1]University of Witswatersand, Johannesburg, South Africa; [2]UNC Project-Malawi, Lilongwe, Malawi; [3]US Centers for Disease Control and Prevention (CDC), Atlantaq, GA, US; [4]University of North Carolina, Chapel Hill, NC, US

887 Peripartum Hair Levels of Antiretrovirals Predict Viral Suppression in Ugandan Women

Catherine A. Koss[1]; Peter Bacchetti[1]; Deborah Cohan[1]; Paul Natureeba[1]; Howard Horng[1]; Tamara Clark[1]; Edwin Charlebois[1]; Moses R. Kamya[2]; Diane Havlir[1]; Monica Gandhi[1]

[1]University of California San Francisco, San Francisco, CA, US; [2]Makerere University College of Health Sciences, Kampala, Uganda

888 Side Effects and Treatment Adherence After ART Initiation in Pregnancy in South Africa

Tamsin Phillips[1]; Allison V. Zerbe[2]; Agnes Ronan[1]; Claude A. Mellins[3]; Robert H. Remien[3]; James A. McIntyre[4]; Greg Petro[1]; Elaine J. Abrams[2]; Landon Myer[1]

[1]University of Cape Town, Cape Town, South Africa; [2]ICAP at Columbia University, New York, NY, US; [3]New York State Psychiatric Institute and Columbia University, New York, NY, US; [4]Anova Health Institute, Johannesburg, South Africa

889 Efficacy of Mobile Phone Use on Adherence to Nevirapine Prophylaxis and Retention in Care Among HIV-Exposed Infants

Lilian M. Kebaya; Dalton Wamalwa; Nyambura Kariuki; Bashir Admani; Ruth W. Nduati

University of Nairobi, Nairobi, Kenya

890 HIV Care Continuum for Postpartum Women in Philadelphia: Barriers and Facilitators

Joella W. Adams[1]; Kathleen Brady[1]; Yvonne Michael[3]; Baligh R. Yehia[4]; Florence Momplaisir[2]

[1]Philadelphia Department of Public Health, Philadelphia, PA, US; [2]Drexel University College of Medicine, Philadelphia, PA, US; [3]Drexel University School of Public Health, Philadelphia, PA, US; [4]University of Pennsylvania, Philadelphia, PA, US

Session P-T7 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Pharmacokinetics and Safety of ART During Pregnancy

891 Raltegravir Plasma Concentrations on HIV-1 Infected Pregnant Women

Emilie Belissa; Amine Benchikh; Charlotte Charpentier; Morgane Valentin; Agnes Bourgeois-Moine; Sylvie Lariven; Florence Damond; Yazdan Yazdanpanah; Sophie Matheron; **Gilles Peytavin**

APHP, Bichat-Claude Bernard Hospital, Paris, France

892 Etravirine Pharmacokinetics During Pregnancy and Postpartum

Brookie M. Best[1]; Angela Colbers[2]; Jiajia Wang[3]; Graham Taylor[4]; Alice Stek[5]; Marjo van Kasteren[6]; Mark Mirochnick[7]; David Burger[2]
On behalf of the IMPAACT P1026s Protocol Team and the PANNA Network

[1]University of California San Diego, San Diego, CA, US; [2]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [3]Center for Biostatistics in AIDS Research, Harvard School of Public Health, Boston, MA, US; [4]Imperial College Healthcare NHS Trust, London, United Kingdom; [5]University of Southern California School of Medicine, Los Angeles, CA, US; [6]St. Elisabeth Hospital, Tilburg, Netherlands; [7]Boston University School of Medicine, Boston, MA, US

893 Pharmacokinetics of Etravirine in HIV-1–Infected Pregnant Women

M Ramgopal[1]; O Osiyemi[2]; C Zorrilla[3]; HM Crauwels[4]; R Ryan[5]; K Brown[6]; V Hillewaert[7]; B Baugh[6]

[1]Midway Immunology and Research Center, Fort Pierce, FL, US; [2]Triple O Research Institute PA, West Palm Beach, FL, US; [3]University of Puerto Rico School of Medicine, San Juan, US; [4]Janssen Infectious Diseases, Beerse, Belgium; [5]Janssen Research & Development, Titusville, NJ, US; [6]Janssen Therapeutics, Titusville, NJ, US; [7]Janssen Research & Development, Beerse, Belgium

894 Pharmacokinetics of Rilpivirine in HIV-Infected Women During Pregnancy and Postpartum

Mark Mirochnick[1]; Brookie M. Best[2]; Alice Stek[3]; Regis Kreitchmann[8]; Jiajia Wang[4]; David Shapiro[4]; Elizabeth Smith[5]; Lynne Mofenson[6]; Tim R. Cressey[7]; Edmund Capparelli[2]

[1]Boston University School of Medicine, Hingham, MA, US; [2]University of California San Diego, San Diego, CA, US; [3]University of Southern California, Los Angeles, CA, US; [4]Harvard School of Public Health, Boston, MA, US; [5]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD, US; [6]Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD, US; [7]Harvard School of Public Health/Chiang Mai University, Chang Mai, Thailand; [8]Irmandade da Santa Casa de Misericordia de Porto Alegre, Porte Alegre, Brazil

894-A Pharmacokinetics of Rifampin in TB/HIV-Coinfected Women: Does Pregnancy Matter?

Paolo Denti[1], Helen McIlleron[1], Neil Martinson[2], Silvia Cohn[2], Jennifer Hoffmann[2], Richard Chaisson[2], Kelly Dooley[2], Fildah Mashabela[3], Regina Msandiwa[3]
On behalf of the TSHEPISO Study Team

[1]Division of Clinical Pharmacology, University of Cape Town, Cape Town, South Africa; [2]Johns Hopkins University School of Medicine, Baltimore, Maryland, United States; [3]Perinatal HIV Research Unit, University of the Witwatersrand, Soweto, South Africa

Session P-T8 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Planning and Preventing Pregnancy

895 Safer Conception Delayed by Lack of HIV Viral Suppression

Sheree R. Schwartz[1]; Rebecca Phofa[2]; Nompumelelo Yende[2]; Jean Bassett[2]; Nora West[2]; Ian Sanne[3]; Annelies Van Rie[1]

[1]University of North Carolina, Chapel Hill, NC, US; [2]Witkoppen Health and Welfare Centre, Johannesburg, South Africa; [3]University of the Witwatersrand, Johannesburg, South Africa

896 Preventing Unintended Pregnancy and HIV: The HIV Treatment Cascade and Contraceptive Choices

Julia Raifman[1]; Terusha Chetty[2]; Frank Tanser[2]; Tinofa Mutevedzi[2]; Philippa Matthews[2]; Kobus Herbst[2]; Deenan Pillay[2]; Till Barnighausen[1]

[1]Harvard School of Public Health, Washington, DC, US; [2]Africa Centre for Health and Population Studies, Mtubatuba, South Africa

THURSDAY, FEBRUARY 26, 2015

Session P-T9 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Mechanisms of MTCT and Maternal/Infant Health

897 HIV Target Cells and Altered Microbiome Associated With Mixed Feeding in South Africa

Lianna F. Wood[1]; Cosette LeCiel[2]; Heather Jaspan[3]; Donald Sodora[2]

[1]University of Washington, Seattle, WA, US; [2]Seattle BioMed, Seattle, WA, US; [3]Seattle Children's Hospital, Seattle, WA, US

898 Role of Type 1 IFNs in the Control of HIV-1 Infection at the Feto-Maternal Interface

Erica L. Johnson; Sahithi Boggavarapu; Elan S. Johnson; Asim A. Lal; Siddhartha Bhaumik; Murali-Krishna Kaja; Rana Chakraborty

Emory University School of Medicine, Atlanta, GA, US

899 Immune Activation During Pregnancy and Postpartum Period in Treated HIV+ Ugandans

Peter W. Hunt[1]; Helen Byakwaga[2]; Yap Boum[2]; Lynn T. Matthews[3]; Tricia H. Burdo[4]; Yong Huang[1]; Annet Kembabazi[2]; Angela Kaida[5]; David R. Bangsberg[3]; Jeffrey Martin[1]

[1]University of California San Francisco, San Francisco, CA, US; [2]Mbarara University of Science and Technology, Mbarara, Uganda; [3]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [4]Boston College, Boston, MA, US; [5]Simon Fraser University, Vancouver, Canada

900 T-Cell Activation and Exhaustion in HIV-Infected and HIV-Uninfected Pregnant Women

Christina Fiske; Vlada Melekhin; Fernanda Maruri; Cindy Hager; Louise Barnett; Timothy Sterling; Spyros Kalams

Vanderbilt University School of Medicine, Nashville, TN, US

901 HIV and Smoking Associated with Shorter Telomere Length in a Cohort of Pregnant Women

Sara Saberi[1]; Beheroze Sattha[1]; Evelyn Maan[2]; Julie Van Schalkwyk[3]; Deborah Money[1]; Hélène Côté[1]
On behalf of the CIHR Team in Cellular Aging and HIV Comorbidities in Women and Children (CARMA)

[1]University of British Columbia, Vancouver, Canada; [2]BC Women's Hospital and Health Centre, Vancouver, Canada; [3]Women's Health Research Institute, Vancouver, Canada

902 Low Prolactin and High 20αHSD May Contribute to cART-Induced P4 Deficits in Pregnancy

Eszter Papp; **Lena Serghides**
AAPH Team

Toronto General Research Institute, Toronto, Canada

TUESDAY, FEBRUARY 24, 2015

Session P-T10 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Immune Mechanisms in MTCT

903 Generating HIV Neutralization in Milk With Neutralizing IgG/dIgA Antibodies Infusion

Genevieve Fouda[1]; Josh Eudailey[1]; Erika Kunz[1]; Joshua Amos[1]; Jonathan Himes[1]; Lisa Colvin[1]; Xinyue Wang[2]; Keith Reimann[2]; Barton Haynes[1]; Sallie Permar[1]

[1]Duke University, Durham, NC, US; [2]University of Massachusetts Medical School, Boston, MA, US

904 Specificity of V3-specific Neutralizing Responses in HIV-1 Infected Women

David R. Martinez; Genevieve Fouda; Nathan Vandergrift; Celia LaBranch; David Montefiori; Xiaoying Shen; Thomas Denny; Georgia Tomaras; Sallie Permar

Duke Human Vaccine Institute, Durhamc, NC, US

905 Broad, Highly Avid Vaccine-Elicited Anti-V1V2 IgG Responses in HIV-Exposed Infants

Genevieve Fouda[1]; Coleen Cunningham[1]; Elizabeth McFarland[2]; Bill Borkowsky[3]; Nicole Yates[1]; Erin McGuire[1]; Hua-Xin Liao[1]; Barton Haynes[1]; Georgia Tomaras[1]; Sallie Permar[1]

[1]Duke University, Durham, NC, US; [2]University of Colorado, Aurora, CO, US; [3]New York University, New York, NY, US

906 Maternal Neutralization Escape Virus Variants Do Not Predict Infant HIV Infection Risk

Caitlin Milligan[1]; Maxwel Omenda[1]; Vrasha Chohan[1]; Katherine Odem-Davis[1]; Barbra A. Richardson[1]; Ruth W. Nduati[2]; Julie M. Overbaugh[1]

[1]Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US; [2]University of Nairobi, Nairobi, Kenya

Session P-T11 Poster Session — Poster Hall

2:30 pm – 4:00 pm

PMTCT-Associated Drug Resistance in Women and Infants

907 ART Failure and Resistance Among Pregnant and Post-Partum Women in South Africa

Christopher J. Hoffmann[1]; Silvia Cohn[1]; Fildah Mashabela[2]; Jennifer Hoffmann[1]; **Kelly E. Dooley**[1]; Richard E. Chaisson[1]; Neil Martinson[2]
the TSHEPISO Study Team

[1]Johns Hopkins University School of Medicine, Baltimore, MD, US; [2]Perinatal HIV Research Unit (PHRU), Johannesburg, South Africa

908 High Prevalence of HIV-1 Drug-Resistance Mutations in Subtype C Transmitting Mothers Detected Using 454 Ultra-Deep Sequencing

Johanna Ledwaba[1]; Anna Salimo[1]; Karl Technau[4]; Simon Travers[3]; Lynn Morris[1]; Gillian Hunt[1]; Louise Kuhn[2]

[1]National Institute for Communicable Diseases, National Health Laboratory Service, Sandringham, South Africa; [2]Columbia University, New York, NY, US; [3]University of the Western Cape, Modderdam, South Africa; [4]University of the Witwatersrand, Johannesburg, South Africa

909 NVP Resistance in Infants Infected by HIV-1 via Breastfeeding in the BAN Study

Julie A. Nelson[1]; Ali Fokar[1]; Michael G. Hudgens[1]; Kara J. Compliment[1]; Gerald Tegha[2]; Deborah Kamwendo[2]; Athena P. Kourtis[3]; Denise J. Jamieson[3]; Charles M. van der Horst[1]; Susan A. Fiscus[1]

[1]Univ of North Carolina at Chapel Hill, Chapel Hill, NC, US; [2]University of North Carolina Project–Malawi, Lilongwe, Malawi; [3]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US

Session P-U1 Poster Session **Poster Hall**

2:30 pm – 4:00 pm

HIV Diagnosis in Infants and Children

910 Birth HIV PCR Testing in South Africa: Diagnostic Challenges and Risk Factor Analysis

Karl-Günter Technau[1]; Louise Kuhn[2]; Lucia Hans[3]; Sergio Carmona[3]; Ashraf Coovadia[1]; Gayle Sherman[4]

[1]University of the Witwatersrand, Johannesburg, South Africa; [2]Columbia University, New York, NY, US; [3]National Health Laboratory Service, Johannesburg, South Africa; [4]National Institute for Communicable Diseases, Johannesburg, South Africa

911 System Gaps Result in Late Diagnosis and Treatment of Children With HIV in Hospital

Irene N. Njuguna[3]; Anjuli D. Wagner[1]; Vincent Otieno[3]; Lisa Cranmer[2]; Judy Adhiambo[3]; Sarah Benki-Nugent[1]; Elizabeth Maleche-Obimbo[3]; Jennifer A. Slyker[1]; Dalton Wamalwa[3]; Grace John-Stewart[1]

[1]University of Washington, Seattle, Kenya; [2]Emory University School of Medicine, Atlanta, GA, US; [3]University of Nairobi, Nairobi, Kenya

Session P-U2 Poster Session **Poster Hall**

2:30 pm – 4:00 pm

Early ART and HIV Persistence

912 Early Infant Antiretroviral Therapy Reduces Transcriptionally Active HIV Persistence

Gert U. van Zyl[1]; Margaret A. Bedison[2]; Anita Janse van Rensburg[3]; Barbara Laughton[3]; Mark F. Cotton[3]; John W. Mellors[2]

[1]Stellenbosch University and National Health Laboratory Service, Parow, South Africa; [2]University of Pittsburgh, Pittsburgh, PA, US; [3]Stellenbosch University and Tygerberg Academic Hospital, Cape Town, South Africa

WEDNESDAY, FEBRUARY 25, 2015

Session P-U3 Poster Session **Poster Hall**

2:30 pm – 4:00 pm

Treatment Outcomes Among Children and Youth With HIV

913 Immunodeficiency at the Start of ART in Children: A Global View

Klea Panayidou[1]; Ali Judd[3]

On behalf of the IeDEA Collaboration and the COHERE Collaboration

[1]University of Bern, Bern, Switzerland; [2]University of Copenhagen, Copenhagen, Denmark; [3]University College London, London, United Kingdom

914 Immune Recovery at 5 Years on ART in HIV+ Children From Four African Countries

Chloe A. Teasdale; Ruby Fayorsey; Zenebe Melaku; Duncan Chege; Catarina Casalini; Thresia Sebastian; **Elaine J. Abrams**

ICAP at Columbia University, New York, NY, US

915 Antiretroviral Therapy in Severely Malnourished, HIV-Infected Children in Asia

David C. Boettiger[1]; Linda Aurpibul[2]; Dina Muktiarti[3]; Siew Fong[4]; Pagakrong Lumbiganon[5]; Saphonn Vonthanak[6]; Nguyen Van Lam[7]; Rawiwan Hansudewechakul[8]; Azar Kariminia[1]

On behalf of TREAT Asia Pediatric HIV Observational Database

[1]University of New South Wales, Sydney, Australia; [2]Chiang Mai University, Chiang Mai, Thailand; [3]Cipto Mangunkusumo General Hospital, Jakarta, Indonesia; [4]Hospital Likas, Kota Kinabalu, Malaysia; [5]Khon Kaen University, Khon Kaen, Thailand; [6]National Centre for HIV/AIDS Dermatology and STDs, Phnom Penh, Cambodia; [7]National Hospital of Pediatrics, Hanoi, Viet Nam; [8]Chiangrai Prachanukroh Hospital, Chiang Rai, Thailand

916 Pubertal Development in HIV-Infected African Children on First-Line Antiretroviral Therapy

Mutsa F. Bwakura Dangarembizi

On behalf of the ARROW Trial Team

University of Zimbabwe, College of Health Sciences, Harare, Zimbabwe

917 Mortality of HIV-Infected Youth in the Combination Antiretroviral Therapy (cART) Era

Gayatri Mirani[1]; Paige L. Williams[2]; Miriam Chernoff[2]; Mark Abzug[6]; Myron Levin[3]; James Oleske[4]; George Seage[2]; Rohan Hazra[5]; Russell B. Van Dyke[1]

On behalf of the International Maternal Pediatric Adolsescent AIDS Clinical Trials (IMPAACT) Network P1074 Study Team

[1]Tulane University Health Sciences Center, New Orleans, LA, US; [2]Center for Biostatistics in AIDS Research Harvard School of Public Health, Boston, MA, US; [3]University of Colorado Anschutz Medical Campus, Aurora, CO, US; [4]Division of Pediatrics Allergy, Immunology & Infectious Diseases, Newark, NJ, US; [5]Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD, US; [6]University of Colorado School of Medicine and Children's Hospital Colorado, Aurora, CO, US; [7]IMPAACT Operations Center FHI 360, Durham, NC, US

918 Transition to Adult Units: Situation and Evolution of Vertically HIV Infected Youths in Spain

Talía Sainz[1]; Carolina Fernández McPhee[2]; Santiago Jimenez de Ory[1]; Maria Isabel Gonzalez-Tome[3]; Rafael Rubio[3]; Jose I Bernardino[4]; Santiago Moreno[2]; Jose Antonio Iribarren[5]; Belen Alejos[6]; Marisa Navarro[7]

On behalf of the Spanish Cohort of AIDS Research (CORIS) and the Pediatric Spanish Cohort of HIV-infected Children (CoRISpe)

[1]Hospital Universitario Gregorio Marañón, Madrid, Spain; [2]Hospital Universitario Ramon y Cajal, Madrid, Spain; [3]12 de Octubre Hospital, Madrid, Spain; [4]La Paz University Hospital, Madrid, Spain; [5]Hospital de Donostia, San Sebastian, Spain; [6]Centro Nacional de Epidemiología, ISCIII, Madrid, Spain; [7]Hospital Gregorio Marañon, Madrid, Spain

Session P-U4 Poster Session **Poster Hall**

2:30 pm – 4:00 pm

Treatment and Monitoring Strategies in Children

919 Long-Term Consequences of Planned Treatment Interruption in HIV-1–Infected Children

Riccardo Freguja[1]; Hahhah Poulson[2]; Paola Del Bianco[3]; Alexandra Compagnucci[4]; Yacine Saidi[4]; Carlo Giaquinto[5]; Lynda Harper[6]; Diana M. Gibb[6]; Nigel J. Klein[2]; Anita De Rossi[1]

[1]1 AIDS Reference Center, Section of Oncology and Immunology, Padova, Italy; [2]Institute of Child Health, London, United Kingdom; [3]Istituto Oncologico Veneto-IRCCS, Padova, Italy; [4]Inserm SC10, Paris, France; [5]Department of Mother and Child Health, Padova, Italy; [6]Medical Research Council, London, United Kingdom

920 Can CD4 Monitoring in Virologically Suppressed Children be Reduced or Stopped?

Mary-Ann Davies[1]; Helena Rabie[2]; Geoff Fatti[3]; Kathryn Stinson[1]; **Karl-Günter Technau**[4]; Shobna Sawry[5]; Brian Eley[6]; Lynne Mofenson[7]; Andrew Boulle[1]; IeDEA Southern Africa[8]

[1]University of Cape Town, Cape Town, South Africa; [2]University of Stellenbosch, Cape Town, South Africa; [3]Kheth'Impilo, Cape Town, South Africa; [4]University of the Witwatersrand, Johannesburg, South Africa; [5]University of Witwatersrand, Johannesburg, South Africa; [6]University of Cape Town, Cape Town, South Africa; [7]Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD, US; [8]Univeristy of Cape Town and University of Bern, Cape Town, South Africa

TUESDAY, FEBRUARY 24, 2015

Session P-U5 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Determinants of Disease Progression in Children

921 Impact of Sex Differences on Disease Outcome in Pediatric HIV in South Africa

Masahiko Mori[1]; Emily Adland[1]; Alice Swordy[1]; Maximilian Muenchhoff[1]; Nora Lavandier[1]; Jacob Hurst[1]; Thumbi Ndung'u[2]; Andy Prendergast[3]; Philip J. Goulder[1]; Pieter Jooste[4]

[1]University of Oxford, Oxford, United Kingdom; [2]University of KwaZulu-Natal, Durban, South Africa; [3]Queen Mary University of London, London, United Kingdom; [4]Kimberley Hospital, Durban, South Africa

922 CD31 Expression on CD4 Cells Predicts Clinical Course of HIV in a Perinatally HIV-Infected Cohort

Ramia Zakhour[1]; Gilhen Rodriguez[2]; Cynthia Bell[2]; Guenet Degaffe[2]; Laura Benjamins[2]; Gabriela DelBianco[2]; Elizabeth Donnachie[2]; Tran Dat[2]; Gloria P. Heresi[2]; James R. Murphy[2]

[1]University of Texas, Houston, TX, US; [2]UTHealth Medical School, Houston, TX, US

923 Premature Aging and Immune Senescence in HIV-1-Infected Children

Ketty Gianesin[1]; Antoni Noguera-Julian[2]; Marisa Zanchetta[3]; Osvalda Rampon[1]; Clàudia Fortuny[2]; Mireia Camós[2]; Carlo Giaquinto[1]; Anita De Rossi[1]

[1]University of Padova, Padova, Italy; [2]Hospital Sant Joan de Déu-Universitat de Barcelona, Barcelona, Spain; [3]Istituto Oncologico Veneto–IRCCS, Padova, Italy

924 *KIR/HLA* Alleles Alter CD4$^+$ Lymphocyte Count and Viral Load in HIV-Infected Children

Kumud Singh[1]; Min Qin[2]; Sean Brummel[2]; Konstantia Angelidou[2]; Rodney Trout[1]; Terrence Fenton[2]; Stephen Spector[1]

[1]University of California San Diego, La Jolla, CA, US; [2]Harvard School of Public Health, Boston, MA, US

THURSDAY, FEBRUARY 26, 2015

Session P-U6 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Complications of HIV and ART: Pulmonary and Cardiovascular Outcomes

925 Arterial Stiffness in HIV+ Youth and Associations With HIV-Related Variables

Allison R. Eckard[1]; Julia C. Rosebush[1]; Mary Ann O'Riordan[2]; Christopher T. Longenecker[2]; Bridget Wynn[1]; Monika Uribe Leitz[1]; Danielle Labbato[2]; Norma Storer[2]; Bruce Kinley[2]; Grace A. McComsey[2]

[1]Emory University School of Medicine, Atlanta, GA, US; [2]Case Western Reserve University, Cleveland, OH, US

926 Does Early ART Normalize Pulse-Wave Velocity in Children? Evidence From CHER Cohort

Steve Innes[1]; Zukiswa Magogotya[1]; Philip Herbst[1]; Mark F. Cotton[1]; Barbara Laughton[1]; Sara Browne[2]; Richard Haubrich[2]

[1]Stellenbosch University, Cape Town, South Africa; [2]University of California San Diego, San Deigo, CA, US

927 The Impact of HIV and ART on Markers of Inflammation, Vascular Injury and Disordered Thrombogenesis in Children

Julia M. Kenny[1]; Sarah Walker[1]; Adrian Cook[1]; Victor Musiime[2]; Priscilla Wavamunno[2]; Florence Odongo[2]; Grace Mirembe[2]; Dorica Masaku[3]; Diana M. Gibb[1]; Nigel J. Klein[1]

[1]University College London, London, United Kingdom; [2]Joint Clinical Resarch Centre, Kampala, Uganda; [3]University Teaching Hospital, Lusaka, Zambia

928 T-Cell Activation and E-Selectin Associated With Coronary Plaque in HIV-Infected Youth

Julia B. Purdy; Aylin Unsal; Khaled Abd-Elmoniem; Adam Rupert; Joseph A. Kovacs; Rohan Hazra; Ahmed Gharib; Colleen Hadigan

National Institutes of Health, Bethesda, MD, US

929 High Prevalence of Dyslipidemia and Insulin Resistance in African Children on ART

Steve Innes[1]; Kameelah L. Abdullah[2]; Richard Haubrich[2]; Sara Browne[2]; Mark F. Cotton[1]

[1]Stellenbosch University, Cape Town, South Africa; [2]University of California San Diego, San Deigo, CA, US

930 Growth and Lipid Profiles in a South African Cohort of HIV$^+$ Children and HIV$^-$ Controls

Sarah Ramteke[1]; Stephanie Shiau[1]; Marc Foca[1]; Renate Strehlau[2]; Francoise Pinillos[2]; Faeezah Patel[2]; Avy Violari[3]; Afaaf Liberty[3]; Stephen M. Arpadi[1]; Louise Kuhn[1]

[1]Columbia University, New York, NY, US; [2]University of the Witwatersrand, Johannesburg, South Africa; [3]University of Witwatersrand, Johannesburg, South Africa

Session P-U7 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Complications of HIV and ART: Bones, Brains, and Kidneys

931 Vitamin D Status and Bone Outcomes in Perinatally HIV-Infected Children

Denise L. Jacobson[1]; Mitchell Geffner[2]; Charles B. Stephensen[3]; Rohan Hazra[4]; Kunjal Patel[8]; Tracie L. Miller[5]; Russell B. Van Dyke[6]; Angela Ellis[9]; Linda A. DiMeglio[7]
For the Pediatric HIV/AIDS Cohort Study

[1]Harvard School of Public Health, Center for Biostatistics in AIDS Research, Boston, MA, US; [2]Children's Hospital Los Angeles, Keck School of Medicine, Los Angeles, CA, US; [3]USDA, Davis, CA, US; [4]Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, MD, US; [5]University of Miami, Miami, FL, US; [6]Tulane University School of Medicine, New Orleans, LA, US; [7]Indiana University, School of Medicine, Indianapolis, IN, US; [8]Harvard School of Public Health, Boston, MA, US; [9]Frontier Science and Research Foundation, Amherst, NY, US

932 Bone Quality by Ultrasonometry in South African HIV+ Children and HIV- Controls

Stephen M. Arpadi[1]; Stephanie Shiau[1]; Renate Strehlau[2]; Francoise Pinillos[2]; Faeezah Patel[2]; Louise Kuhn[1]; Ashraf Coovadia[2]; Sarah Ramteke[1]; Jonathan Kaufman[3]; Michael T. Yin[1]

[1]Columbia University, New York, NY, US; [2]University of the Witwatersrand, Johannesburg, South Africa; [3]Mount Sinai School of Medicine, New York, NY, US

933 APOL1 Gene Variants and Chronic Kidney Disease in Perinatally HIV-Infected Youth

Murli Purswani[1]; Kunjal Patel[2]; Cheryl Winkler[3]; Stephen Spector[4]; Rohan Hazra[5]; George Seage[2]; Lynne Mofenson[5]; Gwendolyn Scott[6]; Russell Van Dyke[7]; Jeffrey Kopp[8]
For the Pediatric HIV/AIDS Cohort Study (PHACS)

[1]Albert Einstein College of Medicine, Bronx, NY, US; [2]Harvard School of Public Health, Boston, MA, US; [3]National Cancer Institute (NCI), Bethesda, MD, US; [4]University of California San Diego, San Diego, CA, US; [5]Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD, US; [6]University of Miami, Miami, FL, US; [7]Tulane University, New Orleans, LA, US; [8]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD, US

934 Cystatin C Is a Marker for Both Inflammation and Renal Function in HIV+ Children

Àngela Deyà-Martínez[1]; **Clàudia Fortuny**[1]; Pere Soler-Palacín[2]; Olaf Neth[3]; Emilia Sánchez[4]; Andrea Martín-Nalda[2]; Lola Falcón-Neyra[3]; Anna Vila[1]; Anna Valls[1]; Antoni Noguera-Julian[1]

[1]Hospital Sant Joan de Déu, Esplugues, Spain; [2]Hospital Vall d'Hebrón, Barcelona, Spain; [3]Hospital Virgén del Rocío, Sevilla, Spain; [4]Universitat Ramon Llull, BArcelona, Spain

935 Cognitive Performance and Intracerebral Findings in Perinatally HIV-Infected Children

Sophie Cohen[1]; Matthan W. Caan[2]; Jacqueline A. ter Stege[3]; Henriette J. Scherpbier[1]; Taco W. Kuijpers[1]; Peter Reiss[2]; Gert J. Geurtsen[2]; Charles B. Majoie[2]; Ben Schmand[2]; Dasja Pajkrt[1]

[1]Emma Children's Hospital AMC, Amsterdam, Netherlands; [2]Academic Medical Center University of Amsterdam, Amsterdam, Netherlands; [3]Emma Children's Hospital, Amsterdam, Netherlands

936 Executive Functions Among Perinatally HIV-Exposed and HIV-Infected Youth

Sharon L. Nichols[1]; Miriam Chernoff[2]; Kathleen M. Malee[3]; Patricia A. Sirois[4]; Paige L. Williams[2]; Betsy L. Kammerer[5]
the Memory Substudy Team of the Pediatric HIV/AIDS Cohort Study (PHACS)

[1]University of California, San Diego, La Jolla, CA, US; [2]Harvard School of Public Health, Center for Biostatistics in AIDS Research, Boston, MA, US; [3]Northwestern University Feinberg School of Medicine, Chicago, IL, US; [4]Tulane University School of Medicine, New Orleans, LA, US; [5]Children's Hospital Boston, Boston, MA, US

937 Sleep Disturbances in a Cohort of HIV-Infected Children and Adolescents on Antiretroviral Treatment: NeuroCoRISpeS

Cristina García-Navarro[1]; Santiago Jiménez de Ory[2]; Maria Luisa Navarro Gomez[2]; José Tomás Ramos Amador[6]; Maria Jose Mellado[3]; Luis Prieto[5]; Pablo Rojo Conejo[1]; Esmeralda Nuñez[4]; **María Isabel González-Tomé**[1]
On behalf of the CoRISpeS,ÄìMadrid Cohort

[1]Hospital Universitario 12 de Octubre, Madrid, Spain; [2]Hospital Universitario Gregorio Marañón, Madrid, Spain; [3]Hospital Universitario La Paz, Madrid, Spain; [4]Hospital Regional Universitario Carlos Haya, Malaga, Spain; [5]Hospital Universitario de Getafe, Getafe, Spain; [6]Hospital Universitario Clinico San Carlos, Madrid, Spain; [7]Madrid, Madrid, Spain

WEDNESDAY, FEBRUARY 25, 2015

Session P-U8 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Tuberculosis and Other Coinfections in Children With HIV

938 Tuberculosis Among Children on Antiretroviral Therapy in Swaziland, 2004-2012

Melissa A. Briggs[1]; Andrew Auld[1]; Harrison Kamiru[2]; Harriet Nuwagaba-Biribonwoha[2]; Velephi Okello[3]; George Bicego[1]; Andrew L. Baughman[1]; Simon Agolory[1]; Tedd V. Ellerbrock[1]; Peter Ehrenkranz[4]

[1]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US; [2]Mailman School of Public Health, New York, NY, US; [3]Swaziland Ministry of Health, Mbabane, Swaziland; [4]US Centers for Disease Control and Prevention (CDC), Mbabane, Swaziland

939 Mycobacterium TB Disease in HIV-Infected Children Receiving LPV/r or NVP-Based ART

Moherndran Archary[1]; Linda Barlow-Mosha[2]; Avy Violari[3]; Jane Lindsey[4]; Lynne Mofenson[4]; Patrick Jean-Philipe[4]; Bonnie Zimmer[4]; Paul E Palumbo[5]

[1]University of KwaZulu-Natal, Durban, South Africa; [2]MUJHU Care Ltd/MUJHU Research Collaboration, Kampala, Uganda; [3]Perinatal HIV Research Unit, Johannesburg, South Africa; [4]Frontier Science, Amherst, NY, US; [5]Geisel School of Medicine at Dartmouth, Lebanon, NH, US

940 Safety of Rifabutin in HIV/TB-Coinfected Children on Protease Inhibitor-Based ART

Holly E. Rawizza[1]; Kristin M. Darin[2]; Kimberly K. Scarsi[3]; Biobele Brown[4]; Regina Oladokun[4]; Nkiru David[5]; Sulaimon Akanmu[6]; Oluremi Olaitan[7]; Prosper Okonkwo[7]; Phyllis Kanki[8]
On behalf of the APIN PEPFAR Team

[1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, US; [2]Northwestern University, Feinberg School of Medicine, Chicago, IL, US; [3]University of Nebraska Medical Center, Omaha, NE, US; [4]University College Hospital, Ibadan, Nigeria; [5]National Institute of Medical Research, Lagos, Nigeria; [6]Lagos University Teaching Hospital, Lagos, Nigeria; [7]AIDS Prevention Initiative in Nigeria, Abuja, Nigeria; [8]Harvard School of Public Health, Boston, MA, US

941 Skin Complaints in African Children Randomized to Stop or Continue Cotrimoxazole

Andrew Prendergast[1]; Mutsa F. Bwakura Dangarembizi[2]; Peter Mugyenyi[3]; Joseph Lutaakome[4]; Adeodata Kekitiinwa[5]; Diana M. Gibb[6]; Sarah Walker[6]
On behalf of the ARROW Trial Team

[1]Queen Mary University of London, London, United Kingdom; [2]University of Zimbabwe, College of Health Sciences, Harare, Zimbabwe; [3]JCRC, Kampala, Uganda; [4]MRC/UVRI Uganda Research Unit on AIDS, Entebbe, Uganda; [5]Baylor-Uganda, Kampala, Uganda; [6]MRC Clinical Trials Unit at University College London, London, United Kingdom

942 Disease Progression and Response to Treatment in Vertically HIV/HVC Co-infected Patients

Talía Sainz[1]; Carolina Fernández McPhee[2]; Santiago Jimenez de Ory[1]; Pablo Rojo[3]; Maria del Carmen Otero[4]; Milagros Garcia Lopez-Hortelano[5]; Olaf Neth[7]; Jose Beceiro[8]; Maribel González Tomé[3]; María Luisa Navarro[6]
On behalf of the Spanish Cohort of HIV-Infected Children and Adolescents (CoRISpe)

[1]Hospital Universitario Gregorio Marañón, Madrid, Spain; [2]Hospital Ramón y Cajal, SEIM-Gesida, Madrid, Spain; [3]Hospital 12 de Octubre, Madrid, Spain; [4]Hospital La Fe, Valencia, Spain; [5]Hospital La Paz, Madrid, Spain; [6]Hospital Gregorio Marañón, Madrid, Spain; [7]Hospital Virgen del Rocio, Sevilla, Spain; [8]Hospital de Alcalá, Alcalá de Henares, Spain

943 Human Papillomavirus and Cervical Cytology in Perinatally Infected Asian Adolescents

Annette H. Sohn[1]; Stephen J. Kerr[2]; Rawiwan Hansudewechakul[3]; Wasana Prasitsuebsai[2]; Kulkanya Chokephaibulkit[4]; Truong V. Nguyen[5]; Thoa P. Le[6]; Thida Singtoroj[1]; Nittaya Phanuphak[7]; HPV in Adolescents Study[1]

[1]TREAT Asia/amfAR – The Foundation for AIDS Research, Bangkok, Thailand; [2]HIV-NAT/Thai Red Cross AIDS Research Centre, Bangkok, Thailand; [3]Chiangrai Prachanukroh Hospital, Chiang Rai, Thailand; [4]Siriraj Hospital, Mahidol University, Bangkok, Thailand; [5]Hung Vuong Hospital, Ho Chi Minh City, Viet Nam; [6]Children's Hospital 1, Ho Chi Minh City, Viet Nam; [7]SEARCH, Thai Red Cross AIDS Research Centre, Bangkok, Thailand

944 Sexually Transmitted Infections in Youth With Controlled and Uncontrolled HIV

Andres F. Camacho-Gonzalez[1]; Miriam C. Chernoff[2]; Paige L. Williams[2]; Ann Chahroudi[1]; James M. Oleske[3]; Rana Chakraborty[1]; Shirley Traite[2]; Murli U. Purswani[4]; Mark J. Abzug[5]
On behalf of the IMPAACT P1074 Study Team

[1]Emory University School of Medicine, Atlanta, GA, US; [2]Harvard School of Public Health, Center for Biostatistics in AIDS Research, Boston, MA, US; [3]Rutgers New Jersey Medical School, Newark, NJ, US; [4]Albert Einstein College of Medicine, Division of Pediatric Infectious Diseases, Bronx Lebanon Hospital Center, Bronx, NY, US; [5]University of Colorado School of Medicine, Division of Pediatric Infectious Diseases, Aurora, CO, US; [6]International Maternal Pediatric Adolescent AIDS Clinical Trials, Durham, NC, US

TUESDAY, FEBRUARY 24, 2015

Session P-U9 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Responses to Vaccines in Children

945 Sustained Responses to Measles Revaccination in HIV-Infected Children on ART in Kenya

Laura Newman[1]; Anne Njoroge[1]; Bhavna Chohan[1]; Amalia Magaret[1]; Jonathan Gorstein[1]; Julie M. Overbaugh[2]; Dalton Wamalwa[3]; Elizabeth M. Obimbo[3]; Ruth W. Nduati[3]; Carey Farquhar[1]

[1]University of Washington, Seattle, WA, US; [2]Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US; [3]University of Nairobi, Nairobi, Kenya

946 T-Cell Anergy and Activation Are Associated With Suboptimal Humoral Responses to Measles Revaccination in HIV-Infected Children on Antiretroviral Therapy in Nairobi, Kenya

Matthew B. Buechler[1]; Laura Newman[2]; Bhavna Chohan[3]; Anne Njorge[5]; Dalton Wamalwa[6]; Carey Farquhar[3]

[1]University of Washington, Seattle, WA, US; [2]University of Washington, Seattle, WA, US; [3]University of Washington, Seattle, WA, US; [4]Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US; [5]Kenyatta National Hospital, Nairobi, Kenya; [6]University of Nairobi, Nairobi, Kenya

947 Molecular Profiles of CXCR5+ CD4 Memory T Cells Associated With Flu Vaccine Response

Lesley R. de Armas[1]; Nicola Cotugno[1]; Suresh Pallikkuth[1]; Alberto Cagigi[3]; Paolo Palma[2]; Paolo Rossi[2]; Savita Pahwa[1]

[1]University of Miami Miller School of Medicine, Miami, FL, US; [2]Children's Hospital Bambino Gesu, Rome, Italy; [3]Children Hospital Bambino Gesu, Rome, Italy

948 The Potential of BCG and HIV-TB Vaccines to Exacerbate HIV-1 Pathogenesis in Infants

Kara Jensen[1]; Koen K. Van Rompay[2]; William R. Jacobs[3]; Glenn Fennelly[3]; Katie Mollan[1]; Michael G. Hudgens[1]; Mike Piatak[4]; Michelle H. Larsen[3]; Kristina De Paris[1]

[1]University of North Carolina, Chapel Hill, NC, US; [2]California National Primate Research Center, University of California, Davis, CA, US; [3]Albert Einstein College of Medicine, New York, NY, US; [4]Frederick National Laboratory, Frederick, MD, US

Session P-U10 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Pharmacokinetics, Safety, and Efficacy of ART in Children and Youth

949 Prediction of ARV Drug Clearance in Children

Frantz Foissac; Naïm Bouazza; Elodie Valade; Mailys De Sousa; Floris Fauchet; Sihem Benaboud; Deborah Hirt; Stéphane Blanche; Saïk Urien; Jean-Marc Treluyer

EA 08 Université Paris Descartes, Sorbonne Paris Cité, Unité de Recherche Clinique, AP-HP, Hôpital Tarnier, Paris, France, Paris, France

950 Use of Maraviroc in HIV-1-Infected Paediatric Patients in Clinical Practice

Claudia Palladino[1]; Maria Luisa Navarro Gomez[6]; Pere Soler-Palacín[5]; Maria Isabel Gonzalez-Tome[7]; Santiago Jimenez de Ory[6]; Maria Espiau[5]; Juan Antonio León-Leal[4]; Clàudia Fortuny[3]; Verónica Briz[2]
CoRISpe working group

[1]University of Lisbon, Lisbon, Portugal; [2]National Center for Microbiology, Madrid, Spain; [3]Hospital Sant Joan de Déu, Universitat de Barcelona, Barcelona, Spain; [4]Hospital Infantil Universitario Virgen del Rocío, Seville, Spain; [5]Hospital Universitari Vall d'Hebron, Barcelona, Spain; [6]Hospital General Universitario Gregorio Marañón, Madrid, Spain; [7]Hospital Universitario Doce de Octubre, Madrid, Spain

951 Safety and Pharmacokinetics of Elvitegravir in HIV-1 Infected Pediatric Subjects

Joseph M. Custodio[1]; Victor Musiime[2]; Aditya Gaur[3]; Elizabeth McFarland[4]; Wasana Prasitsuebsai[5]; Lize Hellstrom[6]; Xuelian Wei[1]; Rebecca Begley[1]; Srinivasan Ramanathan[1]; Sean R. Bennett[1]

[1]Gilead Sciences, Inc., Foster City, CA, US; [2]Joint Clinical Research Centre, Kampala, Uganda; [3]St. Jude Children's Research Hospital, Memphis, TN, US; [4]University of Colorado Denver, Aurora, CO, US; [5]HIV - NAT, Bangkok, Thailand; [6]Be Part Yoluntu Centre, Cape Town, South Africa

952 Lack of Emergent Resistance in HIV-1-Infected Adolescents on Elvitegravir-Based STRs

Danielle P. Porter; Sean R. Bennett; Erin Quirk; Michael D. Miller; Kirsten L. White

Gilead Sciences, Inc., Foster City, CA, US

953 Week-24 Data From a Phase 3 Clinical Trial of E/C/F/TAF in HIV-Infected Adolescents

Hilda Kizito[2]; Aditya Gaur[3]; Wasana Prasitsuebsai[4]; Natella Rakhmanina[5]; Eileen Lawson[1]; Yongwu Shao[1]; **Sean R. Bennett**[1]; Andrew Cheng[1]; Erin Quirk[1]

[1]Gilead Sciences, Inc., Foster City, CA, US; [2]Joint Clinical Research Centre, Kampala, Uganda; [3]St Jude Children's Research Hospital, Memphis, TN, US; [4]HIV Netherlands Australia Thailand Research Collaboration, Bangkok, Thailand; [5]Children's National Health System, Washington, DC, US

954 Efficacy and Safety of Long-Term Tenofovir DF (TDF) Therapy in HIV-Infected Children

Xavier Saez-Llorens[2]; Jaime G. Deville[3]; Ayesha Mirza[4]; Janet S. Chen[5]; Aditya Gaur[6]; Mobeen Rathore[4]; Dana Hardin[7]; Ya-Pei Liu[1]; **Erin Quirk**[1]
GS-US-104-0352 Study Team

[1]Gilead Sciences, Inc., Foster City, CA, US; [2]Hospital del Niño, Panama City, Panama; [3]University of California Los Angeles, Los Angeles, CA, US; [4]University of Florida, Jacksonville, FL, US; [5]Drexel University College of Medicine, Philadelphia, PA, US; [6]St Jude Children's Research Hospital, Memphis, TN, US; [7]Eli Lilly, Indianapolis, IN, US

955 Acceptability of Lopinavir/r Minitabs, Tablets and Syrups in HIV-Infected Children

Adeodata Kekitiinwa
CHAPAS-2

Baylor College of Medicine Children's Foundation Uganda, Kampala, Uganda

956 Therapeutic Drug Monitoring of Lopinavir in HIV-Infected Children on Second-Line ART

Linda Aurpibul[1]; Wasana Prasitsuebsai[2]; Tavitiya Sudjaritruk[3]; Pope Kosalaraksa[4]; Nia Kurniati[6]; Khanh Huu Truong[5]; Viet Chau Do[7]; Sirinya Teeraananchai[2]; Stephen J. Kerr[2]
the TASER-Pediatrics Study Group

[1]Research Institute for Health Sciences, Chaing Mai University, Chiang Mai, Thailand; [2]The HIV Netherlands Australia Thailand Research Collaboration, The Thai Red Cross AIDS Research Centre, Bangkok, Thailand; [3]Department of Pediatrics, Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand; [4]Srinagarind Hospital, Khon Kaen University, Khon Kaen, Thailand; [5]Children's Hospital 1, Ho Chi Minh City, Viet Nam; [6]Cipto Mangunkusumo General Hospital, Jakarta, Indonesia; [7]Children's Hospital 2, Ho Chi Minh City, Viet Nam

WEDNESDAY, FEBRUARY 25, 2015

Session P-V1 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Postexposure Prophylaxis (PEP)

957 Significant Intolerability of Efavirenz in HIV Occupational Postexposure Prophylaxis

Surasak Wiboonchutikul[1]; Varaporn Thientong[1]; Patama Sutha[1]; Boonchai Kowadisaiburana[2]; Weerawat Manosuthi[1]

[1]Bamrasnaradura Infectious Diseases Institute, Nonthaburi, Thailand; [2]Bangkok Hospital, Bangkok, Thailand

958 Rilpivirine-Emtricitabine-Tenofovir for HIV Nonoccupational Postexposure Prophylaxis

Rosalind Foster[1]; John McAllister[2]; Tim R. Read[3]; Anna Pierce[4]; Robyn Richardson[2]; Anna McNulty[1]; Andrew Carr[2]
On behalf of the EPEP Study Researchers

[1]Sydney Sexual Health Centre, Sydney, Australia; [2]St Vincent's Centre for Applied Medical Research, Sydney, Australia; [3]Melbourne Sexual Health Centre, Melbourne, Australia; [4]The Alfred Hospital, Melbourne, Australia

959 Tenofovir/Emtricitabine Plus LPV/r vs MVC or Raltegravir for PEP: 2 Randomized Trials

Lorna Leal; Agathe Leon; Berta Torres; Alexy Inciarte; Constanza Lucero; Josep Mallolas; Maria Martinez-Rebollar; Ana González-Cordón; Jose M. Gatell; Felipe Garcia

Hospital Clínic Barcelona, Barcelona, Spain

960 Effects of Three Regimens of PEP on the Immune System of HIV-Seronegative Individuals

Alberto C. Guardo[1]; Lorna Leal[2]; Agathe Leon[2]; Cristina Rodriguez de Miguel[2]; Manel E. Bargallo[1]; Cristina Rovira[1]; Josep Llach[2]; Jose M. Gatell[2]; Felipe Garcia[2]; Montserrat Plana[1]

[1]L'Institut D'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain; [2]Hospital Clinic, Barcelona, Spain

961 Management of Acute HIV After Initiation of Postexposure Prophylaxis: Challenges and Lessons Learned

Goli Haidari[1]; Naomi Fitzgerald[4]; Sonia Raffe[2]; Nneka Nwokolo[3]; Olamide Dosekun[1]; Mark D. Lawton[5]; Nickie Mackie[1]; Julie Fox[4]; Martin Fisher[2]; Sarah Fidler[1]

[1]St Mary's Hospital–Imperial College Healthcare NHS Trust, London, United Kingdom; [2]Brighton and Sussex Hospitals NHS Trust, Brighton, United Kingdom; [3]Chelsea and Westminster Hospital NHS Foundation Trust, London, United Kingdom; [4]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; [5]The Royal Liverpool and Broadgreen University Hospitals NHS Trust, Liverpool, United Kingdom; [6]St Mary's Hospital–Imperial College Healthcare NHS Trust, London, United Kingdom; [7]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; [8]Brighton and Sussex Hospitals NHS Trust, Brighton, United Kingdom; [9]St Mary's Hospital–Imperial College Healthcare NHS Trust, London, United Kingdom

THURSDAY, FEBRUARY 26, 2015

Session P-V2 Poster Session — Poster Hall

2:30 pm – 4:00 pm

PrEP and Microbicide Challenge

962 FTC/TDF Prevents SHIV Infection in *C trachomatis* and *T vaginalis*-Infected Macaques

Jessica Radzio; Tara Henning; James Mitchell; Angela Holder; Debra Hanson; Janet McNicholl; Walid Heneine; John Papp; Ellen Kersh; Gerardo Garcia-Lerma

US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US

963 Impact of Sexually Transmitted Infections on the Efficacy of Tenofovir Vaginal Gel in Macaques

Natalia Makarova; Tara Henning; Andrew Taylor; Chuong Dinh; Carol Farshy; Janet McNicholl; John Papp; Walid Heneine; Ellen Kersh; **Charles W. Dobard**

US Centers for Disease Control and Prevention, Atlanta, GA, US

964 Oral Single-Dose Maraviroc Does Not Prevent Ex Vivo HIV Infection of Rectal Mucosa in Healthy HIV-1–Negative Human Volunteers in Tissue Explants.

Josep Coll[2]; José Moltó[2]; Jaume Boix[3]; Laura Else[4]; Elisabet Garcia[1]; Roger Paredes[2]; David Back[4]; Bonaventura Clotet[5]; **Cecilia Cabrera**[1]

[1]Institut de Recerca de la Sida IrsiCaixa, Institut d'Investigació en Ciències de la Salut Germans Trias i Pujol, Barcelona, Spain; [2]Fundació Lluita Contra la SIDA, Institut d'Investigació en Ciències de la Salut Germans Trias i Pujol, Barcelona, Spain; [3]Unidad de Endoscopia Digestiva. Hospital Universitario Germans Trias i Pujol, Barcelona, Spain; [4]Pharmacology Research Laboratories, Liverpool, United Kingdom; [5]Fundació Lluita Contra la SIDA-IRSICAIXA, VIC-UCC (Universitat de Vic-Universitat Central de Catalunya), Barcelona, Spain

965 CCR5 Blockade With Maraviroc Does Not Prevent SIVmac Oral Transmission to Macaques

Egidio Brocca-Cofano[1]; Cuiling Xu[1]; Dongzhu Ma[1]; Benjamin Policicchio[1]; Kevin Raehtz[1]; Tammy Dunsmore[1]; George Richter-Haret[1]; Brandon F. Keele[2]; Ivona Pandrea[1]; Cristian Apetrei[1]

[1]University of Pittsburgh, Pittsburgh, PA, US; [2]National Cancer Institute (NCI), Frederick, MD, US

966LB Correlation of In Vivo Cabotegravir Concentration and Prevention of SIV in Macaques

William R. Spreen[4]; Anabel Lowry[1]; Ranajit Pal[2]; Yun Lan Yueh[4]; Susan Ford[4]; Nicola Richardson-Harman[3]; Jim A. Turpin[1]; Fulvia Veronese[1]; **James E. Cummins**[1]
ABL/BIOQUAL NHP Team

[1]National Institutes of Health, Bethesda, MD, US; [2]Advanced Bioscience Laboratories, Inc, Rockville, MD, US; [3]Alpha StatConsult LLC, Damascus, MD, US; [4]GlaxoSmithKline, Durham, NC, US

967 MZC Gel Inhibits Ex Vivo HIV-1 and HSV-2 Infection in Human Cervical Mucosa

Guillermo Villegas; Giulia Calenda; Patrick Barnable; Keith Levendosky; Michael Cooney; José Fernández-Romero; Thomas Zydowsky; Natalia Teleshova

Population Council, New York, NY, US

968 GRFT/Carrageenan Gel Inhibits SHIV-RT and HSV-2 Infection in Macaque Vaginal Mucosa

Giulia Calenda[1]; Patrick Barnable[1]; Keith Levendosky[1]; Kyle Kleinbeck[1]; Agegnehu Gettie[2]; James Blanchard[4]; José Fernández-Romero[1]; Barry O'Keefe[3]; Thomas Zydowsky[1]; Natalia Teleshova[1]

[1]Population Council, New York, NY, US; [2]Aaron Diamond AIDS Research Center, New York, NY, US; [3]National Cancer Institute (NCI), Fredrick, MD, US; [4]Tulane University, Covington, LA, US

TUESDAY, FEBRUARY 24, 2015

Session P-V3 Poster Session — Poster Hall

2:30 pm – 4:00 pm

PrEP: Uptake

969 Sustained PrEP Use Among High-Risk African HIV Seroincident Couples Participating in a PrEP Demonstration Project

Renee Heffron[1]; Kenneth Ngure[2]; Nulu Bulya Semiyaga[3]; Josephine Odoyo[4]; Edna Tindimwebwa[5]; Jennifer Morton[1]; Lara Kidoguchi[1]; Mark A. Marzinke[6]; Connie Celum[1]; Jared Baeten[1]
Partners Demonstration Project Team

[1]University of Washington, Seattle, WA, US; [2]Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya; [3]Makerere University College of Health Sciences, Kampala, Uganda; [4]Kenya Medical Research Institute, Nairobi, Kenya; [5]Kabwohe Clinic Research Center, Kabwohe, Uganda; [6]Johns Hopkins University School of Medicine, Baltimore, MD, US

970 PrEP Engagement for HIV Prevention: Results From the iPrEx Open Label Extension (OLE)

David V. Glidden[6]; Susan P. Buchbinder[1]; Peter L. Anderson[2]; Vanessa McMahan[3]; K. Rivet Amico[4]; Albert Liu[1]; Sybil Hosek[5]; Megha Mehrotra[6]; Robert M. Grant[3]
iPrEx Investigators

[1]San Francisco Department of Public Health, San Francisco, CA, US; [2]University of Colorado, Denver, CO, US; [3]Gladstone Institute, San Francisco, CA, US; [4]University of Michigan, Ann Arbor, MI, US; [5]John Stronger Hospital, Chicago, IL, US; [6]University of California San Francisco, San Francisco, CA, US

971 Preliminary Follow-up of Injecting Drug Users Receiving Preexposure Prophylaxis

Michael T. Martin[1]; Suphak Vanichseni[2]; Pravan Suntharasamai[2]; Udomsak Sangkum[2]; Philip Mock[1]; Manoj Leethochawalit[3]; Sithisat Chiamwongpaet[3]; Somyot Kittimunkong[4]; Marcel Curlin[1]; Kachit Choopanya[2]

[1]US Centers for Disease Control and Prevention (CDC), Nonthaburi, Thailand; [2]Bangkok Tenofovir Study Group, Bangkok, Thailand; [3]Bangkok Metropolitan Administration, Bangkok, Thailand; [4]Ministry of Public Health, Nonthaburi, Thailand

972 Recent Increases in PrEP Utilization at a Boston Community Health Center Among Men Who Have Sex With Men, 2011-2014: Transition From Research to Clinical Practice

Kenneth H. Mayer[1]; Kenneth Levine[1]; Chris Grasso[1]; Douglas S. Krakower[1]; Matthew Mimiaga[2]

[1]Fenway Health, Boston, MA, US; [2]Harvard School of Public Health, Boston, MA, US

973 Barriers to Effective Prevention: Applying a PrEP Care Continuum to a US Cohort of Black and White MSM

Colleen F. Kelley; Erin M. Kahle; Aaron Siegler; Carlos del Rio; Travis Sanchez; Patrick Sullivan; Eli S. Rosenberg

Emory University, Atlanta, GA, US

974 Provider Prescription of Preexposure Prophylaxis (PrEP) for HIV Infection

Shikha Garg; John Weiser; Linda Beer; Jacek Skarbinski

US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US

Session P-V4 Poster Session — Poster Hall

2:30 pm – 4:00 pm

PrEP: Measures and Correlates of Adherence

975 Urine Assay for Tenofovir to Monitor Adherence to Tenofovir-Emtricitabine as PrEP

Helen C. Koenig[1]; Karam Mounzer[1]; **Giffin W. Daughtridge**[1]; Caroline E. Sloan[1]; Linden Lalley-Chareczko[2]; Ganesh Moorthy[3]; S. Caitlin Conyngham[2]; Elizabeth Ketner[1]; Luis J. Montaner[4]; Pablo Tebas[1]

[1]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, US; [2]Philadelphia FIGHT, Philadelphia, PA, US; [3]The Children's Hospital of Philadelphia, Philadelphia, PA, US; [4]Wistar Institute, Philadelphia, PA, US

976 Comparison of Adherence Measures in a Clinical Trial of Preexposure Prophylaxis

Davis C. Muganzi[1]; Jessica Haberer[2]; Yap Boum[1]; Nicholas Musinguzi[1]; Allan Ronald[4]; Connie Celum[3]; Jared Baeten[3]; David R. Bangsberg[4]

[1]Mbarara University of Science and Technology, Kampala, Uganda; [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [3]University of Washington, Seattle, WA, US; [4]University of Manitoba, Winnipeg, Canada

977 Self-Reported Recent PrEP Use Has Strong Relation to Drug Detection in iPrEx OLE

Rivet Amico[1]; Vanessa McMahan[2]; Megha Mehrotra[2]; Peter L. Anderson[2]; Juan Guanira[2]; Valdilea Veloso[2]; Robert M. Grant[2]
the iPrEx study team

[1]University of Michigan, Ann Arbor, MI, US; [2]Gladstone Institute, San Fransicso, CA, US

978LB HPTN 067/ADAPT Cape Town: A Comparison of Daily and Nondaily PrEP Dosing in African Women

Linda-Gail Bekker[1]; james Hughes[2]; Rivet Amico[4]; Surita Roux[3]; Craig Hendrix[5]; Peter L. Anderson[6]; Bonnie Dye[7]; Vanessa Elharrar[8]; Michael J. Stirratt[9]; Robert Grant[10]

[1]Dept of Medicine and Institute of Infectious Disease and Molecular Medicine, Cape Town, South Africa; [2]HIV Prevention Trials Network, Seattle, WA, US; [3]The Desmond Tutu HIV Centre, Cape Town, South Africa; [4]University of Michigan, Ann Arbor, MI, US; [5]Johns Hopkins University, Baltimore, MD, US; [6]University of Colorado, Aurora, CO, US; [7]FHI360, Durham, NC, US; [8]PSP/DAIDS/NIAID/NIH, Bethesda, MD, US; [9]Center for Mental Health Research on AIDS, Bethesda, MD, US; [10]University of California, San Francisco, CA, US

979 Correlates of Early Adherence in VOICE PrEP Trial Differ Between Oral and Vaginal Products

Ariane van der Straten[1]; Elizabeth R. Brown[2]; James Dai[2]; Craig Hendrix[3]; Karen Liu[2]; Cynthia Grossman[4]; Z M. Chirenje[5]; Jeanne Marrazzo[6]

[1]RTI, San Francisco, CA, US; [2]Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US; [3]Johns Hopkins University School of Medicine, Baltimore, MD, US; [4]National Institute of Mental Health (NIMH), Bethesda, MD, US; [5]University of Zimbabwe–University of California San Francisco Research Collaboration, Harare, Zimbabwe; [6]University of Washington, Seattle, WA, US

980 Intimate Partner Violence Is Associated With Low PrEP Adherence in African Women

Sarah T. Roberts[1]; Connie Celum[1]; Nelly Mugo[3]; Jessica Haberer[2]; Craig R. Cohen[4]; Elizabeth Irungu[5]; James N. Kiarie[6]; Edwin Were[7]; Jared Baeten[1]
On behalf of the Partners PrEP Study Team

[1]University of Washington, Seattle, WA, US; [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [3]Kenya Medical Research Institute, Nairobi, Kenya; [4]University of California San Francisco, San Francisco, CA, US; [5]Kenyatta National Hospital, Nairobi, Kenya; [6]University of Nairobi, Nairobi, Kenya; [7]Moi University, Eldoret, Kenya

WEDNESDAY, FEBRUARY 25, 2015

Session P-V5 Poster Session — Poster Hall

2:30 pm – 4:00 pm

PrEP: Evaluating Potential Harm

981 Reversibility of Kidney Function Decline in HIV-1–Uninfected Men and Women Using Preexposure Prophylaxis

Kenneth K. Mugwanya[1]; Christina Wyatt[2]; Connie Celum[1]; Deborah Donnell[3]; Nelly Mugo[4]; James N. Kiarie[5]; Allan Ronald[6]; Jared Baeten[1]
On behalf of the Partners PrEP Study Team

[1]University of Washington, Seattle, WA, US; [2]Mount Sinai School of Medicine, New York, NY, US; [3]Fred Hutchinson Cancer Research Center, Seattle, WA, US; [4]Kenya Medical Research Institute, Nairobi, Kenya; [5]University of Nairobi, Nairobi, Kenya; [6]University of Manitoba, Winnipeg, Canada

982 Minor Drug-Resistant Variants Infrequently Detected in Seroconverters From MTN 003 (VOICE)

Constantinos Panousis[1]; Elias K. Halvas[1]; Cliff Kelly[2]; Jeanne Marrazzo[3]; Z M. Chirenje[4]; John W. Mellors[1]; **Urvi M. Parikh**[1]
On behalf of the MTN 003 Protocol Team

[1]University of Pittsburgh, Pittsburgh, PA, US; [2]Fred Hutchinson Cancer Research Center, Seattle, WA, US; [3]University of Washington, Seattle, WA, US; [4]UZ-UCSF Collaborative Research Programme, Harare, Zimbabwe

983 PrEP-Selected Drug Resistance Fades by Six Months Following Drug Cessation

Julie F. Weis[1]; Jared Baeten[2]; Ruth Kanthula[3]; Connor McCoy[1]; Lisa Frenkel[2]; Nelly Mugo[2]; Frederick Matsen[1]; Julie M. Overbaugh[1]; Connie Celum[2]; Dara A. Lehman[1]

[1]Fred Hutchinson Cancer Research Center, Seattle, WA, US; [2]University of Washington, Seattle, WA, US; [3]Seattle Children's Research Institute, Seattle, WA, US; [4]Fred Hutchinson Cancer Research Center, Seattle, WA, US

984 Randomized Controlled Trial on ART Outcomes in Tenofovir Gel Trial Seroconvertors

Anushka Naidoo; Nivashnee Naicker; Lise Werner; Nigel Garrett; Sarah Dlamini; Villeshni Asari; Nelisile Majola; Cheryl Baxter; Quarraisha Abdool Karim; Salim S. Abdool Karim

Center for the AIDS Program of Research in South Africa, Durban, South Africa

985 Frequent Dapivirine Cross-Resistance of HIV from 1st-line ART Failures in S. Africa

Kerri J. Penrose[1]; Kristen A. Hamanishi[1]; Kelley C. Gordon[1]; Raquel V. Viana[2]; Carole L. Wallis[3]; John W. Mellors[1]; Urvi M. Parikh[1]

[1]University of Pittsburgh, Pittsburgh, PA, US; [2]Lancet Laboratories, Johannesburg, South Africa; [3]Lancet Laboratories/BARC-SA, Johannesburg, South Africa

986 Effect of TDF Monotherapy PrEP on Immune Function in Seroconverting Individuals

Marcel E. Curlin[1]; Michael T. Martin[1]; Punneeporn Wasinrapee[2]; Wanna Leelawiwat[2]; Boonyos Raengsakulrach[2]; Janet McNicholl[1]; Pravan Suntharasamai[3]; Udomsak Sangkum[3]; Suphak Vanichseni[3]; Kachit Choopanya[3]

[1]US Centers for Disease Control and Prevention (CDC), Apo, US; [2]Thailand Ministry of Public Health-Centers for Disease Control and Prevention Collaboration, Nothaburi, Thailand; [3]Bangkok Tenofovir Study Group, Bangkok, Thailand

987 The Impact of Preexposure Prophylaxis on Antibody Maturation in HIV-Infected Women

Oliver B. Laeyendecker[1]; Andrew D. Redd[1]; Martha Nason[3]; Andrew Longosz[1]; Quarraisha Abdool Karim[2]; Vivek Naranbhai[2]; Nigel Garrett[2]; Salim S. Abdool Karim[2]; Thomas C. Quinn[1]

[1]National Institute of Allergy and Infectious Diseases, Baltimore, MD, US; [2]CAPRISA, University of KwaZulu-Natal, Congella, South Africa; [3]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD, US

988 Medication Sharing Among African HIV Serodiscordant Couples Enrolled in a PrEP Trial

Kerry A. Thomson[1]; Jessica Haberer[4]; Connie Celum[1]; Andrew Mujugira[1]; Patrick Ndase[1]; Craig Hendrix[2]; Mark A. Marzinke[2]; Allan Ronald[3]; David Bangsberg[4]; Jared Baeten[1]
On behalf of the Partners PrEP Study Team

[1]University of Washington, Seattle, MA, US; [2]Johns Hopkins University, Baltimore, MD, US; [3]University of Manitoba, Winnipeg, Canada; [4]Massachusetts General Hospital, Boston, MA, US

THURSDAY, FEBRUARY 26, 2015

Session P-V6 Poster Session — Poster Hall

2:30 pm – 4:00 pm

HIV Prevention, Miscellaneous

989 HIV-1 Transmission Risk Persists During the First 6 Months of Antiretroviral Therapy

Andrew Mujugira[1]; Katherine Thomas[1]; Connie Celum[1]; Deborah Donnell[2]; Carey Farquhar[1]; Elizabeth Bukusi[3]; Jared Baeten[1]
On behalf of the Partners PrEP Study Team

[1]University of Washington, Seattle, WA, US; [2]Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US; [3]Kenya Medical Research Institute, Nairobi, Kenya

990 Long-Term ART Outcomes in Botswana Encouraging Treatment as Prevention Approach

Hermann Bussmann[4]; William C. Wester[1]; Ernest Fetogang[2]; Tony Chebani[2]; Sikhulile Moyo[3]; Naledi M. Mlaudzi[2]; Erik V. Widenfelt[3]; Joseph Makhema[3]; Max Essex[4]; Richard Marlink[4]

[1]Vanderbilt University School of Medicine, Nahville, TN, US; [2]Ministry of Health, Gaborone, Botswana; [3]Botswana Harvard AIDS Institute Partnership for HIV Research and Education, Gaborone, Botswana; [4]Harvard School of Public Health, Boston, MA, US

991LB Use of Population Viral Load to Predict HIV-Incidence in a Hyperendemic Population in Rural KwaZulu-Natal, South Africa

Frank Tanser[3]; Tulio de Oliveira[3]; Till Barnighausen[2]; Deenan Pillay[1]

[1]University College London, London, United Kingdom; [2]Harvard School of Public Health, Boston, MA, US; [3]University of KwaZulu-Natal, Mtubatuba, South Africa

992LB Phase 1 Safety & PK Trial of Polyurethane Tenofovir Disoproxil Fumarate Vaginal Ring

Marla J. Keller[1]; Pedro Mesquita[1]; Mark A. Marzinke[2]; Ryan Teller[3]; Bruce Frank[4]; Mark Mitchnick[4]; Peter L. Anderson[5]; Craig Hendrix[2]; Patrick F. Kiser[3]; Betsy Herold[1]

[1]Albert Einstein College of Medicine, Bronx, NY, US; [2]Johns Hopkins University School of Medicine, Baltimore, MD, US; [3]Northwestern University, Evanston, IL, US; [4]Particle Sciences, Inc, Bethlehem, PA, US; [5]University of Colorado, Aurora, CO, US

993 Investigating the Pharmacokinetics of Rectal 1% Tenofovir Gel in Rhesus Macaques

Charles W. Dobard[1]; Andrew Taylor[1]; Chuong Dinh[1]; Chou-Pong Pau[1]; Ian McGowan[2]; Lisa Rohan[2]; Walid Heneine[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, USA, Atlanta, GA, US; [2]University of Pittsburgh Magee-Womens Research Institute, Pittsburgh, PA, US

994 CHARM-01, a Phase 1 Rectal Safety, Acceptability, PK/PD Study of 3 Tenofovir Gels

Ian McGowan[1]; Kathy Duffill[2]; Charlene Dezzutti[1]; Nicola Richardson-Harman[3]; Mark A. Marzinke[4]; Ross D. Cranston[1]; Lisa Rohan[1]; Craig W. Hendrix[4]; Julie Elliott[5]; Peter Anton[5]

[1]University of Pittsburgh, Pittsburgh, PA, US; [2]Magee-Womens Research Institute, Pittsburgh, PA, US; [3]Alpha StatConsult LLC, Damascus, MD, US; [4]Johns Hopkins University School of Medicine, Baltimore, MD, US; [5]David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA, US

995 Female Condom Functionality in the Presence of a Vaginal Ring

Annalene M. Nel[1]; Mildie Leuvennink[1]; Neliette Van Niekerk[1]; Terri Walsh[2]; Ron Frezieres[2]

[1]International Partnership for Microbicides, Paarl, South Africa; [2]California Family Health Council Inc, Los Angeles, CA, US

TUESDAY, FEBRUARY 24, 2015

Session P-W1 Poster Session — Poster Hall

2:30 pm – 4:00 pm

HIV Testing and the Continuum of Care in the Industrialized World

996 Continuous Retention Predicts Viral Suppression Across the US and Canada

Peter F. Rebeiro[1]; Baligh R. Yehia[2]; Kelly Gebo[3]; Bryan Lau[3]; Kenneth H. Mayer[4]; Michael A. Horberg[5]; Mari Kitahata[6]; John Gill[7]; Timothy Sterling[1]; Stephen J. Gange[3]
North American AIDS Cohort Collaboration on Research and Design (NA-ACCORD)

[1]Vanderbilt University, Nashville, TN, US; [2]University of Pennsylvania, Philadelphia, PA, US; [3]Johns Hopkins University, Baltimore, MD, US; [4]Harvard University, Boston, MA, US; [5]Mid-Atlantic Permanente Research Institute, Kaiser Permanente Mid-Atlantic States, Rockville, MD, US; [6]University of Washington, Seattle, WA, US; [7]University of Calgary, Alberta Health Services, Calgary, Canada

997 Disparities in HIV Viral-Load Suppression Among MSM, the HIV Outpatient Study, 2013

Kate Buchacz[1]; Carl Armon[2]; Ellen Tedaldi[3]; Frank J. Palella[4]; Richard Novak[5]; Doug Ward[6]; Benjamin Young[7]; Rachel Debes[2]; Marcus Durham[1]; John T. Brooks[1]

[1]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US; [2]Cerner Corporation, Vienna, VA, US; [3]Temple University School of Medicine, Philadelphia, PA, US; [4]Northwestern University, Chicago, IL, US; [5]University of Illinois at Chicago, Chicago, IL, US; [6]Dupont Circle Physicians Group, Washington, DC, US; [7]International Association of Providers in AIDS Care, Washington, DC, US

998 Early Linkage to HIV Care and Antiretroviral Therapy Use Among People Who Inject Drugs: 20 US Cities, 2009 and 2012

Brooke Hoots; Teresa Finlayson; Dita Broz; Gabriela Paz-Bailey

US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US

999 Late HIV Diagnosis in Metropolitan Areas of the United States and Puerto Rico

H. Irene Hall[1]; Tian Tang[2]; Lorena Espinoza[1]

[1]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US; [2]ICF International, Atlanta, GA, US

1000 HIV Care During the Last Year of Life

H. Irene Hall[1]; Lorena Espinoza[1]; Shericka Harris[2]; Jing Shi[2]

[1]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US; [2]ICF International, Atlanta, GA, US

1001 Reductions in the Time From HIV Infection to ART Initiation in New York City

Sarah L. Braunstein[1]; McKaylee Robertson[2]; Julie Myers[1]; Bisrat Abraham[3]; Denis Nash[4]

[1]New York City Department of Health and Mental Hygiene, Queens, NY, US; [2]City University of New York, New York, NY, US; [3]Weill Cornell Medical College, New York, NY, US; [4]City University of New York School of Public Health, New York, NY, US

1002 Return to HIV-Related Medical Care After a Hiatus of ≥1 Year, New York State, 2013

Carol-Ann Swain[4]; Daniel Gordon[4]; Jessica L. Simpson[3]; Bridget J. Anderson[4]; Bruce D. Agins[1]; Lou C. Smith[2]

[1]Office of the Medical Director, New York State Department of Health, New York, NY, US; [2]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US; [3]Division of Epidemiology, Evaluation and Research, New York State Department of Health, Albany, NY, US; [4]New York State Department of Health, Albany, NY, US

1003 Care-Cascade Status of Partners of Persons With New HIV Infections in North Carolina

Anna B. Cope[1]; Lisa Hightow-Weidman[1]; JoAnn D. Kuruc[1]; Jenni Marmorino[1]; Steve Beagle[1]; Philip J. Peters[2]; Cynthia L. Gay[1]

[1]University of North Carolina, Chapel Hill, NC, US; [2]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US

1004 The Role of HIV Status Disclosure in Retention in Care and Viral-Load Suppression

Latesha E. Elopre; Andrew Westfall; Michael J. Mugavero; Anne Zinski; Greer Burkholder; Edward Hook; Nicholas Van Wagoner

University of Alabama at Birmingham, Birmingham, AL, US

1005 Alcohol and Substance Use and Timing of Presentation to HIV Care Across the United States

Jesse Abbott Klafter[1]; Daniel R. Drozd[3]; Michael J. Mugavero[2]; Katerina Christopoulos[4]; Christopher W. Mathews[7]; Joseph J. Eron[8]; Kenneth H. Mayer[6]; Matthew Mimiaga[5]; Mari Kitahata[3]; Heidi M. Crane[3]
Center for AIDS Research Network of Integrated Clinical Systems (CNICS)

[1]University of Washington, Seattle, WA, US; [2]University of Alabama at Birmingham, Birmingham, AL, US; [3]University of Washington, Seattle, WA, US; [4]University of California San Francisco, San Francisco, CA, US; [5]Harvard Medical School, Boston, MA, US; [6]Fenway Health, Boston, MA, US; [7]University of California San Diego (UCSD), San Diego, CA, US; [8]University of North Carolina, Chapel Hill, NC, US

1006 Marijuana Use and Its Nuanced Relationship With HIV Treatment Continuum Metrics

John A. Schneider[1]; Ethan Morgan[1]; Stuart Michaels[2]; Britt Skaathun[1]; Lindsay Young[1]; Robert W. Coombs[3]; Phil Schumm[1]; Dexter Voisin[1]; Sam Friedman[4]
UConnect Study Team

[1]University of Chicago, Chicago, IL, US; [2]NORC, Chicago, IL, US; [3]University of Washington, Seattle, WA, US; [4]National Development Research Institute, New York, NY, US

1007 "Test-and-Treat" in the Netherlands

Ard van Sighem[1]; Luuk Gras[1]; Eline Op de Coul[2]; Daniela Bezemer[1]; Michiel van Agtmael[3]; Godelieve de Bree[4]; Peter Reiss[1]
On behalf of the ATHENA National Observational HIV Cohort

[1]Stichting HIV Monitoring, Amsterdam, Netherlands; [2]National Institute for Public Health and the Environment, Bilthoven, Netherlands; [3]VU University Medical Centre, Amsterdam, Netherlands; [4]Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands

1008 Estimates of HIV Prevalence, Proportion of Diagnosed Patients and Quality of Treatment in Switzerland

Philipp Kohler[2]; Axel J. Schmidt[3]; Bruno Ledergerber[2]; **Pietro L. Vernazza**[1]

[1]Cantonal Hospital St. Gallen, St. Gallen, Switzerland; [2]Universitätsspital Zürich, Zurich, Switzerland; [3]Federal Office of Public Health, Bern, Switzerland

1009 Medical Care Interruptions in HIV-infected Patients: Characteristics and Consequences

Lise Cuzin[1]; Pierre Dellamonica[2]; Yazdan Yazdanpanah[7]; Sabelline Bouchez[3]; David Rey[6]; Bruno Hoen[5]; André Cabié[4]

[1]Toulouse University Hospital, Toulouse, France; [2]University Hospital, Nice, Nice, France; [3]University Hospital, Nantes, France; [4]University Hospital, Fort de France, France; [5]University Hospital, Pointe à Pitre, France; [6]University Hospital, Strasbourg, France; [7]Hôpital Bichat-Claude Bernard, APHM, Paris, France

1010 Blood Donor Test-Seeking Motivation and Prior HIV Testing Experiences in São Paulo

Hong-Ha M. Truong[1]; Paula Blatyta[2]; Sandra Montebello[2]; Sandra Esposti[2]; Fatima Hangai[2]; Nanci Salles[2]; Alfredo Mendrone[2]; Ester C. Sabino[3]; Willi McFarland[4]; Thelma T. Gonçalez[5]

[1]University of California San Francisco, San Francisco, CA, US; [2]Fundação Pró-Sangue/ Hemocentro de São Paulo, São Paulo, Brazil; [3]University of São Paulo, São Paulo, Brazil; [4]San Francisco Department of Public Health, San Francisco, CA, US; [5]Blood Systems Research Institute/University of California San Francisco, San Francisco, CA, US

Session P-W2 Poster Session — Poster Hall

2:30 pm – 4:00 pm

HIV Testing and the Continuum of Care in the Developing World

1011 Treatment Interruptions in ART Programmes in Resource-Limited Settings: 2003 to 2013

Gail B. Cross[1]; Tim Spelman[2]; Daniel P. O'Brien[4]; Nathan Ford[3]; Jane Greig[4]; James H. McMahon[1]

[1]Monash University/Alfred Hospital, Prahan, Australia; [2]Burnet Institute, Melbourne, Australia; [3]World Health Organization (WHO), Geneva, Switzerland; [4]Médecins Sans Frontières, London, United Kingdom

1012 Time to ART Qualification and Retention Among Patients With Early HIV in Haiti

Rita T. Dadaille[1]; Serena P. Koenig[1]; Kelley Henessey[2]; Ellie Cooper[2]; Pierre Cremieux[2]; William J. Pape[1]
Analysis Group; Les Centres GHESKIO IT Team

[1]Gheskio Centers, Port au Prince, Haiti; [2]Analysis Group, Boston, MA, US

1013 Awareness of HIV Diagnosis in the Swaziland HIV Incidence Measurement Survey

Tanya M. Ellman[1]; Ruth Emerson[4]; Deborah Donnell[4]; Neena M. Philip[1]; Rejoice Nkambule[2]; Naomi Bock[3]; Peter Ehrenkranz[5]; George Bicego[3]; Jessica E. Justman[1]

[1]ICAP at Columbia University, New York, NY, US; [2]Ministry of Health, Mbabane, Swaziland; [3]US Centers for Disease Control and Prevention, Atlanta, GA, US; [4]Fred Hutchinson Cancer Research Center, Seattle, WA, US; [5]Centers for Disease Control and Prevention, Mbabane, Swaziland

1014 Who Is at Risk of Being Untested and Unaware of HIV-Positive Status in KwaZulu-Natal?

Helena Huerga[1]; Gilles Van Cutsem[2]; Jihane Ben Farhat[1]; Malika Bouhenia[1]; Matthew Reid[2]; David Maman[1]; Jean-François Etard[1]; Thomas Ellman[2]

[1]Epicentre, Paris, France; [2]Médecins Sans Frontières, Cape Town, South Africa

1015 Impact of Unplanned Care Interruption on Immune Recovery After ART Initiation in Nigeria

Aimalohi A. Ahonkhai[1]; Juliet Adeola[2]; Bolanle Banigbe[2]; Ifeyinwa Onwuatuelo[2]; Ingrid V. Bassett[1]; Elena Losina[3]; Kenneth A. Freedberg[1]; Prosper Okonkwo[2]; Susan Regan[1]

[1]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [2]AIDS Prevention Initiative Nigeria, Jabi District, Nigeria; [3]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, US

1016 Linkage to HIV Care Among Men Who Have Sex With Men and Drug Users in India: Getting to 90

Sunil S. Solomon[1]; Allison M. McFall[2]; Aylur K. Srikrishnan[3]; Gregory M. Lucas[1]; Canjeeveram K. Vasudevan[3]; David D. Celentano[2]; Muniratnam S. Kumar[3]; Suniti Solomon[3]; Shruti H. Mehta[2]

[1]Johns Hopkins University School of Medicine, Baltimore, MD, US; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [3]YR Gaitonde Centre for AIDS Research and Education, Chennai, India

WEDNESDAY, FEBRUARY 25, 2015

Session P-W3 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Risk Factors for Transmission in MSM

1017 Sex Pro: A Personalized HIV Risk Assessment Tool for Men Who Have Sex With Men

Hyman Scott[1]; Eric Vittinghoff[2]; Risha Irving[3]; Albert Liu[1]; Sheldon D. Fields[5]; Manya Magnus[6]; Darrell P. Wheeler[7]; Kenneth H. Mayer[4]; Beryl A. Koblin[8]; Susan P. Buchbinder[1]

[1]San Francisco Department of Public Health, San Francisco, CA, US; [2]University of California San Francisco, San Francisco, CA, US; [3]Johns Hopkins University School of Medicine, Baltimore, MD, US; [4]Fenway Health, Boston, MA, US; [5]Florida International University, Miami, FL, US; [6]George Washington University, Washington, DC, US; [7]Loyola University Chicago, Chicago, IL, US; [8]New York Blood Center, New York, NY, US

1018 Unreported Sexual Risk Behavior Among MSM Newly Diagnosed With HIV Infection

Hsiu Wu[1]; Lisa B. Hightow-Weidman[2]; Cindy L. Gay[2]; Tonyka Jackson[3]; Emily Pike[2]; Jenni Marmorino[2]; Steve Beagle[2]; Laura Hall[3]; Philip J. Peters[1]

[1]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US; [2]University of North Carolina, Chapel Hill, NC, US; [3]ICF International, Atlanta, GA, US

1019LB HIV Transmission in Male Serodiscordant Couples in Australia, Thailand and Brazil

Andrew E. Grulich[1]; Benjamin R. Bavinton[1]; Fengyi Jin[1]; Garrett Prestage[1]; Iryna B. Zablotska[1]; Beatriz Grinsztejn[2]; Nittaya Phanuphak[3]; Richard Moore[4]; Kersten K. Koelsch[1]
On behalf of the Opposites Attract Study Group

[1]University of New South Wales, Sydney, Australia; [2]Instituto de Pesquisa Clínica Evandro Chagas, Rio de Janiero, Brazil; [3]Thai Red Cross AIDS Research Centre, Bangkok, Thailand; [4]Northside Clinic, Melbourne, Australia

1020 Seminal Shedding of CMV and HIV Transmission Among Men Who Have Sex With Men

Sara Gianella Weibel[1]; Konrad Scheffler[1]; Sanjay Mehta[1]; Susan J. Little[1]; Lorri Freitas[2]; Sheldon R. Morris[1]; David M. Smith[1]

[1]University of California San Diego, La Jolla, CA, US; [2]County of San Diego Public Health Services, San Diego, CA, US

1021 Risk Factors for Acute and Early HIV Infection Among MSM in San Diego, 2008–2014

Martin Hoenigl; Christy M. Anderson; Sanjay Mehta; Nella L. Green; Davey M. Smith; Susan Little

University of California San Diego, San Diego, CA, US

1022 Influence of Voluntary Repeat HIV Testing on Sexual Risk Behavior Among MSM

Martin Hoenigl; Davey M. Smith; Christy M. Anderson; Nella L. Green; Sanjay Mehta; Susan J. Little

University of California San Diego, San Diego, CA, US

1023 HIV-Positive MSM With Unsuppressed Viral Load Are More Likely to Engage in Risky Sex: Vancouver, Canada

David Moore[1]; Zishan Cui[1]; Nathan J. Lachowsky[1]; Henry F. Raymond[2]; Eric Roth[3]; Asheligh Rich[1]; Paul Sereda[1]; Julio Montaner[1]; Mark Gilbert[4]; Robert Hogg[1]

[1]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada; [2]San Francisco Department of Public Health, San Francisco, CA, US; [3]University of Victoria, Victoria, Canada; [4]BC Centre for Disease Control, Vancouver, Canada

1024 Substance Use, Mental Health, and HIV Risk Behavior Among MSM in Vancouver, Canada

Nathan J. Lachowsky[1]; Zishan Cui[2]; Asheligh Rich[2]; Paul Sereda[2]; Thomas L. Patterson[3]; Trevor Corneil[1]; Mark Gilbert[4]; Eric Roth[5]; Robert Hogg[6]; David Moore[1]

[1]University of British Columbia, Vancouver, Canada; [2]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada; [3]University of California San Diego, San Diego, CA, US; [4]Ontario HIV Treatment Network, Toronto, Canada; [5]University of Victoria, Victoria, Canada; [6]Simon Fraser University, Burnaby, Canada

1025 Electronic and Online Innovations in Respondent-Driven Sampling Methodology

Nathan J. Lachowsky[1]; Allan Lal[2]; Zishan Cui[2]; Asheligh Rich[2]; Paul Sereda[2]; Henry Fisher Raymond[3]; Jamie I. Forrest[1]; Eric Roth[4]; Robert Hogg[2]; David Moore[1]

[1]University of British Columbia, Vancouver, Canada; [2]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada; [3]University of California San Francisco, San Francisco, CA, US; [4]University of Victoria, Victoria, Canada

1026 Incident Symptomatic Gonorrhea Infection Among Men Who Have Sex With Men, Thailand

Marcel E. Curlin[1]; Sarika Pattanasin[1]; Pikunchai Luechai[1]; Anuwat Sriporn[1]; Jaray Tongtoyai[1]; Eileen F. Dunne[1]; Wichuda Sukwicha[1]; Oranuch Kongpechsatit[1]; Pachara Sirivongrangson[2]; Timothy Holtz[1]

[1]US Centers for Disease Control and Prevention (CDC), Apo, US; [2]Thai Ministry of Public Health, Nonthaburi, Thailand

Session P-W4 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Transmission Through Needles and Heterosexual Contact

1027 Occupationally Acquired HIV Infection by Healthcare Personnel–United States, 1985-2013

M Patricia Joyce; David Kuhar; John T. Brooks

US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US

1028 Analyzing Trends in HIV Risks for Injection Drug Users by Respondent-Driven Sampling

Kathleen A. Brady; Tanner B. Nassau; Jennifer Shinefeld; Catherine Mezzacappa

Philadelphia Department of Public Health, Philadelphia, PA, US

1029 Sexual Transmission of HIV and Possible Underreporting of Drug Use in Kazakhstan

Anna Deryabina; Padmaja Patnaik; Charon Gwynn; Wafaa M. El-Sadr

ICAP at Columbia University, Almaty, Kazakhstan

1030 Can We Trust Self-Reported Condom Use? Association Between Reporting Bias and STIs

Hongjie Liu

University of Maryland, College Park, College Park, MD, US

1031 Prevalence and Correlates of Exchange Sex Among Low-Income Heterosexual Women in 21 US Cities

Catlainn Sionean; Rashunda Lewis; Lina M. Nerlander; Gabriela Paz-Bailey
On behalf of the NHBS Study Group

US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US

1032 HIV and STIs Among Transgendered Populations: Four Country Survey From Central America

David Ham[1]; Sanny Y. Northbrook[2]; Sonia Morales-Miranda[3]; Maria Elena Guardado[4]; Mary Kamb[1]

[1]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US; [2]CDC Central America Region, Guatemala City, Guatemala; [3]HIV Unit of Center for Health Studies, Del Valle University of Guatemala, Guatemala City, Guatemala; [4]TEPHINET/ The Taskforce for Global Health Inc., Guatemala City, Guatemala

1033 Incidence of Curable Sexually Transmitted Infections Among South African Women Recently Infected With HIV

Jennifer E. Balkus[1]; Marla E. Husnik[1]; Thesla Palanee-Phillips[2]; Ravindre Panchia[3]; Ishana Harkoo[4]; Arendevi Pather[5]; Vaneshree Govender[5]; Marthinette Taljaard[6]; Pamina Gorbach[7]; Sharon Riddler[8]

[1]Fred Hutchinson Cancer Research Center, Seattle, WA, US; [2]University of the Witwatersrand, Johannesburg, South Africa; [3]Chris Hani Baragwanath Academic Hospital, Johannesburg, South Africa; [4]CAPRISA/University of KwaZulu-Natal, Durban, South Africa; [5]Medical Research Council, Durban, South Africa; [6]The Aurum Institute, Klerksdorp, South Africa; [7]University of California Los Angeles, Los Angeles, CA, US; [8]University of Pittsburgh, Pittsburgh, PA, US

1034 Population Mobility, Sexual Behavior and Risk of HIV Infection in Sub-Saharan Africa

Laurence Palk; Sally Blower
On behalf of the Center for Biomedical Modeling

David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA, US

1035 HIV Transmission Linkage Among Seroconverting Partners in HIV-Discordant Relationships in Kenya

Bhavna H. Chohan[1]; Brandon L. Guthrie[2]; Brian Khasimwa[4]; Stephanie Rainwater[3]; Barbara Lohman-Payne[2]; Rose Bosire[2]; Romel D. Mackelprang[2]; Julie M. Overbaugh[3]; Carey Farquhar[2]

[1]Kenya Medical Research Institute, Nairobi, Kenya; [2]University of Washington, Seattle, WA, US; [3]Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US; [4]University of Nairobi, Nairobi, Kenya

1036 Rising School Enrollment & Declining HIV Risk, 15-19y, Rakai, Uganda, 1994-2013

John Santelli[1]; Sanyukta Mathur[1]; Xiao Yu Song[2]; Tzu-Jung Huang[2]; Ying Wei[2]; Tom Lutalo[3]; Fred Nalugoda[3]; Ronald H. Gray[4]; David Serwadda[3]

[1]New York–Presbyterian University Hospital of Columbia and Cornell, New York City, NY, US; [2]Columbia University–Mailman School of Public Health, New York, NY, US; [3]Rakai Health Sciences Program, Entebbe, Uganda; [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US

1037 Alcohol Use and HIV Risk Factors: Results From the 2011 Uganda AIDS Indicator Survey

George Aluzimbi

CDC Center for Global Health, Division of Global AIDS/HIV, Kampala, Uganda

1038 Population Attributable Fraction of HIV Due to Alcohol in Fishing Communities, Uganda

Noah Kiwanuka[5]; Ismail Ssekandi[2]; Ali Ssetaala[2]; Annet Nalutaaya[2]; Juliet Mpendo[2]; Paul K. Kitandwe[2]; Jan D. Bont[3]; Pontiano Kaleebu[4]; Nelson K. Sewankambo[5]

[1]Makerere University College of Health Sciences, Kampala, Uganda; [2]UVRI-IAVI HIV Vaccine Program, Entebbe, Uganda; [3]International AIDS Vaccine Initiative, New York, NY, US; [4]MRC/UVRI Uganda Research Unit on AIDS, Entebbe, Uganda; [5]Makerere University College of Health Sciences, Kampala, Uganda

1039 Risky Sexual Behavior and HIV Infection Among Fisher Folk: Lake Kyoga Region, Uganda

Rose Apondi[1]; Rhoda Wanyenze[2]; Herbert S. Kiyingi[2]; Abdu-Maliki Muyinda[2]; Elizabeth Meassick[1]; Joy Kusiima[2]; David Serwadda[2]

[1]CDC Center for Global Health, Division of Global AIDS/HIV, Kampala, Uganda; [2]Makerere University School of Public Health, Kampala, Uganda

THURSDAY, FEBRUARY 26, 2015

Session P-W5 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Incidence and Prevalence of HIV Infection, Including Acute HIV

1040 Increases in HIV Diagnoses Among MSM in Metropolitan Statistical Areas, United States, 2003–2012

Lorena Espinoza; H. Irene Hall; Tian Tang; Anna Satcher Johnson; Amy Lansky

US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US

1041 Disparities in HIV by Race and Age Among Men Who Have Sex With Men, 20 US Cities

Cyprian Wejnert; Kristen Hess; Chuck E. Rose; **Alexandra B. Balaji**; Justin C. Smith; Gabriela Paz-Bailey
On behalf of the NHBS Study Group

US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US

1042 HIV Incidence Estimates, Introducing the Limiting Antigen Avidity EIA to Existing HIV Surveillance in Kiev City, Ukraine: 2013–2014

Ruth Simmons[1]; Ruslan Malyuta[2]; Nelli Chentsova[3]; Iryna Karnets[3]; Gary Murphy[4]; Antonia Medoeva[3]; Yuri Kruglov[5]; Alexander Yurchenko[3]; Kholoud Porter[1]; Andrew Copas[1]

[1]Medical Research Council at University College London, London, United Kingdom; [2]Perinatal Prevention of AIDS Initiative, Odessa, Ukraine; [3]Kyiv City AIDS Centre, Kyiv City, Ukraine; [4]Public Health England, London, United Kingdom; [5]Institute of Epidemiology, Kyiv, Ukraine

1043 Detection of Acute HIV Infection, US National HIV Surveillance System, 2008–2012

Laurie Linley; Qian An; Kristen Mahle Gray; Alexandra Oster; Angela L. Hernandez

US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US

1044 Differences in Acute Retroviral Syndrome by HIV-1 Subtype in a Multicentre Cohort Study in Africa

Eduard J. Sanders[1]; Kimberly A. Powers[2]; Etienne Karita[3]; Anatoli Kamali[4]; William Kilembe[5]; Susan Allen[6]; Eric Hunter[6]; Omu Anzala[7]; Pat Fast[8]; Matthew Price[8]

[1]KEMRI-Wellcome Trust Research Programme, Kilifi, Kenya; [2]University of North Carolina, Chapel Hill, NC, US; [3]Project San Francisco, Kigali, Rwanda; [4]Medical Research Council/ Uganda Virus Research Institute, Entebbe, Uganda; [5]Zambia Emory Research Project, Lusaka, Zambia; [6]Emory University, Atlanta, GA, US; [7]Kenya AIDS Vaccine Initiative, Nairobi, Kenya; [8]International AIDS Vaccine Initiative,, New York, NY, US

1045 Using GPS Data to Construct a Spatial Map of the HIV Epidemic in Malawi

Danielle E. Robbins; Brian J. Coburn; Sally Blower

David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA, US

1046 HIV Incidence in Rural Malawi During Widespread Antiretroviral Treatment Availability

Alison Price[1]; Menard Chihana[2]; Ndoliwe Kayuni[2]; Amelia C. Crampin[1]; Milly Marston[1]; Basia Zaba[1]; Estelle McLean[1]; Olivier Koole[1]; Moffat Nyirenda[1]

[1]London School of Hygiene and Tropical Medicine, Chilumba, Malawi; [2]Karonga Prevention Study, Chilumba, Malawi

1047 HIV-1 Incidence Among Adult STI Clinic Patients in Blantyre, Malawi

Fatima Zulu[1]; Isaac Singini[1]; Newton I. Kumwenda[1]; Johnstone Kumwenda[1]; Sufia Dadabhai[2]

[1]Johns Hopkins University Research Project, Blantyre, Malawi; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US

Session P-W6 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Disease Progression, Morbidity, and Mortality

1048 CD4 Cell Dynamics in HIV-1 Infection Before and After ART: Overview and Determinants

Anne Cori[1]; Mike Pickles[1]; Ard van Sighem[2]; Luuk Gras[2]; Daniela Bezemer[2]; Peter Reiss[2]; Christophe Fraser[1]
On behalf of the ATHENA Observational Cohort

[1]Imperial College London, London, United Kingdom; [2]HIV Monitoring Foundation, Academic Medical Centre, University of Amsterdam, Amsterdam, Netherlands

1049 IL-6 Partially Mediates the Effect of HIV Status on Survival

Kaku So-Armah[1]; Amy Justice[2]; David Rimland[3]; Maria Rodriguez-Barradas[4]; Adeel A. Butt[5]; David Leaf[6]; Russell Tracy[7]; Mohammad Sajadi[8]; Cynthia Gibert[9]; Matthew S. Freiberg[10]

[1]Yale University School of Medicine, New Haven, CT, US; [2]VA Connecticut Healthcare System, West Haven, CT, US; [3]Veterans Affairs Medical Center, Atlanta, GA, US; [4]Veterans Affairs Medical Center, Houston, TX, US; [5]Sheikh Khalifa Medical City, Abu Dhabi, United Arab Emirates; [6]Veterans Affairs Medical Center, Greater Los Angeles, CA, US; [7]University of Vermont, Burlington, VT, US; [8]Veterans Affairs Medical Center, Baltimore, MD, US; [9]Veterans Affairs Medical Center, Washington, DC, US; [10]Vanderbilt University School of Medicine, Nashville, TN, US

1050 Persistently Elevated Macrophage Activation in HIV+ Women Reporting Heavy Alcohol Use

Seema N. Desai[1]; Kathleen M. Weber[2]; Jane Burke-Miller[3]; Audrey L. French[2]; Monica Gandhi[4]; Mark H. Kuniholm[5]; Elizabeth T. Golub[6]; Kendall Bryant[7]; Alan Landay[1]; Mardge Cohen[8]

[1]Rush University Medical Center, Chicago, IL, US; [2]CORE Center/Stroger Hospital of Cook County, Chicago, IL, US; [3]Hektoen Institute of Medicine, Chicago, IL, US; [4]University of California San Francisco, San Francisco, CA, US; [5]Albert Einstein College of Medicine, Bronx, NY, US; [6]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [7]National Institutes of Health/ National Institute on Alcohol Abuse and Alcoholism, Bethesda, MD, US; [8]Stroger Hospital of Cook County, Chicago, IL, US

1051 Is Survival Following HIV Seroconversion Still Improving, 17 Years After the Introduction of cART?

Ashley Olson[1]; Caroline Sabin[1]; Maria Prins[2]; Laurence Meyer[3]; Julia del Amo[4]; Genevieve Chene[5]; Osamah Hamouda[6]; Giota Touloumi[7]; Kholoud Porter[1]
On behalf of the CASCADE Collaboration in EuroCoord

[1]University College London, London, United Kingdom; [2]Public Health Service of Amsterdam, Amsterdam, Netherlands; [3]Inserm, Paris, France; [4]Instituto de Salud Carlos III, Madrid, Spain; [5]Inserm, Bordeaux, France; [6]Robert Koch Institute, Berlin, Germany; [7]University of Athens, Athens, Greece

1052 National Estimates of Life Expectancy After HIV Diagnosis: US HIV Surveillance Data

Azfar-e-Alam Siddiqi; H. Irene Hall; Xiaohong Hu; Ruiguang Song

US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US

1053 Age-Related Morbidities Among HIV-Infected Adults From 2000 to 2010

Cherise Wong[1]; Stephen J. Gange[1]; Michael A. Horberg[2]; Gregory D. Kirk[1]; Anita Rachlis[3]; John Gill[4]; Jennifer E. Thorne[1]; Robert Hogg[5]; James J. Goedert[6]; **Keri N. Althoff**[1]

[1]Johns Hopkins University, Baltimore, MD, US; [2]Mid-Atlantic Permanente Research Institute, Rockville, MD, US; [3]University of Toronto Sunnybrook Research Institute, Toronto, Canada; [4]University of Calgary, Alberta Health Services, Calgary, Canada; [5]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada; [6]National Cancer Institute (NCI), Rockville, MD, US

1054 A Retrospective Population-Based Examination of Prescription Drug Usage Prior to HIV Diagnosis Among HIV Cases and Their Controls: The Missed Opportunity for Diagnoses Epidemiological Study (MODES)

Souradet Y. Shaw[1]; Laurie Ireland[2]; Tara Carnochan[2]; Nancy Yu[1]; Carla Ens[3]; Yoav Keynan[1]; Ken Kasper[4]; Marissa Becker[1]
On behalf of the MODES Manitoba Team

[1]University of Manitoba, Winnipeg, Canada; [2]Nine Circles Community Health Centre, Winnipeg, Canada; [3]Manitoba Health, Winnipeg, Canada; [4]Manitoba HIV Program, Winnipeg, Canada

1055 Elevated Rates of Injury Among HIV-Positive Individuals in British Columbia

Hasina Samji[1]; Dmitry Shopin[1]; Wendy Zhang[1]; Oghenowede Eyawo[1]; Guillaume Colley[1]; Mark Hull[1]; Julio Montaner[3]; Robert Hogg[2]
On behalf of the COAST Study

[1]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada; [2]Simon Fraser University, Burnaby, Canada; [3]University of British Columbia, Vancouver, Canada

1056 Higher Economic Well-Being Among Virally Suppressed HIV-Infected Adults With CD4>500

Harsha Thirumurthy[1]; Aleksandra Jakubowski[1]; James G. Kahn[2]; Norton Sang[5]; Tamara Clark[2]; Edwin Charlebois[2]; Maya Petersen[3]; Moses R. Kamya[4]; Diane Havlir[2]
SEARCH Collaboration

[1]University of North Carolina at Chapel Hill, Chapel Hill, NC, US; [2]University of California San Francisco, San Francisco, CA, US; [3]University of California Berkeley School of Public Health, Berkeley, CA, US; [4]Makerere University College of Health Sciences, Kampala, Uganda; [5]KEMRI, Kisumu, Kenya

Session P-W7 Poster Session — Poster Hall

2:30 pm – 4:00 pm

HIV Stigma

1057 Internalized Stigma in a Population-Based Sample of US HIV-Infected Adults in Care

Amy R. Baugher; Linda Beer; Jennifer L. Fagan; Christine L. Mattson; Mark Freedman; Jacek Skarbinski

US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US

1058 Association Between Enacted Stigma and HIV-Related Risk Behavior Among MSM, National HIV Behavioral Surveillance System, 2011

Alexandra B. Balaji; Justin C. Smith; Kristina Bowles; Gabriela Paz-Bailey

US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US

1059 Has Antiretroviral Treatment Scale-Up in Sub-Saharan Africa Reduced HIV-Related Stigma in the General Population? A Cross-Country Analysis

Brian T. Chan[1]; Alexander Tsai[2]; Mark Siedner[2]

[1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, US; [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US

Session P-W8 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Serosorting and Seroadaptive Behavior: What's Your Position?

1060 Trends in Sexual Behaviors Among Men Who Have Sex With Men in the United States, the Role of Antiretroviral Therapy and Seroadaptive Strategies

Gabriela Paz-Bailey[1]; Maria Mendoza[1]; Binh Le[1]; Charles E. Rose[1]; Teresa Finlayson[1]; Cyprian Wejnert[1]; Henry F. Raymond[2]; Joseph Prejean[1]

[1]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US; [2]San Francisco Department of Public Health, San Francisco, CA, US

1061 Changes in Condomless Sex and Serosorting Among MSM After HIV Diagnosis

Christine M. Khosropour[2]; Julia C. Dombrowski[2]; David A. Katz[2]; Matthew R. Golden[2]

[1]University of Washington, Seattle, WA, US; [2]University of Washington, Seattle, WA, US

1062 Serosorting and Sexual Risk Behavior Influenced by Perceived HIV Serostatus Among MSM

Kathleen A. Brady; Jennifer Shinefeld; Catherine Mezzacappa

Philadelphia Department of Public Health, Philadelphia, PA, US

1063 Use of the Seroadaptive Strategies of Sexual Positioning and Serosorting by MSM in Nigeria

Cristina M. Rodriguez-Hart[1]; Hongjie Liu[2]; Ifeanyi K. Orazulike[3]; Sam Zorowitz[4]; Sylvia Adebajo[5]; Lindsay Hughes[6]; Stefan Baral[7]; Merlin L. Robb[6]; William Blattner[1]; Manhattan Charurat[1]

[1]University of Maryland School of Medicine, Baltimore, MD, US; [2]University of Maryland School of Public Health, College Park, MD, US; [3]International Center on Advocacy and Rights to Health, Abuja, Nigeria; [4]Massachusetts General Hospital and Harvard Medical School, Boston, MA, US; [5]Population Council, Abuja, Nigeria; [6]US Military HIV Research Program, Bethesda, MD, US; [7]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US

TUESDAY, FEBRUARY 24, 2015

Session P-X1 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Paying for Care

1064 Ryan White HIV/AIDS Program Assistance and HIV Treatment Outcomes in the United States

Heather Bradley[1]; Abigail H. Viall[1]; Pascale M. Wortley[1]; Antigone Dempsey[2]; Heather Hauck[2]; Jacek Skarbinski[1]

[1]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US; [2]US Health Resources and Services Administration, Rockville, MD, US

1065 Combining Multisite Payor Data With Clinical Data to Quantify Medicaid Payments for HIV Care

Anne Monroe[1]; Cindy Voss[1]; Richard Moore[1]; Kelly Gebo[1]; Allison Agwu[1]; Richard Rutstein[3]; Victoria Sharp[5]; Stephen Boswell[4]; John Fleishman[2]
The HIV Research Network

[1]Johns Hopkins University School of Medicine, Baltimore, MD, US; [2]Agency for Healthcare Research and Quality, Rockville, MD, US; [3]The Children's Hospital of Philadephia, Philadelphia, PA, US; [4]Fenway Health, Boston, MA, US; [5]Wyckoff Heights Medical Center, Brooklyn, NY, US

1066 Proportionately More Gay Men in Seattle Insured Following the Affordable Care Act

Julia E. Hood[1]; Susan E. Buskin[1]; Elizabeth A. Barash[1]; Julia C. Dombrowski[2]; Matthew R. Golden[2]

[1]Public Health–Seattle & King County, Seattle, WA, US; [2]University of Washington, Seattle, WA, US

1067 Characteristics and Outcomes of Patients Seeking Care at a New "Co-Pay" Convenience Clinic Established to Explore Sustainable Funding Models in Uganda

Rosalind M. Parkes-Ratanshi[1]; Gerald Mukisa[1]; Tom Kakaire[1]; Faridah Mayanja[1]; Adelline Tumikye[1]; Brenda Mitchell[1]; Shadia Nakalema[1]; Walter Schlech[2]

[1]Makerere University College of Health Sciences, Kampala, Uganda; [2]Dalhousie University, Halifax, Canada

WEDNESDAY, FEBRUARY 25, 2015

Session P-X2 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Linkage to and Retention in Care

1068 A Longitudinal Approach to Retention and Virologic Suppression Across the HIV Care Continuum

Jonathan Colasanti; Carlos del Rio; Wendy Armstrong

Emory University School of Medicine, Atlanta, GA, US

1069 A High Proportion of Persons Diagnosed With Acute HIV Achieve Viral Suppression

Emily Westheimer[1]; Philip J. Peters[2]; Rebekkah Robbins[3]; Sarah L. Braunstein[3]

[1]New York City Department of Health and Mental Hygiene, Queens, NY, US; [2]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US; [3]New York City Department of Health and Mental Hygiene, Queens, NY, US

1070 Drivers of HIV Treatment Success Among a Population-Based Sample of Younger Black MSM

John A. Schneider[1]; Britt Skaathun[1]; Stuart Michaels[2]; Lindsay Young[1]; Keith Green[1]; Ethan Morgan[1]; Robert W. Coombs[3]; Sam Friedman[4]; Edward Laumann[1]
On behalf of UConnect Study Team

[1]University of Chicago, Chicago, IL, US; [2]NORC, Chicago, IL, US; [3]University of Washington, Seattle, WA, US; [4]National Development Research Institute, New York, NY, US

1071 Population-Level HIV RNA and CD4+ Distribution in a Rural Ugandan Community With Widespread Community HIV Testing and Universal ART Access

Vivek Jain[1]; Gabriel Chamie[1]; Gideon Amanyire[2]; Dalsone Kwarisiima[2]; Jane Kabami[2]; Maya L. Petersen[3]; Tamara Clark[1]; Edwin D. Charlebois[1]; Moses R. Kamya[2]; Diane Havlir[1]

[1]University of California San Francisco, San Francisco, CA, US; [2]Makerere University–University of California San Francisco Research Collaboration, Kampala, Uganda; [3]University of California Berkeley School of Public Health, Berkeley, CA, US

1072 Facility-Level Factors Influencing Retention in HIV Care in East Africa

Beth Rachlis[1]; Giorgos Bakoyannis[2]; Philippa Easterbrook[3]; R. Scott Braithwaite[4]; Craig R. Cohen[5]; Elizabeth Bukusi[6]; Andrew D. Kambugu[3]; Mwebesa Bosco Bwana[7]; Elvin H. Geng[5]; Paula Braitstein[1]

[1]Academic Model Providing Access to Healthcare program, Eldoret, Kenya; [2]Indiana University, School of Medicine, Indianapolis, IN, US; [3]Infectious Diseases Institute, Kampala, Uganda; [4]New York University, New York City, NY, US; [5]University of California San Francisco (UCSF), San Francisco, CA, US; [6]Kenya Medical Research Institute, Nairobi, Kenya; [7]Mbarara University, Mbarara, Uganda

1073 Patient Retention in HIV Care Is Related to Point of Diagnosis in Western Kenya

Becky L. Genberg[1]; Hana Lee[1]; Fatma Some[2]; Joseph Hogan[1]; Paula Braitstein[3]

[1]Brown University, Providence, RI, US; [2]Moi University School of Medicine, Eldoret, Kenya; [3]Indiana University, School of Medicine, Indianapolis, IN, US

1074 Successful Down-Referral Even Among Patients With Virologic Failure in South Africa

ORAL ABSTRACTS

MONDAY, FEBRUARY 23, 2015

Session W1 Workshop **Room 6E**
9:00 am – 12:30 pm

Program Committee Workshop for New Investigators and Trainees

1 A Path to an HIV Vaccine

Galit Alter
Ragon Institute of MIT, MGH and Harvard, Cambridge, MA, US

Background: Despite our growing antiviral armamentarium and our clear appreciation on how HIV infection may be blocked, HIV continues to spread like wildfire in some communities globally. Thus a vaccine is desperately needed. The HIV vaccine community has experienced renewed optimism over the past decade due to: 1) our growing appreciation for novel unexpected immune correlates of infection in the RV144 vaccine trial that showed moderate protection from infection, as well as 2) our growing capacity to identify and mechanistically profile novel neutralizing antibodies with remarkable antiviral potency. However, despite these advances, to date, it is still incompletely understood how such responses can be induced via vaccination, or how they emerge naturally during infection.

Conclusion: This presentation will therefore highlight our current understanding of the immunological profile of "protective" anti-HIV immunity, will review the "rational" vaccine design strategies that are being exploited in the vaccine field, as well as dissect the unexplored and untapped research opporutinities in the field. Throughout the presentation, information will be provided on where and when the latest information will be presented at CROI.

2 Animal Models of HIV Prevention and Cure

Guido Silvestri
Emory University, Decatur, GA, US

While the availability of very potent anti-retroviral therapy (ART) regimens has dramatically reduced the mortality and morbidity associated with HIV infection, the absence of a safe and effective AIDS vaccine and the inability to eradicate or functionally "cure" the infection remain major challenges in contemporary HIV/AIDS research. In this context, basic and translational research in the areas of HIV pathogenesis, prevention, and therapy has long benefited from the availability of animal models that allow the in vivo testing of novel conceptual hypothesis and intervention strategies that would be virtually impossible to test in humans.

The key animal models for HIV infection are non-human primates (NHP) such as Asian macaques, that have been extensively used in studies of candidate AIDS vaccines, and natural SIV hosts, such as sooty mangabeys and African green monkeys, that have been extensively used for comparative studies of AIDS pathogenesis. More recently several types of so-called humanized mice have been developed to allow in vivo studies of the interaction between HIv and the human immune system. It must be emphasize that NHP and humanized mice represent highly synergistic models that, far from being alternative to each other, are in fact each better suited to answer specific scientific questions, and therefore should be used, ideally, as complementary aspects of comprehensive experimental strategies.

In this presentation, I will briefly review the opportunities presented by the various NHP and humanized mice models to conduct studies that will improve our understanding of AIDS virology, immunology, and pathogenesis, with specific focus on studies of HIV vaccines and eradication, including those that will be presented at CROI 2015. We hope that, ultimately, pre-clinical in vivo studies in NHPs and humanized mice will inform the design of novel prevention and therapeutic strategies for HIV infection in humans.

3 HIV Prevention 2.0: What's Next?

Susan P. Buchbinder
San Francisco Department of Public Health, San Francisco, CA, US

Background: For the first 30 years of the HIV epidemic, the 3 pillars of the prevention of sexual HIV transmission focused on HIV education, testing, and condoms. These interventions, tied to community mobilization campaigns, led to dramatic declines in HIV transmission in many communities. Substantial disparities remain in HIV incidence in vulnerable populations, particularly among men who have sex with men globally, and young women in sub-Saharan Africa. However, the last few years have demonstrated that antiretrovirals can serve as powerful prevention tools – both for blocking transmission from treated HIV infected persons and blocking acquisition for HIV-uninfected persons on pre-exposure prophylaxis (PrEP). The pillars of this second generation of HIV prevention include better HIV testing strategies; scale-up of treatment as prevention; and new PrEP agents, schedules, and delivery systems. The HIV prevention pipeline now includes many new drug formulations (including long-acting injectables and vaginal rings), some of which have reached late stage testing. Phylogenetic studies are uncovering important clues about transmission networks, and modeling studies are demonstrating reasons for ongoing disparities within vulnerable populations. We anticipate results of several pivotal trials will be available in 2015.

Conclusions: We are poised to enter the 3rd major stage of HIV prevention, combining treatment as prevention and PrEP synergistically to "turn the curve" on new HIV infections and their sequelae. Challenges in achieving high HIV prevention and treatment uptake, adherence, and retention remain; addressing these gaps is a current research priority.

4 Pathogenesis of HIV Complications

Peter W. Hunt
University of California San Francisco, San Francisco, CA, US

Background: While HIV-infected individuals with access to modern antiretroviral therapy (ART) have experienced a dramatic improvement in life expectancy, they remain at higher risk than the general population for morbidity and mortality, particularly from non-AIDS complications typically associated with aging. While lifestyle factors (e.g., smoking, illicit drug use, obesity, etc) as well as ART toxicities likely play a role, it is now well recognized that abnormal immune activation and inflammation persist in many ART-suppressed individuals, including those that restore normal CD4+ T cell counts, and that the extent of these immunologic defects strongly predicts morbidity and mortality from non-AIDS conditions. Multiple causes of the persistent inflammatory state have been proposed including HIV persistence, microbial translocation, CMV and other prevalent

co-infections. While earlier initiation of ART appears to be beneficial in reducing the inflammatory state, and some commonly used medications with anti-inflammatory properties (e.g., statins) have shown some promise in pilot studies, there is a clear need for effective interventions to reverse persistent immune activation in this setting. These issues will become increasingly important as the HIV epidemic gets older, particularly in resource-limited settings, where the vast majority of HIV-infected individuals live. Yet, the most important pathways to target with novel interventions remain unclear.

Conclusions: In the context of data being presented at CROI 2015, I will review key insights from observational studies and clinical trials that help characterize the scope of the problem of persistent immune activation in treated HIV infection. I will also highlight the importance of harnessing systems biology approaches in selecting optimal interventional targets and the need for pursuing these questions in both resource-rich and resource-limited settings.

5 HIV Cure Research

John M. Coffin

Tufts University, Boston, MA, US

Background: Although current antiretroviral therapy suppresses HIV replication and halts the otherwise inevitable progression to AIDS, it is not curative. Even after a decade or more, its interruption leads inevitably to reappearance of the virus within a few weeks. These results imply the existence of a "reservoir" of HIV-infected cells capable of producing infectious virus that can reestablish active infection when antiviral drugs are no longer present. It is important to bear in mind that the true reservoir, as so defined, is a very small fraction of the total HIV-infected cells, which are stably present in individuals on therapy, of which the large majority harbor defective and whose properties may not be represented by the majority. At present, antiretroviral drugs have to be taken for life, an unsatisfactory situation due to expense, toxicity, and risk of failure. For these reasons, a major effort is underway worldwide to develop "curative" strategies that would allow cessation of therapy without return of the virus. The proof of concept that such a therapy might be possible is given by a single example: Timothy Brown, who was HIV infected and diagnosed with acute myeloid leukemia, and received 2 allogeneic bone marrow transplants from a donor whose cells were genetically defective in CCR5, and who is still HIV-free off treatment more than 5 years later. To date this experience has not been repeated, and several recent cases of sustained suppression off therapy have ended with the return of virus months to years later, so a true cure remains a distant goal, with many active lines of research directed at a number of specific, interrelated questions. 1. What is the nature and size of the reservoir? 2. How well do in vitro models of HIV latency reflect the in vivo situation? 3. Can we develop good animal models for latency and reactivation? 3. Can we reduce the reservoir size by activating expression of latent proviruses, relying on the virus or the immune system to kill the affected cell? 4. Can we "immunize" the individual (by immune or gene therapy strategies, for example) to prevent return of the virus after cessation of therapy?

Conclusions: Despite recent advances in our understanding of hIV-1 latency as well as immunology and gene therapy, cure of HIV infection remains a distant goal. I will highlight new, exciting, and unexpected data on all of these issues and how they are advancing us toward that goal.

6 Martin Delaney Presentation: How to End the HIV Epidemic: Community Perspectives

Steven F. Wakefield

HIV Vaccine Trials Network, Seattle, WA, US

Moderator: Steven F. Wakefield, HIV Vaccine Trials Network, Fred Hutch, Seattle, WA, USA

Topics and Panel Members:

Pre-exposure Prophylaxis (PrEP): Damon L. Jacobs, LMFT, New York New York, USA

Treatment as Prevention (TasP): Connie L. Celum, MD, MPH, University of Washington, Seattle, WA, USA

Cure-Related Research: Matt Sharp, Project Inform, San Francisco, CA, USA

Background: The battle to end HIV has included the community-led safe sex movement in the 1980s, through lobbying for HIV treatments in the 1990s, to current efforts to achieve significant reductions in HIV transmission and cure research. In just over thirty years we've gone from "diagnosis = death" to "diagnosis = manageable infection" and for most, the prospect of a pretty normal lifespan. Advocacy and partnerships between communities and researchers has resulted in a sense an end is achievable.

Conclusions: Each strategy to end the epidemic presents new information and opportunities for decisions about translating science into useful strategies. A licensed marriage/family therapist / advocate from explains what it means to work with people in relationships. Noting that while trying to promote a sense of empowerment, and mental and spiritual health for people infected and affected with HIV there is need for help to negotiate the boundaries and agreements and how they discuss issues around sexuality, around sexual expression. A global health MD provides insight to trials regarding epidemiology about HIV and STIs, multi-center HIV prevention trials and the role of Treatment As Prevention (TASP) in combination community-level applications. An educator and service provider diagnosed with HIV in 1988 with a long history of advocating for AIDS treatment both participates in CURE research and teaches others to become subject matter experts on priorities, ethics and concerns as the scientific community finds a way forward.

Session W2 Workshop — Room 6E

2:30 pm – 4:30 pm

Clinical Trial Design and Analysis

7 Getting SMART About Innovative Designs for Studying Effectiveness: The Case of Adaptive Implementation Interventions

Daniel Almirall

University of Michigan, Ann Arbor, MI, US

The effective treatment and management of a wide variety of health disorders, including HIV/AIDS, often requires individualized, sequential decision-making. To do this, each patient's treatment is dynamically adapted over time based on the patient's history and changing disease state. Adaptive interventions (also known as dynamic treatment regimens) operationalize individualized decision making using a sequence of decision rules that specify whether, how, for whom, or when to alter the dose, type, or delivery of pharmacological, behavioral, and/or psychosocial treatments. Recently, there has been a surge of clinical and methodological interest in developing and evaluating adaptive interventions via clinical trials. Specifically, there is great interest in the use of sequential multiple assignment randomized trials (SMART), a type of multi-stage randomized trial design, to build high-quality adaptive interventions. The primary aim of this talk is to provide a brief, conceptual introduction on adaptive interventions and SMART designs. A secondary aim is to present the design and rationale of an example SMART which aims to develop a high-quality adaptive implementation interventions to improve the uptake/adoption of an evidence-based intervention in community settings.

8 The Clinical Pharmacology of Medication Adherence

Terrence Blaschke

Stanford University, Stanford, CA, US

Recognizing that suboptimal adherence is the major cause of treatment failure and lack of effectiveness of ARVs for PrEP, scalable interventions to improve adherence are badly needed. However, there are multiple patterns of suboptimal adherence and an understanding of the definitions and taxonomy of adherence is essential in designing interventions (Vrijens et al., Br J Clin Pharmacol. 2012; 73:691-705) Many interventions have been proposed, but to date none have been scalable and sustainable (Medication Adherence Interventions, Evidence Report No. 208. AHRQ Publication No.12-E010-EF, 2012). A limitation of most studies is the absence of reliable measures of adherence before and after an intervention. Moreover, the duration of benefit in those studies showing some increase in adherence dissipates over several months. What is needed is a scalable approach to identifying suboptimal adherence, monitoring those more likely to continue or become poorly adherent due to known predisposing factors, then focusing interventions on that cohort of patients. Due to the correspondence of drug exposure to loss of efficacy or protection from infection, sparse sampling of dosing information is insufficient, and detailed dosing information itself, shared with the patient and the provider, can significantly improve adherence. Modern technology allows detailed dosing histories to be obtained unobtrusively and collected centrally at a point in time when interventions can be applied. Combined with approaches such as Managed Problem Solving (Gross et al., JAMA Intern Med. 2013; 173:300-306) and Lifetime HIV Antiretroviral Therapy Adherence Intervention: Timing Is Everything (Bangsberg and Haberer, JAMA Intern Med. 2013; 173:306-7), progress towards scaling interventions towards populations at high risk for suboptimal adherence is now within reach.

9 Epidemiological and Biostatistical Issues in Studying Rare Events in HIV

Stephen J. Gange

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US

Studies of rare events have advanced scientific understanding of HIV prevention, treatment, and pathogenesis. While the definition of what is considered 'rare' is subjective, examples include individuals who: Remain free of HIV despite persistent high exposure; Acquire HIV in prevention studies & populations with low incidence; Exhibit extremes of disease progression: rapid disease progression, long-term survivors, elite suppressors; and/or Develop particular symptoms or disease conditions that might be the result of HIV infection, therapy, and/or comorbidities;

In this presentation, I will discuss how rare events impacts and motivates innovative methods in (1) study design options for observational and interventional investigations; (2) measurement, including methods for protecting against error and bias; and (3) causal and statistical inference, including the trend away from probabilistic-based inference and the rise of machine-learning techniques.

Session W3 Workshop — Room 6D

2:30 pm – 4:30 pm

Frontiers in Laboratory Science

10 Measuring Immunity 1 Cell at a Time

Mario Roederer

Vaccine Research Center, NIAID, NIH, Bethesda, MD, US

The immune system is comprised of incredibly diverse sets of cells, each programmed to carry out overlapping sets of effector functions. Quantifying any one function provides an incomplete view of the immune response, as information about what other responses are generated is absent. Quantifying multiple responses is far superior, but when carried out on a bulk level, loses information about cellular heterogeneity, gene programs, and a myriad of interactions that may occur at the single-cell level. Since individual cells are the atomic unit of immune function, the maximum information content is achievable only by measuring these functions independently and simultaneously on a cell-by-cell basis. For this reason, flow cytometry is a powerful technology to assess immune function in settings like vaccination and pathogenesis. Taking advantage of the ability of this technology to sort individual cells while preserving viability and nucleic acids, we can extend the multiplexing of gene expression measurements.

Recent advances in fluorescent probe technology now provides us with the capability to simultaneously and independently quantify more than 30 cell-associated proteins with unheralded sensitivity. Integrating this technology with single cell transcriptomics provides a unique view of cellular functions. We choose to quantify lymphocyte-centric genes, including those encoding transcription factors, signaling molecules, effector molecules, and regulatory molecules. On a single-cell basis, we can correlate protein expression with gene expression; e.g., discordant results for the same gene reveal post-transcriptional regulatory mechanisms.

We have identified gene signatures associated with vaccine-elicited T cells as well as with productively SIV-infected cells in vivo. This technology gives us an unprecedented view into the complexity and range of immunological functions expressed by vaccine or virus-specific immune cells. Using this approach, we can search for correlates of clinical outcome based on either: quantitative gene expression; and/or cell subset representation, enumerated by groups of cells sharing gene expression profiles. These analyses give us new insights into functional immune states in pathogenesis, treatment, and vaccination.

11 Studying Heterogeneity With Single Cell RNA-Sequencing

Simon Quenneville

Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland

Heterogeneity is a complicated problem to study. In many contexts, researchers use purified or cultured cells, treating them as a uniform population, while often a certain degree of heterogeneity is present. Treated in bulk, the large amount of individual will allow the buffering of extreme phenotypes. Heterogeneity is often suspected, but the means of exploring the phenomena were lacking. Recently, RNA-seq technology as been optimized for single-cell analysis. This allows us to look at expression levels of a large number of individual cells and genes to describe subpopulations. We have used this method to investigate specific problems in HIV infection, I will use our example to describe the huge possibilities of this technique.

We and others have observed heterogeneity: activated CD4 T cells are not all permissive to HIV infection. For example, infecting activated cells with increasing doses of HIV particles leads to a maximum level of transduction. This maximum is also variable between individuals, ranging from a few percent cells being susceptible up to more than half. Purifying infected cells followed by a comparison with uninfected cells is interesting, but the infectious process itself is altering transcription. Single cell RNA-seq allowed us to investigate the heterogeneity in CD4 T cell population coming from permissive and non-permissive donors. We have been looking for subpopulations with differential permissivity, but also for cell markers that would allow us to identify and purify the "permissive sub-population". This presentation will overview the process, flaws and limitation of this technique and describes the pipeline we are developing.

12 Integration-Site Analysis

Frederic D. Bushman

University of Pennsylvania School of Medicine, Philadelphia, PA, US

Background: The lecture will cover analysis of HIV DNA integration sites in model systems, in HIV infected patients, and in human gene therapy.

Methods: With the development of efficient methods for DNA sequence acquistion, it has become possible to study the geomic locations of populations of integrated proviruses.

Results: Early studies showed that HIV favors integration target sites within active transcription units quite strongly. This is mediated in part by tethering to the human transcriptional mediator protein LEDGF/p75. Quantification of integration site recovery can be challenging due to distortions in abudance during PCR and other steps—however tracking using the SonicAbundance method overcomes many of these limitations. These methods and a suite of custom bioinformatic tools have been applied to samples of HIV-infected patients and human subjects gene-corrected with lentiviral vectors.

Conclusions: Analysis of integration site data can involve a number of challenges—new approaches to analysis and data visualizaiton will be presented.

13 Discovery and Modeling of Genomic Regulatory Networks With Big Data

Hamid Bolouri

Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US

High throughput sequencing, large-scale data generation projects, and web-based cloud computing are changing how computational biology is performed, who performs it, and what biological insights it can deliver. Here I review the latest developments in available data, methods and software focusing on the modeling and analysis of the gene regulatory interactions in cells. Three key findings are: (A) Although sophisticated computational resources are increasingly available to bench biologists., tailored on-going education is needed to avoid the erroneous use of these resources. (B) Current models of the regulation of gene expression are far too simplistic and need updating. (C) Integrative computational analysis of large-scale datasets is becoming a fundamental component of molecular biology. I discuss current and near term opportunities and challenges related to these three points.

Session W4 Workshop — Room 613

2:30 pm – 4:30 pm

Hepatitis C Care in the Interferon-Free Era

14 Acute HCV: Is It Still Important to Diagnose and Treat?

Arthur Y. Kim

Massachusetts General Hospital, Harvard Medical School, Boston, MA, US

With the advent of 12 week therapies for chronic HCV with high efficacy, the impetus for early identification the acute phase of infection is no longer based on enhanced treatment efficacy. Instead, the rationale for identifying infection is to provide important counseling and care aimed at enhancing personal health and preventing secondary cases. Ongoing trials will determine whether shorter and/or less intensive courses of antivirals during the acute phase of infection will result in excellent cure rates and preserve immune responses that may be important in the prevention of reinfection after viral clearance.

15 Chronic Genotype 1 Infection

Debika Bhattacharya

University of California Los Angeles CARE Center, Los Angeles, CA, US

We will discuss major management issues specific to chronic genotype 1 infection, including methods of disease staging, timing of treatment initation, regimens for treatment, and monitoring during and after treatment.

16 HCV Genotype 3: Our Next Challenge

Arthur Y. Kim

Massachusetts General Hospital, Harvard Medical School, Boston, MA, US

While novel therapies are able to cure the vast majority of individulas with genotype 1, those with genotype 3 have less robust options. Given that it is prevalent throughout the world and is emerging in young injection drug users, advancing therapeutic options for genotype 3 is one of our next challenges. By presenting a case of a prior nonresponder to interferon-based therapies, current and future management options for genotype 3 will be highlighted.

17 HCV Cirrhotics With Early Decompensation

Marion G. Peters

University of California San Francisco, San Francisco, CA, US

HCV cirrhotics decompensate at 5-7% per year with development of varices, ascites, hepatic encephalopathy or synthetic dysfunction. All cirrhotics should be monitored for hepatocellular carcinoma (1-4% develop HCC per year). Ultrasonography is recommended every 6 months (estimated doubling time of HCC 136 days). Quadruple–phase computed tomography or MRI is used to confirm any abnormalities seen. Cirrhotics should undergo upper endoscopy to evaluate for varices. If Grade 2 or greater varices are found, primary prophylaxis with a non-selective beta blocker (propranolol or nadolol) should be initiated to decrease the heart rate by 10%. If beta blockers cannot be tolerated, then band ligation of varices is recommended. Transjugular intrahepatic portosystemic shunting (TIPS) promptly drops portal pressure.

All patients with ascites require diagnostic paracentesis to evaluate for portal hypertension and to exclude spontaneous bacterial peritonitis. Portal hypertension is suggested when serum to ascites albumin gradient is ≥1.1 mg/dL. Management of ascites includes sodium restriction (<2 g/day) and diuretics: spironolactone combined with furosemide (ratio of 40 mg furosemide: 100 mg spironolactone, increasing as needed). With progression, ascites becomes diuretic refractory and treatment usually requires large-volume paracentesis (LVP) or TIPS. For every liter of ascites removed, 50 cc of 25% salt poor albumin iv must be given. While TIPS is associated with greater transplant-free survival than LVP, it also has a much higher rate of hepatic encephalopathy.

The new all oral direct acting antiviral agents (DAA) for HCV have permanently changed the treatment landscape for patients with end stage HCV. The current AASLD/IDSA 2014 guidelines (http://www.hcvguidelines.org) recommend that patients with decompensated cirrhosis should have an experienced HCV treater and be referred for liver transplant evaluation. Recommended regimens for genotype 1 and 4 are daily fixed-dose combination ledipasvir (90 mg)/sofosbuvir (400 mg) with RBV for 12 weeks in naïve patients, and 24 weeks in prior sofosbuvir failures. If RBV intolerant, daily fixed-dose combination ledipasvir (90 mg)/sofosbuvir (400 mg) for 24 weeks is recommended. The regimen for Genotype

2 and 3 HCV patients with decompensated cirrhosis is daily sofosbuvir (400 mg) and weight-based RBV for up to 48 weeks. However, these patients may have lower SVR and ongoing decompensation, so careful monitoring is required.

Bernard Fields Lecture

18 Hepatitis C: Light at the End of the Tunnel

Charles M. Rice
The Rockefeller University, New York, NY, US

An estimated 200 million people have been infected with hepatitis C virus (HCV) with a majority unable to clear the virus. Chronic HCV infection can lead to cirrhosis, hepatocellular carcinoma, and end-stage liver disease. It is generally believed that disease results at least in part from immune mediated inflammation. Since HCV's discovery in 1989 significant progress has been made in establishing experimental systems and unraveling the details of the virus lifecycle. Examples include viral enzyme assays, infectious molecular clones, RNA replicons and finally robust cell culture systems recapitulating the entire virus lifecycle. Definition of the human factors required for HCV entry and blunting innate immune response pathways has led to the development of a mouse model that supports HCV entry, replication and virus production. Together these tools have increased our understanding of the HCV lifecycle and revealed multiple steps for therapeutic intervention. Although painstakingly slow at times, we are finally at the cusp of a revolution in HCV treatment with the advent of well tolerated, all oral, pan genotype regimens that can achieve virologic cure rates in excess of 95%. Challenges remain but we now have the tools in hand to write the final chapter of a remarkable biomedical success story.

Session NL2 Lecture
N'Galy-Mann Lecture

19 Antiretroviral Therapy: Past, Present, and Future

David A. Cooper
Kirby Institute, University of New South Wales, Sydney, Australia

Antiretroviral therapy has saved countless lives. However, we know it to be imperfect and we are always looking for ways to improve outcomes. For treatment-naïve patients, it is time either to optimise the dose of efavirenz, or replace it altogether with integrase inhibitors in combination with two nucleosides. For people requiring a second-line treatment, new studies have confirmed the current WHO standard of care but also indicated a novel approach of two new classes of drug therapy in combination, as a public health approach without the need for resistance testing. This brings us to early treatment, which is now simple, non-toxic and beneficial in reducing transmission, but about which there has been controversy in the context of insufficient resources to cover the existing number of people needing treatment.

Session PL-1 Plenary **4AB Auditorium**
8:30 am – 9:00 am

PrEP for HIV Prevention: What We Know and What We Need to Know for Implementation

20 PrEP for HIV Prevention: What We Know and What We Still Need to Know for Implementation

Raphael J. Landovitz
University of California Los Angeles, Los Angeles, CA, US

Tenofovir-based pre-exposure prophylaxis (PrEP) prevents HIV transmission in diverse populations. Randomized controlled trials demonstrate high levels of protection against sexually transmitted HIV for men who have sex with men (MSM) and heterosexual men and women. There are less robust data supporting the use of PrEP for prevention of parenteral transmission. Enthusiasm for widespread PrEP use is dampened by concerns about safety (both near and long term), requirements for daily or near-daily dosing, potential for viral resistance, cost, and behavioral risk compensation (increases in numbers of partners and/or less frequent condom use).

Open-label "demonstration" projects are currently under way to evaluate acceptability and uptake by at-risk populations, longer-term safety, real-world adherence, the consequences of less frequent clinical evaluations, cost effectiveness, and behavioral change. Novel adherence measures will advance our understanding of patterns of PrEP dosing, coverage of sexual activity, and the optimal support mechanisms for successful PrEP use.

Transitioning demonstration project participants to clinical care and an increased interest in PrEP have posed new and difficult challenges: What type of provider should be delivering PrEP services? What are the optimal locations for PrEP initiation and follow-up? What is known about sufficient and optimal dosing regimens? What will be the adverse event profile in real-world settings? Will there be increased resistance with more widespread PrEP use? How will PrEP be financed? How can we educate providers, public health bodies, and potential consumers – particularly those most at risk – about PrEP? What are the optimal HIV testing intervals and algorithms?

The success thus far of tenofovir-based PrEP in both clinical trials and increasingly in clinical practice, other PrEP strategies are under active investigation. These include agents that are not nucleoside analogue reverse transcriptase inhibitors, topical and long-acting injectable formulations, as well as novel preparations of new and existing antivirals. Formidable questions remain as to how to operationalize, facilitate, and streamline PrEP access to populations most at-risk for HIV acquisition locally and globally.

Session PL-2 Plenary **4AB Auditorium**

9:00 am – 9:30 am

Specific HIV Integration Sites Linked to Clonal Expansion and Persistence of Cells

21 Specific HIV Integration Sites Linked to Clonal Expansion and Persistence of Cells

Stephen H. Hughes

National Cancer Institute, Frederick, MD, US

Background: The persistence of HIV-infected cells in individuals on suppressive combination antiretroviral therapy (cART) presents a major barrier for curing HIV infections.

Methods: HIV integrates its DNA into many sites in the host genome; thus integration sites can be used as markers to identify clonally expanded cells. We identified the integration sites in PBMCs and CD4+ T cells from patients and used the data to analyze the clonal expansion of infected cells. We have started to determine the sequences of viral DNAs in clonally expanded cells; these sequences are being used to study the expression of the proviruses in the expanded cells.

Results: We have identified >2500 integration sites in PBMCs and CD4+ cells of infected individuals on cART. About 40% of the integrations were in clonally expanded cells. In one patient, more than 50% of the infected cells were from a single clone; some of the expanded clones persisted for more than 10 years. There were multiple independent integrations in the same orientation as the gene in two introns of the MKL2 and BACH2 genes; many of these integrations were in clonally expanded cells. Both BACH2 and MKL2 are involved in regulating the growth of cells. DNA rearrangements involving these genes are present in human tumors. There was no evidence forintegration in one orientation, or in specific introns, in either of these genes in large libraries prepared by infecting stimulated or unstimulated PBMCs, CD34+ cells, or HeLa cells in culture. There were, in patients, multiple independent integrations in a number of other growth related genes, many of which were associated with clonal expansion of the infected cells. These data show that HIV integration at certain sites can play a critical role in the expansion and persistence of HIV infected cells. In one case, we showed that the provirus in an expanded clone was responsible for producing the majority of the virus that was present in the blood of a patient. This shows that, in this patient, immune surveillance was not sufficient to prevent clonally expanded cells from producing virions.

Conclusions: Our findings have important implications for the development and maintenance of the viral reservoir, for designing and implementing strategies to eliminate persistent HIV infection, for the use of lentiviral vectors for gene therapy in human patients, and, possibly, for the origin of some HIV-related malignancies.

Session O-1 Oral Abstracts **Room 6AB**

10:00 am – 12:15 pm

Preventing HIV and HSV-2: What Will It Take?

22LB Pragmatic Open-Label Randomised Trial of Preexposure Prophylaxis: The PROUD Study

Sheena McCormack; David Dunn
On behalf of the PROUD Study Group

MRC Clinical Trials Unit at University College London, London, United Kingdom

Background: Randomised placebo-controlled trials have clearly demonstrated that tenofovir/emtricitabine (TDF/FTC), when taken regularly as PrEP, reduces the risk of HIV infection. However, there are concerns that this benefit might be counteracted by users of PrEP engaging in riskier sexual practices, increasing their chance of exposure to HIV and other STIs. This supports the need for pragmatic open-label randomised studies which mimic real-life clinical practice.

Methods: The PROUD study enrolled MSM from 13 sexual health clinics in England between 27Nov2012 and 30Apr2014. Eligibility criteria included a negative HIV test in the previous 4 weeks and reported condomless anal intercourse in the previous 90 days. MSM were randomised 1:1 to receive open-label daily TDF/FTC either immediately (IMM) or after a deferral (DEF) period of 12 months, and followed quarterly. Based on early demonstration of efficacy, the TSC/IDMC recommended on 13Oct2014 that all MSM in the deferral period be offered PrEP. All analyses are modified ITT (excluding 3 MSM with a reactive HIV test at baseline) based on person-years (PY) to the first HIV test after 48 weeks or after 13Oct2014, whichever was earlier.

Results: 545 MSM were randomised (276 IMM, 269 DEF). At baseline, median(IQR) age was 35(30-43) and 81% were white; median(IQR) number of anal sex partners in the previous 90 days was 10(4-20); 64% reported a diagnosed STI in the previous 12 months. 20 MSM (5 IMM, 15 DEF) had no HIV test after baseline; completeness of follow-up for HIV incidence was 91% (237/261 PY) for IMM and 89% (216/242 PY) for DEF. Three HIV infections were observed in IMM (1.3/100 PY); 19 infections were observed in DEF (8.9/100 PY) despite 174 prescriptions of post-exposure prophylaxis (PEP). This yields a rate difference of 7.6/100 PY (90%CI 4.1-11.2) and a relative reduction of 86% (62-96%; P=0.0002). The proportion with a confirmed STI indicative of condomless anal intercourse (rectal chlamydia/gonorrhoea) was similar in IMM (29%) and DEF (27%) (P=0.50).

Conclusions: In this high incidence cohort, daily TDF/FTC conferred impressive protection against HIV, and higher than the levels previously observed in the placebo-controlled trials. Concerns that effectiveness would be undermined in a real-world setting were unfounded. There was no evidence of an increase in STIs in this population, although they were frequently reported in the year before enrolment. This result strongly supports the use of PrEP among MSM who are at risk of HIV infection.

23LB On Demand PrEP With Oral TDF-FTC in MSM: Results of the ANRS Ipergay Trial

Jean-Michel Molina[1]; Catherine Capitant[2]; Bruno Spire[3]; Gilles Pialoux[4]; Christian Chidiac[5]; Isabelle Charreau[2]; Cecile Tremblay[7]; Laurence Meyer[2]; Jean-Francois Delfraissy[6]
And the ANRS Ipergay Study Group

[1]University of Paris Diderot, Paris, France; [2]Inserm SC10 US019, Villejuif, France; [3]Inserm U912, Marseille, France; [4]Hopital Tenon, APHP, Paris, France; [5]Hopital de la Croix Rousse, Lyon, France; [6]ANRS, Paris, France; [7]CHUM, Montreal, Canada

Background: Daily PrEP with oral TDF-FTC can reduce the risk of HIV infection in high risk individuals but long term adherence to a daily regimen remains challenging and explains the discordant results reported across trials. We wished to assess the efficacy of "on demand" PrEP in high risk MSM.

Methods: High risk adult MSM who reported condomless anal sex and had a creatinine clearance > 60 mL/mn were enrolled in this prospective randomized double-blinded placebo-controlled study. Participants (pts) were asked to take two pills of TDF-FTC (300mg/200mg per pill) or placebo 2 to 24h before each sexual intercourse, then another pill 24h later and a fourth pill 48h after the first drug intake. All subjects received risk-reduction counseling, condoms, HBV and HAV vaccines when needed, were informed about post-exposure prophylaxis and were regularly tested for HIV and other sexually transmitted infections (STIs). The primary study objective was to demonstrate a reduction in HIV incidence with on demand PrEP. In November 2014, following the DSMB recommendation, the placebo arm was discontinued and on demand PrEP was offered to all participants.

Results: From February 2012 to November 2014, 414 pts were randomized and 400 without HIV-infection were enrolled. After a median follow-up of 8.8 months (IQR: 4.3 to 20.5), the incidence of HIV-infection was 6.75 per 100 pt-years in the placebo arm and 0.94 per 100 pt-years in the TDF-FTC arm indicating a relative reduction of 86% in the incidence of HIV with on demand PrEP (95%CI: 39.4-98.5%, P=0.002). Sixteen pts acquired HIV-infection after enrollment, 14 in the placebo arm and 2 in the TDF-FTC arm. Pts used a median of

14 pills/month (IQR: 8-20). Overall, 34% of pts acquired a new STIs. Safety was good with only one pt discontinuing TDF-FTC because of suspected drug-drug interaction. The rate of serious adverse events was low (9%) and similar across the study arms. Drug-related gastrointestinal adverse events (nausea, diarrhea, abdominal pain) were reported more frequently with TDF-FTC than with placebo (13% vs 6%, p=0.02). Only 2 pts (1%) in the TDF-FTC arm had transient decreases in creatinine clearance < 60 mL/mn.

Conclusions: On demand PrEP with oral TDF-FTC is highly effective to reduce the incidence of HIV-infection in high risk MSM and has a good safety profile.

24 Near Elimination of HIV Transmission in a Demonstration Project of PrEP and ART

Jared Baeten[1]; Renee Heffron[1]; Lara Kidoguchi[1]; Nelly Mugo[2]; Elly Katabira[3]; Elizabeth Bukusi[2]; Stephen Asiimwe[4]; Jessica Haberer[5]; Deborah Donnell[6]; Connie Celum[1]

[1]University of Washington, Seattle, WA, US; [2]Kenya Medical Research Institute, Nairobi, Kenya; [3]Makerere University College of Health Sciences, Kampala, Uganda; [4]Kabwohe Clinical Research Centre, Kabwohe, Uganda; [5]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [6]Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US

Background: Antiretroviral-based HIV prevention interventions, including pre-exposure prophylaxis (PrEP) and antiretroviral therapy (ART), showed high efficacy for HIV protection in clinical trials among African HIV serodiscordant couples. Assessing the effectiveness of these interventions, and their ability to complement one another, in implementation settings is a priority.

Methods: We are conducting the Partners Demonstration Project, an open-label, prospective study of PrEP and ART delivery among antiretroviral-naïve high-risk heterosexual HIV serodiscordant couples in Kenya and Uganda. High-risk couples are defined by a validated risk scoring tool (Kahle et al., JAIDS 2013). PrEP is offered as a 'bridge' to ART in the partnership – i.e., until ART initiation by the HIV-infected partner and for the first 6 months after ART is started; ART is recommended following national ART guidelines – initially CD4 <350 cells/μL but more recently all HIV serodiscordant couples regardless of CD4 count. To assess the impact of the PrEP as a bridge to ART strategy on HIV transmission, we compared observed HIV incidence to a counterfactual simulation model, using bootstrapping methods and constructed with data from a prior prospective study of HIV serodiscordant couples (the Partners PrEP Study, placebo arm), sampled selecting for a subset with an identical distribution of risk scores and duration of follow-up.

Results: Enrollment in the Partners Demonstration Project began in November 2012 and completed in August 2014, with a final sample size of 1013 couples. Given the risk score distribution of the study population, the counterfactual simulations predicted 21.7 HIV infections would be expected to date in this population (incidence 5.3 per 100 person-years, 95% CI 3.2-7.6). However, through July 2014, only one incident HIV infection has been observed during 440 person-years of follow-up, for an observed HIV incidence of 0.2 per 100 person-years (95% CI 0.0-1.3, p<0.0001 versus predicted) (Figure). PrEP was used during 47% of the 440 person-years of follow-up, ART 17%, both 25%, and neither 11%.The one transmission occurred in the absence of ART and with evidence of low PrEP adherence.

Conclusions: Early results from this demonstration project integrating time-limited PrEP and ART for HIV prevention in African couples show near elimination of HIV transmission, with an observed HIV incidence <0.5% per year compared to an expected incidence >5% per year.

25 Scale-Up of Preexposure Prophylaxis in San Francisco to Impact HIV Incidence

Robert M. Grant[3]; Albert Liu[2]; Jen Hecht[4]; Susan P. Buchbinder[2]; Shannon Weber[1]; Pierre-Cedric Crouch[4]; Steven Gibson[4]; Stephanie Cohen[2]; David Glidden[1]

[1]University of California San Francisco (UCSF), San Francisco, CA, US; [2]San Francisco Department of Public Health, San Francisco, CA, US; [3]Gladstone Institutes, San Francisco, CA, US; [4]San Francisco AIDS Foundation, San Francisco, CA, US

Background: Since 2007, rates of new HIV diagnoses in San Francisco (SF) decreased with widespread HIV testing, pooled HIV RNA testing for high-risk seronegatives, increased viral suppression rates, and grass-roots initiatives. Consumer demand for pre-exposure prophylaxis (PrEP) has increased since mid-2013. Local goals for PrEP scale-up have not been established.

Methods: A simple model was developed to forecast HIV transmission with expanded PrEP use. The model considers infectiousness and partnering practices of diagnosed and undiagnosed persons with HIV infection, viral suppression rates, and transmission to uninfected people having low, moderate, or high numbers of partners. Model parameters for SF were derived from surveillance, local research on seroadaptive behaviors, and SF-specific data from cohort studies, including the iPrEx Open Label Extension (OLE). Adherence in OLE was monitored by drug concentrations in dried blood spots and mapped to efficacy using global iPrEx data. The optimistic scenario assumes PrEP uptake will attract and retain people with higher exposure to HIV, as was observed at SF's OLE site. The realistic scenario assumes incidence rates that are typically observed in SF cohorts that did not include access to PrEP.

Results: In SF, the HIV diagnosis rate is 94% with 67% viral suppression. Among 150 eligible participants in OLE in SF, 64% chose to start PrEP; People starting PrEP were more likely to report non-condom receptive anal intercourse (44% vs 26%; P=0.03). Adherence yielded substantially protective drug concentrations among 96% of users through week 24, falling slightly afterward. If PrEP were used by 6400 people in the optimistic scenario (incidence 1.3 to 4.2/100py), the number of new infections could fall by 50% city-wide; doubling the number on PrEP could reduce new infections to less than 50 per year, a 86% reduction. In the realistic scenario (incidence 0.8 to 2.5/100 py), the city-wide incidence falls by 30% with 6400 people on PrEP; getting to less than 50 cases a year requires that diagnosis rates increase to over 99% with 90% viral suppression, at which point PrEP's impact on HIV incidence decreases because exposure to untreated HIV infection would be rare.

Conclusions: Demand for PrEP is increasing in SF with high rates of adherence. Widespread use of PrEP could markedly decrease new HIV infections, especially if synergies between PrEP uptake and adherence, HIV exposure, and HIV testing continue during PrEP rollout.

26LB FACTS 001 Phase III Trial of Pericoital Tenofovir 1% Gel for HIV Prevention in Women

Helen Rees[1]; Sinead A. Delany-Moretlwe[1]; Carl Lombard[2]; Deborah Baron[1]; Ravindre Panchia[4]; Landon Myer[3]; Jill L. Schwartz[5]; Gustavo F. Doncel[5]; Glenda Gray[2]
On behalf of the FACTS 001 Study Team

[1]Wits Reproductive Health and HIV Institute, Johannesburg, South Africa; [2]South African Medical Research Council, Cape Town, South Africa; [3]University of Cape Town, Cape Town, South Africa; [4]Perinatal HIV Research Unit, Soweto, South Africa; [5]CONRAD, Arlington, VA, US

Background: HIV prevention in women is a major public health priority. Pericoital vaginal application of tenofovir (TFV) gel has been demonstrated to prevent male-to-female HIV transmission in a proof of concept phase IIB trial. However, adherence to product is a critical driver of microbicide effectiveness. Additional data are required for licensure.

Methods: FACTS 001 is a phase III, multi-centre, double-blind, randomised, placebo-controlled trial undertaken in 9 sites in South Africa which evaluated the safety and effectiveness of pericoital TFV 1% gel when using the BAT-24 regimen (before and after sex; no more than 2 doses in 24h). HIV-negative women aged 18-30 years received intensive counselling on product adherence and HIV risk reduction with condom provision. Monthly follow-up visits included HIV and safety testing, return of unused product and used gel applicators, and ongoing counselling on product adherence for up to 27 months. Product adherence was measured by proportion of self-reported sex acts covered by gel. In the primary intent-to-treat analysis, the effectiveness of TFV gel was assessed using a log-rank test stratified by site. A nested case-cohort substudy (n=214) also examined TFV drug levels in quarterly cervicovaginal lavage (CVL) samples in HIV seroconverters vs controls.

Results: Between Oct 2011 and Aug 2014, 3844 participants were screened, 2059 enrolled and 2029 included in the primary analysis. At enrolment, participant mean age was 23 years, most were unmarried (88%), lived with parents (62%), and had earned ⟨US$100 in the past 3 months (73%). 3036 person-years of observation were accrued and 7.4% of participants were lost to follow-up. Overall 123 HIV infections occurred (HIV incidence: 4.0/100 women years); 61 in the TFV arm and 62 in the placebo group (incidence rate

ratio [IRR], 1.0; 95% CI: 0.7-1.4). TFV gel effectiveness was highest in women who reported product use in 〉72% of sex acts (IRR 0.43; 95% CI 0.09-1.61); however, this subgroup represented only 20% of participants. In the case-cohort substudy, high TFV in CVL was significantly associated with a reduction in HIV acquisition (HR: 0.52; 95% CI: 0.27-0.99; p=0.04).

Conclusions: In this trial, pericoital vaginal TFV 1% gel was not effective in preventing HIV acquisition. In a stratified analysis, there was an association between adherence based on returned applicators and HIV effectiveness, and a significant association between TFV levels in CVL and reduction in HIV incidence.

27 Effect of Oral and Gel Tenofovir on Genital HSV Shedding in Immunocompetent Women

Rachel A. Bender Ignacio[1]; Tara Perti[2]; Amalia S. Magaret[1]; Sharanya Rajagopal[1]; Meei-Lee W. Huang[1]; Christine M. Johnston[1]; Stacy Selke[1]; Jeanne M. Marrazzo[1]; Anna Wald[1]

[1]University of Washington, Seattle, WA, US; [2]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US

Background: Tenofovir is a potent anti-HIV agent with efficacy in studies of pre-exposure prophylaxis when taken orally or used as intravaginal gel. Recent studies suggest that tenofovir also reduces the risk of HSV-2 acquisition. Whether oral or gel tenofovir may be useful in HSV disease management, or to decrease HIV and HSV-2 transmission from co-infected persons, is unclear.

Methods: We randomized immunocompetent women with symptomatic HSV-2 infection 2:2:1 to oral tenofovir disoproxil fumarate (TDF)/placebo vaginal gel, oral placebo/tenofovir (TFV) vaginal gel, or double placebo in a one-way cross-over clinical trial. Women collected twice daily genital swabs for HSV PCR and completed symptom diaries during a 4-week lead-in and 5 week treatment phase. The primary intent-to-treat analysis was within-arm comparison of shedding rates and genital lesions with Poisson generalized linear mixed effects models and shedding quantity with a linear mixed-effects model.

Results: 73 women were enrolled and 64 completed the lead-in observation phase and were randomized: 24 women to TDF, 27 to TFV gel, and 13 to placebo. Relative to baseline, genital HSV shedding showed a small decrease from 22.9% to 19.5% (RR=0.86 p=0.09) in the TDF arm, but did not differ in the TFV gel arm (13.8% versus 12.0%; RR=0.94, p=0.54) or in the placebo arm (21.3% versus 20.4%; RR=0.90, p=0.45; Table 1). Asymptomatic shedding decreased in the TDF arm only (RR=0.74, p=0.01). There was no change in days with HSV lesions or number of shedding episodes. Shedding quantity decreased by 0.50 $\log_{10}$ copies in the TFV gel arm (p=0.008), but remained consistent in the TDF (p=0.18) and placebo arms (p=0.45). The per-protocol analysis included 20 women in the TDF arm, 20 in the TFV gel arm, and 9 in the placebo arm who completed 33 days of study product with 90% adherence. Relative to baseline, the shedding frequency was reduced in the TDF arm (RR=0.74, p=0.006), and quantity was reduced in the TDF (0.41 log) and TFV gel arms (0.6 log); other findings were similar to the full cohort. The TDF and TFV products were both well tolerated, and adherence was 97% by returned product count in all arms.

Risks of HSV-2 Shedding and Lesions by Study Arm

	Intent to Treat			Per protocol		
	Oral Tenofovir RR (p)	Gel Tenofovir RR (p)	Placebo RR (p)	Oral Tenofovir RR (p)	Gel Tenofovir RR (p)	Placebo RR (p)
Genital Shedding	0.86 (0.086)	0.94 (0.54)	0.90 (0.47)	0.74 (0.006)	0.95 (0.69)	0.78 (0.11)
Asymptomatic Shedding	0.74 (0.010)	1.30 (0.090)	0.75 (0.15)	0.69 (0.006)	1.38 (0.085)	0.73 (0.12)
Lesions	0.98 (0.90)	0.80 (0.25)	0.95 (0.82)	0.75 (0.032)	0.81 (0.15)	0.75 (0.11)
HSV quantity (change in $\log_{10}$ copies)	-0.16 (0.18)	-0.50 (0.008)	0.16 (0.45)	-0.41 (0.004)	-0.60 (0.003)	0.18 (0.42)

Conclusions: Oral TDF causes small reductions in shedding and lesion rate, and quantity of virus shed when used consistently. Vaginal TFV gel decreases shedding quantity by 60%. In contrast to evidence that oral and gel tenofovir may reduce HSV-2 acquisition, benefits in treatment of established HSV-2 infection are minimal.

28 Injectable Hormonal Contraception Use and Women's Risk for HSV-2 Acquisition

Mary K. Grabowski[1]; Ronald H. Gray[1]; Fred Makumbi[2]; Joseph Kagaayi[2]; Andrew D. Redd[3]; Fred Nalugoda[2]; Maria J. Wawer[1]; David Serwadda[4]; Thomas C. Quinn[3]; Aaron A. Tobian[5]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [2]Rakai Health Sciences Program, Kalisizo, Uganda; [3]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD, US; [4]Makerere University College of Health Sciences, Kampala, Uganda; [5]Johns Hopkins University, Baltimore, MD, US

Background: Injectable hormonal contraception (HC) use has been associated with increased risk of HIV acquisition in women, but findings are inconsistent. The pathophysiology of how injectable HC use might increase HIV risk is unclear. Heightened risk for other sexually transmitted infections (STI) has been postulated as a possible mechanism, but it is unknown if injectable HC increases risk for other viral STIs. We assessed the association between oral and injectable HC use and incident herpes simplex virus type 2 (HSV-2), which is a risk factor for HIV acquisition.

Methods: Risk of incident HSV-2 associated with HC use was assessed among 682 HIV and HSV-2-negative women whose HIV-negative male partners were enrolled in a trial of medical male circumcision in Rakai, Uganda. Women were followed annually over two years. HSV-2 incidence was compared among women using injectable HC stratified into consistent, newly initiated, or discontinued use between visits, women using oral HC, pregnant women, and women who were neither pregnant nor using HC (referent group). Hazard ratios (HR) were estimated using discrete-time Cox proportional hazards models with adjustment for demographics, sexual behaviors, and condom use.

Results: We identified 70 incident HSV-2 events. Incidence was 13.1/100 person-years (py) among women consistently using injectable HC, and 3.9 and 5.2/100 py among women initiating and discontinuing injectable HC, respectively. Incidence was 2.8/100 py among oral HC users, while among non-HC users, incidence was 4.3/100 py in pregnant women and 6.6/100 py in non-pregnant non-HC using women. Compared to women who were neither pregnant nor using HC, the adjusted hazard ratio of HSV-2 acquisition among women consistently using injectable HC was 2.26 (95%CI: 1.09-4.69, p=0.029). Among 132 women with HSV-2 positive partners, incidence was 36.4/100 py in consistent injectable HC users and 10.6/100 py in women who were neither pregnant nor using HC (adjHR: 6.23; 1.49-26.3, p=0.012). There was no increased risk for HSV-2 among women who recently initiated or discontinued injectable HC, oral HC users, or pregnant women.

Conclusions: Our data suggest consistent use of injectable HC is associated with increased risk of HSV-2 acquisition. The findings may be relevant to the associations between HIV risk and use of injectable HC in some prior studies, and might indicate that injectable methods broadly affect the risk of viral sexually transmitted infections in women.

29 Effect of Financial Incentives on Linkage to Care and Viral Suppression: HPTN 065

Wafaa M. El-Sadr[1]; Bernard M. Branson[2]; Gheetha Beauchamp[3]; H. Irene Hall[2]; Lucia V. Torian[4]; Barry S. Zingman[5]; Garret Lum[6]; Rick Elion[7]; Theresa Gamble[8]; Deborah Donnell[3]

[1]ICAP at Columbia University, New York, NY, US; [2]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US; [3]SCHARP, Fred Hutchinson Cancer Research Center, Seattle, WA, US; [4]New York City Department of Health and Mental Hygiene, New York, NY, US; [5]Montefiore Medical Center, University Hospital for Albert Einstein College of Medicine, New York, NY, US; [6]District of Columbia Department of Health, Washington, DC, US; [7]Whitman-Walker Health, Washington, DC, US; [8]FHI360, Durham, NC, US

Background: Enhancing the HIV continuum is critical. HPTN 065 evaluated the effect of financial incentives (FI) on linkage to care (L2C) and viral suppression (VS) in Bronx, NY (BNY) and Washington, DC (DC).

Methods: A total of 34 (16BNY/18DC) HIV test sites and 37 (20 BNY/ 17 DC) care sites were randomized to FI or standard of care. At FI test sites, HIV+ persons received coupons ($125) redeemable if care visit occurred within 3 months (M). At FI care sites, patients (Pts) on ART could earn $70 gift card per quarter with VS. Lab data reported to HIV Surveillance were used for primary site-level outcomes: for L2C, CD4 or VL within 3M of HIV+ test; for VS, VL<400 copies/ml in engaged Pts (≥2 visits in last 15 M); for continuity in care, CD4 or VL in 4 of prior 5 quarters. FI sites reported numbers of eligible Pts, coupons, and gift cards dispensed. GEE were used to compare FI and SOC outcomes (Figure).

Results: 1,346 HIV+ PTS (443 BNY/903 DC) were included in evaluation of L2C at 15 hospitals and 19 community sites: In BNY/DC, respectively, 66%/76% were men, 35%/49% MSM, 50%/70% Black, 46%/10% Hispanic; 20% <25 years in both cities. On average 15,780 Pts were in care (8,927 BNY/6,853 DC) at 17 hospitals and 20 community sites: 57%/74% were men, 19%/48% MSM, 47%/72% Black and 48%/6% Hispanic in BNY/DC. For L2C, 1,061 coupons (238 BNY/823 DC) were dispensed and 194 (82%)/644(78%) redeemed in BNY/DC. For VS, 9,641 Pts (5,275 BNY/4,366 DC) were potentially eligible for gift cards, 84% of 49,650 visits qualified for cards (81% BNY/87% DC) and 39,359 gift cards were dispensed (23,265 BNY/16,094 DC).

For L2C, FI did not significantly increase overall L2C above SOC (OR: 1.05, 95%CI: 0.69, 1.58, p0.83) and no effect was noted in subsets of sites. For VS, while FI did not significantly increase VS overall (3.9%, CI: −3.5%, 11.2%, p0.3), substantial increases were noted at hospital clinics (4.9%, CI: 0.9%, 8.9%, p0.02), smaller sites (≤185 patients in care) (9.6%, CI:1.2%,17.9%, p0.03), sites with lower VS at baseline (≤65%) (10.4%, CI: 2.0%,18.7%, p0.01) and at peak of intervention (5.5%, CI:0.6%,10.5%, p0.03). No difference was noted by city for L2C or VS. FI increased continuity of care by 8% overall (CI: 2.1%, 13.9%, p0.008), and at community clinics, smaller sites, and sites with higher baseline VS.

Endpoints	Effect of Financial Incentives compared to standard of care (95% confidence Intervals)	p-value
Linkage to Care (L2C) (Among newly diagnosed HIV+ or out of care HIV re-tester)	Increase in odds of linkage to care	
Linked to care within 3 months: N = 34 sites	1.05 (0.69, 1.58)	0.83
Viral Suppression (VS) (VL<400 copies/mL among patients in care at a site)	Increase in proportion of virally suppressed patients	
All patients in care: N = 37 sites	3.9% (-3.5%, 11.2%)	0.30
Peak of intervention (Q4 2012)	5.5% (0.6%, 10.5%)	0.031
Subgroups:		
Smaller clinics* (≤185 HIV-infected patients): N = 19	9.6% (1.2%, 17.9%)	0.025
Larger clinics*: N = 18	5.4% (-1.3%, 12.1%	0.11
Lower baseline VS (≤65% VS): N = 19	10.4% (2.0%, 18.7%)	0.015
Higher baseline VS: N = 18	2.4% (-5.9%, 10.8%)	0.57
Hospital-based clinics: N = 17	4.9% (0.9%, 8.9%)	0.016
Community clinics: N = 20	2.3% (-7.0%, 11.6%)	0.63
Continuity in care (Clinic visits in 4 of prior 5 quarters among patients in care)	Increase in proportion of patients with continuity of care	
All patients in care: N = 37 sites	8.0% (2.1%, 13.9%)	0.008
Peak of intervention (Q4 2012)	7.9% (2.5%, 13.4%)	0.006
Subgroups		
Smaller clinics* (≤185 HIV-infected patients): N = 19	23.1% (14.8%, 31.3%)	<0.001
Larger clinics*: N = 18	5.6% (-1.1%, 12.3%)	0.10
Lower baseline VS (≤65% HIV-infected VS): N = 19	8.1% (-3.2%, 19.5%)	0.16
Higher baseline VS: N = 18	8.7% (2.3%, 15.0%)	0.007
Hospital-based clinics: N = 17	6.5% (0.2%, 12.7%)	0.042
Community clinics: N = 20	10.0% (1.7%, 18.3%)	0.019

*size of clinic based on median number of patients engaged in care at baseline

Conclusions: FI did not increase L2C. However, use of FI for VS showed promising effectiveness for sites with fewer patients, lower VS and hospital-based clinics and offers potential for treatment as prevention.

30 Medical Male Circumcision of HIV-Infected Men Reduces Long-Term Penile HIV Shedding

Jordyn L. Manucci[1]; Godfrey Kigozi[3]; Mary K. Grabowski[2]; David Serwadda[3]; Ronald H. Gray[2]; Maria J. Wawer[2]; Fred Nalugoda[3]; Andrew D. Redd[4]; Thomas C. Quinn[4]; Aaron A. Tobian[1]

[1]Johns Hopkins University School of Medicine, Baltimore, MD, US; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [3]Makerere University College of Health Sciences, Kampala, Uganda; [4]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, DC, US

Background: Medical male circumcision (MMC) for HIV prevention in uninfected men is increasing. In HIV-infected men, MMC is safe and reduces genital ulceration and HPV acquisition. MMC of HIV+ men reduced male-to-female transmission in observational studies, but in a randomized trial MMC was associated with increased HIV transmission to female partners if couples resumed intercourse prior to wound-healing. HIV shedding from MMC wounds is detectable in 39% of HIV+ men during the wound-healing (weeks 1-4), but decreased to 2.6% at six weeks post-MMC. We assessed penile HIV shedding before and three months after MMC among HIV-infected men in Rakai, Uganda to determine whether low HIV shedding is sustained and might reduce female HIV exposures.

Methods: HIV shedding was evaluated among 160 self-reported antiretroviral therapy (ART)-naïve HIV-infected men using a lavage of 5 mL of phosphate buffered saline (PBS, pH=7.2) at the coronal sulcus immediately prior to MMC and at MMC three month postoperatively. Penile HIV-1 RNA viral levels (VL) were determined by reverse transcriptase polymerase-chain-reaction (RT-PCR) assay (Abbott Laboratories. Abbott Park, IL). Matched odds ratios (MOR) of detectable HIV-1 post-MMC relative to pre-MMC were estimated using conditional logistic regression. Differences in amount of HIV shedding (log_{10} copies/mL of lavage fluid) among those with detectable lavage were assessed using Wilcoxon-Mann-Whitney tests.

Results: HIV shedding among ART-naive men was detected in 8.8% (n=14/160) of men prior to surgery and in 1.9% (n=3/160) 3 months post-MMC (MOR=0.15, 95%CI=0.35-0.68, p=0.01). Among men with detectable HIV shedding at enrollment, the median HIV VL was 2.47 log_{10}/ml (IQR=2.19-3.10) compared to 2.20 log_{10}/ml (IQR=2.06-2.23) at month three post-MMC (p=0.20). In a sensitivity analysis of men with CD4 count >350 cells/uL, HIV shedding was detected in 7.2% (n=8/106) of men prior to surgery and in 1.9% (n=2/106) 3 months post-MMC (MOR=0.25, 95%CI=0.05-1.17, p=0.08).

Conclusions: Detectable penile HIV shedding is reduced by 85% three months after MMC in ART-naïve HIV+ men. The data suggest that MMC in HIV-infected men may reduce HIV exposure and potentially transmission to uninfected female partners after wound healing.

Room 613

10:00 am – 12:00 pm

Prevention, Diagnosis, and Treatment of Pediatric HIV Infection

31LB PROMISE: Efficacy and Safety of 2 Strategies to Prevent Perinatal HIV Transmission

Mary Glenn Fowler[1]; Min Qin[2]; Susan A. Fiscus[3]; Judith S. Currier[4]; Bonus Makanani[5]; Francis Martinson[6]; Tsungai Chipato[7]; Renee Browning[8]; David Shapiro[2]; Lynne Mofenson[9]
On Behalf of the IMPAACT PROMISE Team

[1]Johns Hopkins University School of Medicine/Makerere University–Johns Hopkins University Research Collaboration, Baltimore, MD, US; [2]Harvard School of Public Health, Center for Biostatistics in AIDS Research, Boston, MA, US; [3]University of North Carolina at Chapel Hill, Chapel Hill, NC, US; [4]University of California Los Angeles, Los Angeles, CA, US; [5]Univ of Malawi, Blantyre, Malawi; [6]University of North Carolina Project–Malawi, Lilongwe, Malawi; [7]Univ of Zimbabwe, Harare, Zimbabwe; [8]NIAID/NIH, Bethesda, MD, US; [9]National Institute of Child Health and Human Development, Bethesda, MD, US

Background: There are limited **c**linical trial data comparing the efficacy and safety of antepartum (AP) antiretroviral (ARV) regimens for prevention of mother-to-child transmission (PMTCT) in women with high CD4 counts.

Methods: PROMISE 1077BF/1077FF is an ongoing, prospective, open-label randomized trial being conducted in 14 sites in Africa and India among HIV+ pregnant and postpartum women with high CD4 counts. The trial has 3 randomized components, assessing the maternal and infant efficacy and safety of ARV PMTCT strategies during 3 periods: pregnancy through 14 days postpartum; breastfeeding; and after MTCT risk is over. The AP component compared a zidovudine (ZDV)-based regimen (**Arm A:** AP ZDV + single-dose nevirapine (NVP) at delivery + tenofovir (TDF)/emtricitabine (FTC) tail) and two triple ARV regimens (**Arm B:** ZDV-lamivudine (3TC) + lopinavir/ritonavir (LPV-r); **Arm C:** TDF/FTC + LPV-r). Efficacy analyses using infant Roche 1.5 PCR, compared MTCT in Arm A to the pooled triple ARV arms. Safety analyses compared all 3 arms. Since Arm C was only open to all women in protocol Version 3 (V3), comparisons of Arms A and B included all women, but comparisons with Arm C only included those randomized under V3.

Results: On 11/4/14, the Data Safety Monitoring Board recommended release of interim AP data through 14 days post delivery. As of 9/10/14, 3529 pregnant women had enrolled, including 1230 women in V3, and 3234 live births had occurred. Baseline median maternal age was 26 years; 97% were black African; median enrollment gestational age was 26 weeks; 97% were WHO Clinical Stage I; median CD4 was 530 cells/uL and 58% had CD4 ≥500 cells/uL. The Table shows significantly reduced MTCT with triple ARVs during pregnancy compared to Arm A. There were no maternal deaths. We found significantly higher rates of Grade ≥2 maternal chemistry events and moderate adverse pregnancy outcomes with either triple ARV arm compared to Arm A; but no significant differences in very preterm delivery (VPTD) <34 weeks, very low birth weight (VLBW) < 1500 g, or early neonatal death between Arm A and either triple ARV arm. However, among 1229 enrollees in V3, ZDV/3TC+ LPV-r was associated with significantly lower risk of neonatal death or VPTD than TDF/FTC + LPV-r.

OUTCOME (N in analyses)	Arm A ZDV/NVP	Arm B ZDV/3TC/LPV-r	Arm C TRV/LPV-r	P Value*

#1077BF and 1077FF refer to the breastfeeding (1077BF) and formula feeding (1077FF) protocol versions
*Fisher's Exact Test P-value (outcomes with P>0.05 for all 3 pairwise comparisons are not shown)
**MTCT difference (group sequential repeated confidence interval)
[a] Any ≥grade 2 Hem/Chemistry adverse event (AE) or ≥grade 3 Sign/Symptom or Pregnancy related diagnosis
[b] Low birth weight (LBW) <2500 g; Preterm delivery (PTD) <37 wks; Stillbirth; Birth defect
[c] Very low birth weight (VLBW) <1500 g; Very preterm delivery (VPTD) <34 wks; Stillbirth; Major birth defect.

Conclusions: These results provide the first clinical trial evidence to support the current WHO PMTCT recommendations for use of triple ARVs during pregnancy. The safety findings require further study.

32 Most Breastfeeding Women With High Viral Load Are Still Undiagnosed in Sub-Saharan Africa

David Maman[1]; Helena Huerga[1]; Irene Mukui[4]; Benson Chilima[2]; Beatrice Kirubi[5]; Gilles Van Cutsem[6]; Charles Masiku[7]; Elisabeth Szumilin[8]; Thomas Ellman[3]; Jean-François Etard[1]

[1]Epicentre/Médecins Sans Frontières, Paris, France; [2]3. Ministry of Health, Lilongwe, Malawi; [3]Medecins Sans Frontières, Cape Town, South Africa; [4]National AIDS and STDs Control Program, Nairobi, Kenya; [5]Médecins Sans Frontières, Nairobi, Kenya; [6]Médecins Sans Frontières, Cape Town, South Africa; [7]Médecins Sans Frontières, Lilongwe, Malawi; [8]Médecins Sans Frontières, Paris, France

Background: No study has assessed the proportion of HIV-positive pregnant or breastfeeding (PBF) women virally suppressed at population level. Furthermore, critical data assessing the cascade of care among PBF women are needed to inform program policy. We used data from three population surveys to assess these key indicators.

Methods: Three household based surveys of individuals age 15 to 59 took place between September 2012 and November 2013 in Ndhiwa (Kenya), Chiradzulu (Malawi) and Mbolongwane/Eshowe (South Africa). Following consent, all individuals were interviewed and tested for HIV. Women reported their pregnancy and breastfeeding status and the result of their last HIV test. All individuals found HIV-positive were tested for viral load and CD4, regardless of the ART status. At the time of the survey, PMTCT option A was implemented in Kenya, B+ in Malawi and B in South Africa. Infection during PBF was defined as a positive-HIV test among a PBF woman who was unaware of her status and reported a negative HIV test during Ante Natal Care (ANC).

Results: Among the 21,782 individuals eligible, 12,461 were women and of them, 11,550(92.7%) were included in the surveys. More women were PBF in Kenya (37.8%, 1,413/3,760) and in Malawi (33.8%, 1,444/4,275) than in South Africa (12.5%, 439/3,515). Among them, HIV prevalence ranged from 13.4% in Malawi to 22.2% in Kenya and 23.0% in South Africa. The proportion of PBF women with viral load<1,000copies/ml was higher in South Africa (63.4%;95%CI 65.5-72.3) and Malawi (72.3%; 95%CI 65.5-78.2) compare to Kenya (27.3%; 95%CI 22.5-72.3). Of the breastfeeding women with viral load >1,000copies/mL, 58.6% (95%CI 52.0-65.0) were not diagnosed for HIV at the time of the survey. This proportion was similar across sites (p=0.16).

A total of 103(4.1%) breastfeeding women were infected during pregnancy or breastfeeding. This proportion was higher in Kenya (6.5%) than in South Africa (4.3%) and Malawi (1.9%). These new infections accounted for 37.5% (95%CI 31.5-44.4) of the HIV-positive breastfeeding women with viral load>1,000 copies/ml.

Conclusions: Viral suppression at population level among PBF women ranged from 27 to 72%. Our analysis showed that the majority of HIV+ PBF women with viral load>1,000cp/mL were undiagnosed which could be partly due to infection after HIV testing at ANC. To identify those women and to prevent transmission or at least to ensure early diagnosis of their infants, repeated HIV-testing should be implemented until the end of breastfeeding.

33 Delayed HIV Detection in Infants Exposed to ARV Prophylaxis During Breastfeeding

Caroline C. King[1]; Julie A. Nelson[2]; Carrie Ziemniak[3]; Michael G. Hudgens[2]; Gerald Tegha[4]; Charles S. Chasela[5]; Denise J. Jamieson[1]; Deborah Persaud[3]; Charles M. van der Horst[2]; Athena P. Kourtis[1]

[1]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US; [2]University of North Carolina at Chapel Hill, Chapel Hill, NC, US; [3]Johns Hopkins University, Baltimore, MD, US; [4]UNC Project, Lilongwe, Malawi; [5]University of Witwatersrand, Johannesburg, South Africa

Background: We reported on the effectiveness of 28 weeks of infant nevirapine or maternal antiretrovirals in preventing HIV transmission during breastfeeding from a randomized trial of 2369 mother-infant pairs: the Breastfeeding, Antiretrovirals and Nutrition (BAN) study. After counseling on breastfeeding cessation and stopping the antiretroviral intervention, 28 infections were detected from 29 to 48 weeks: 13 on infant nevirapine arm (n=852), 9 on maternal ARV arm (n=849), and 6 on control arm (n=668). To determine whether the infections detected after 28 weeks occurred during the breastfeeding and antiretroviral intervention phase but had delayed detection on the antiretroviral arms, we performed ultrasensitive HIV testing on stored infant PBMC specimens.

Methods: Infants in the BAN study were tested for HIV DNA via the Roche Amplicor 1.5 assay on whole blood at birth, 2, 12, 28 and 48 weeks, and, to narrow the window of transmission, dried blood spots from intervening visits were tested. For this substudy, ultrasensitive (droplet digital PCR) HIV testing was performed on infants with HIV infections first detected after 28 weeks and stored PBMC specimens at 24 weeks (n=9).

Results: All three infants tested on the infant nevirapine arm had detectable HIV DNA at 24 weeks, compared to 2 of 4 infants on the maternal ARV and 1 of 2 on the control arms. For infants with detectable HIV at 24 weeks, the median delay in detection between the ultrasensitive and routine assays was 18.3 weeks for the nevirapine arm, 15.4 weeks for the maternal arm, and 9.4 weeks for the control arm. There were no significant differences in maternal viral load or reported antiretroviral adherence between arms for the 9 infants with ultrasensitive testing. None of the 3 infants on the nevirapine arm harbored de novo nevirapine resistance mutations.

Ultrasensitive HIV DNA assay results on 9 infants who first tested HIV-positive by sensitive assay after reported breastfeeding cessation and stopping the postnatal ARV intervention by 28 weeks.

ID	Arm	Last breastfed (age in days)	BAN HIV-negative results, starting at 12-week visit* (age in days)	BAN first HIV-positive result* (age in days)	Ultrasensitive HIV DNA assay results on PBMC at 24-week visit. For detectable HIV DNA, pol copy per 106 PBMCs	Resistance testing of mother and infant (at 48-week visit)
1	Infant NVP	203	84, 203, 232, 260, 263	302	Detectable at 179 days 6.1 copies	No mutations
2	Infant NVP	196	85, 196, 254	321	Detectable at 167 days 4.1 copies 5.1 copies	K103N†
3	Infant NVP	199	85, 199, 227, 255	299	Detectable at 171 days 20.1 copies	No mutations
4	Maternal ARV	196	84, 196, 224, 252, 293	321	Undetectable at 167 days	No mutations
5	Maternal ARV	204	85, 204, 262	303	Detectable at 176 days 23.5 copies 15.4 copies	No mutations
6	Maternal ARV	197	84, 197	230	Undetectable at 169 days	No mutations
7	Maternal ARV	168	84, 196, 224	257	Detectable at 168 days 2.1 copies 7.5 copies	No mutations
8	Control	202	90, 202	240	Detectable at 174 days 20.0 copies 32.7 copies	No mutations
9	Control	172	88, 196, 225, 256	293	Undetectable at 168 days	No mutations

* Infant HIV testing during the BAN Study follow-up was done on whole blood collected at birth, 2, 12, 28 and 48 weeks with a qualitative Roche Amplicor 1.5 DNA PCR assay (Roche Molecular Systems, Pleasanton, CA, USA). For positive infants, the window of HIV transmission was later narrowed by testing dried blood-spot specimens from interim visits for HIV DNA by Roche DNA assay or RNA using Gen-Probe Aptima HIV-1 assay.

† Mutation seen in mother and infant.

Conclusions: Using an ultrasensitive assay, extremely low HIV DNA concentrations were detected in 6 of 9 (66%) infants up to 22 weeks earlier than by standard testing**.** The prolonged inability to detect HIV DNA of routine sensitive assays in the context of postnatal ARV prophylaxis suggests that early antiretrovirals restrict HIV replication sufficiently to lead to missed diagnosis. Late detection of HIV infections also suggests that repeated virologic testing beyond the WHO recommendation of 6 weeks after breastfeeding cessation is warranted. Ultrasensitive testing may allow for earlier antiretroviral treatment, which might modify establishment of HIV reservoirs.

34 Evaluation of the Alere q for Point-of-Care Early Infant HIV Diagnosis in South Africa

Nei-Yuan Hsiao[1]; Max Kroon[2]; Lorna Dunning[2]; Landon Myer[2]

[1]University of Cape Town, Cape Town, South Africa; [2]University of Cape Town, Cape Town, South Africa

Background: New point-of-care (POC) HIV molecular diagnostic tools could fundamentally alter early infant HIV diagnosis (EID) and management in resource-limited settings by reducing the time to initiation of antiretroviral therapy and promoting retention in care. However few technologies have been independently evaluated and data on new technologies are urgently required.

Methods: We investigated the analytic performance of the Alere q HIV1/2 POC assay in the laboratory setting by comparing the result with the local standard-of-care (SOC), Roche CAP/CTM HIV-1 qualitative PCR. Testing was conducted on routinely collected EID samples received at the public sector reference lab in Cape Town, South Africa between November 2013 and September 2014. Cycle threshold (CT) values from the Roche systm were used as measures of relative quantification.

Results: A total of 1065 HIV-exposed infants (median age, 47 days) undergoing SOC testing with final infant status available were included in the study. The first Alere q test resulted in an error for 60 samples (6%) but 70% of all errors were resolved with a second Alere q test. The performance of Alere q is shown in Table 1. Excluding errors, overall specificity was 100% (lower bound of 95% confidence interval [CI], 99.5%) and sensitivity was 96.8% (95% CI, 93.2%-98.8%). False negative samples had a median CT value of 32.8 on the SOC assay, higher than both the true positives (median CT, 24.2; p<0.001) and errors (median CT, 21.0; p<0.001). When analysis was restricted to specimens from newborns tested at <3 days of age, specificity remained high (100%) but sensitivity decreased to 91.6%.

		Roche CAP/CTM HIV-1 qualitative PCR		
		Positive	*Negative*	*Total*
Alere q POC PCR (first test)	*Positive*	185	0	185
	Negative	6	814	820
	Error	11	49	60
	Total	202	863	1065

Table 1. Performance of Alere q point-of-care test compared to Roche CAP/CTM HIV-1 qualitative PCR for early infant diagnosis, based on 1065 children with final infant HIV status available.

Conclusions: These results demonstrate good performance characteristics of this POC assay used for EID in the laboratory setting. While POC testing for EID may have particular utility in the context of birth testing within delivery facilities, the lower sensitivity of tests conducted within 3 days of birth require attention. Higher CT values were observed for false negative results, possibly due to lower levels of circulating virus during early infection. Further research is required to determine whether similar results can be achieved when this technology is implemented in clinical care settings, including for in birth testing.

35 Early ART and Sustained Virological Suppression Limits HIV Proviral DNA Reservoir: CHER Evidence

Helen A. Payne[1]; Sarah Watters[1]; Marvin Hsaio[2]; Robin Callard[1]; Abdel Babiker[3]; Mark F. Cotton[4]; Kennedy Otwombe[5]; Avy Violari[5]; Diana M. Gibb[3]; Nigel J. Klein[1]

[1]University College London, London, United Kingdom; [2]University of Cape Town, Cape Town, South Africa; [3]MRC Clinical Trials Unit at University College London, London, United Kingdom; [4]Stellenbosch University, Cape Town, South Africa; [5]University of Witswatersrand, Johannesburg, South Africa

Background: Improved understanding of HIV-1 proviral DNA latent reservoir formation and impact of ART-strategies on reservoir size can inform treatment strategies in paediatric HIV.

Methods: HIV-1 proviral DNA was measured from a substudy of 118 children from the Children with HIV Early Antiretroviral Therapy (CHER) trial where HIV-infected infants <12 weeks with CD4% ≥25% were randomised to early limited ART for 40 or 96 weeks or deferred ART. For Infants on deferred ART or following ART interruption after 40/96 weeks ART was started/re-started for clinical progression (CDC severe stage B/C disease) or CD4% <20%. HIV-1 proviral DNA was measured by quantitative PCR using DNA extracted from 384 cryopreserved PBMC samples taken 12-weekly from 40 to 252 weeks after a minimum of 24 weeks of ART. The effects on proviral DNA decline of early versus deferred ART and ART-interruption were investigated. Predictive factors for reservoir decline were explored including ART duration, enrolment CD4 and CD4 at 96 weeks, HIV serostatus and quantitative HIV-antibody at 84 weeks, baseline CMV viraemia, immunological phenotypes, enrolment viral load, viral load 9-12 months prior to proviral DNA measurement and total weeks continuous suppression below 400 copies/ml. The profiles of 5 children with undetectable proviral DNA measurements were also described.

Results: After a minimum 24 weeks of ART, 73 children starting early ART showed a trend towards less HIV-1 proviral DNA compared with 45 children on deferred ART: median 27 [IQR 8 – 51] versus 100 [48 – 202] copies of provirus per 10^5 PBMCs, p=0.08). Overall, reduced reservoir size and probability of developing an undetectable reservoir were strongly associated with earlier ART-initiation and longer continuous virological suppression (p-values all <0.0001). However patterns of decline varied despite continuous ART and apparent virological suppression. ART-interruption only modestly increased levels of proviral DNA (p=0.03). HIV serostatus did not correlate with reservoir size (p=0.92) but higher CMV DNA levels at enrolment were associated with an increased HIV reservoir (p=0.02). Four children with undetectable proviral DNA underwent ART-interruption as per CHER randomisation and exhibited HIV-1 viral resurgence.

Conclusions: These findings inform the interplay between clinical, immunological or virological factors involved in reservoir dynamics, and support the view that early-initiation of ART and sustained virological suppression are key to reservoir reduction.

36 Long-Term Outcomes of HIV-Infected Children Initiating NVP vs LPV/r-Based Treatment

Linda Barlow-Mosha[1]; Konstantia Angelidou[2]; Moherndran Archary[8]; Avy Violari[7]; Jane Lindsey[2]; Lynne Mofenson[3]; Patrick Jean-Philipe[5]; Paul E Palumbo[4]; Benjamin Chi[6]
On behalf of the IMPAACT P1060 Protocol Team

[1]Makerere University–Johns Hopkins University Research Collaboration, Kampala, Uganda; [2]Harvard School of Public Health, Center for Biostatistics in AIDS Research, Boston, MA, US; [3]National Institutes of Health, Bethesda, MD, US; [4]Geisel School of Medicine at Dartmouth, Lebanon, NH, US; [5]Henry M. Jackson Foundation for the Advancement of Military Medicine, Rockville, MD, US; [6]University of North Carolina at Chapel Hill, Chapel Hill, NC, US; [7]University of Witswatersrand, Johannesburg, South Africa; [8]University of KwaZulu-Natal, Durban, South Africa; [9]IMPAACT, SilverSpring, MD, US

Background: IMPAACT P1060 demonstrated short-term superiority of lopinavir/ritonavir (LPV/r)-based ART over nevirapine (NVP) for the primary endpoint (stopping randomized treatment, virologic failure [VF] or death by 24 weeks) in HIV-infected children regardless of NVP exposure at birth. In contrast, those on NVP had marginally superior improvements in CD4% and growth (weight and height z-scores). Longer-term outcomes are presented.

Methods: HIV-infected ART-eligible infants and children (2m - 3y) from 6 African countries and India enrolled into 2 cohorts based on prior NVP exposure (PrNVP) and were randomized to initiate NVP or LPV/r (with zidovudine and lamivudine). The study DSMB recommended closing enrollment and unblinding cohorts with PrNVP (2009) and no PrNVP (2010) due to superiority of the LPV/r arm for the primary endpoint. Participants could switch regimens and continue in observational follow-up. Randomized and observational data were combined in intent-to-treat (ITT) analyses to investigate long-term trends in VF and death (Cox proportional hazards models) and CD4% and growth (generalized

estimating equations). Additional analyses were performed using marginal structural models (MSM) to account for treatment switching and censoring. Models were adjusted for demographics and HIV disease status at entry.

Results: 229 participants were randomized to NVP and 222 to LPV/r based ART. As of January 2014, 75% were still in follow-up (median follow-up 4.6 years [IQR: 3.7-5.7]). From their original randomization, 48% were still on NVP while 81% were still on LPV/r. Participants in the NVP arm had significantly shorter time to VF (adjusted hazard ratio [aHR]: 1.91, 95%CI: 1.37-2.65) but not death (aHR: 1.64, 95%CI: 0.72-3.75). Mean CD4% and weight z-scores were higher in the NVP arm at 1 year, by 1.5% and 0.23 respectively ($p<0.05$), while height z-scores were not significantly higher by 0.15 ($p=0.10$). By the second year of follow-up, differences were no longer statistically significant. Similar trends were observed in MSM models for all outcomes.

Conclusions: Long-term virologic suppression was superior in children on LPV/r-based ART compared to NVP-based regimens. Early modest gains in CD4% and growth associated with NVP were no longer statistically significant beyond 1 year after ART initiation. These findings further support the current WHO recommendation for LPV/r-based ART as first line therapy for HIV-infected children aged < 3 years.

37 Structural Cardiovascular Changes Are Reversible in HIV-Infected Children in Zambia and Uganda.

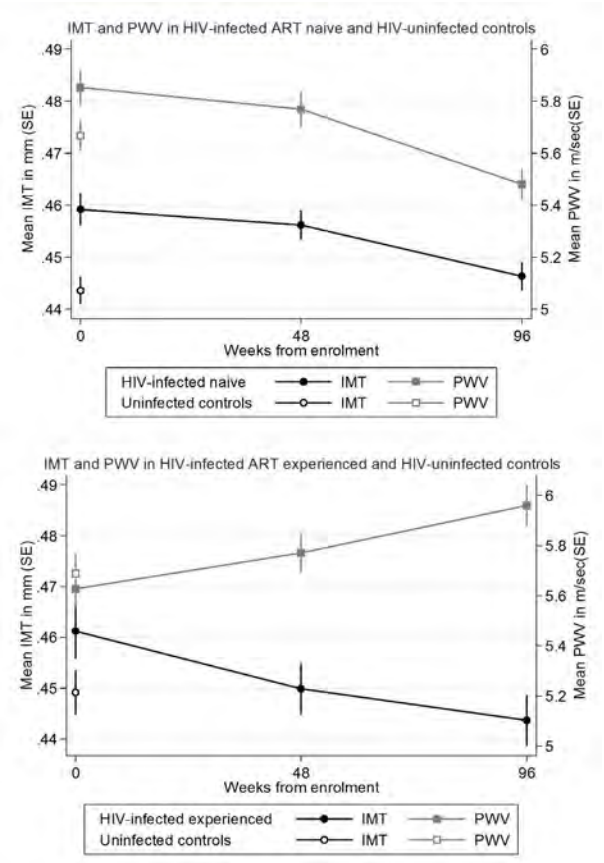
Julia M. Kenny[1]; Adrian Cook[1]; Grace Mirembe[2]; Dorica Masaku[3]; Priscilla Wavamunno[2]; Florence Odongo[2]; Alicja Rapala[1]; John Deanfield[1]; Diana M. Gibb[1]; Nigel J. Klein[1]

[1]University College London, London, United Kingdom; [2]Joint Clinical Research Centre, Kampala, Uganda; [3]University Teaching Hospital, Lusaka, Zambia

Background: Carotid intimal medial thickness (IMT) and pulse wave velocity (PWV), as measures of cardiovascular structure/function, are impaired in HIV-infected children in high-income countries. Few longitudinal data are available: none come from Africa where 90% HIV-infected children live.

Methods: ART-naïve and ART-experienced (on d4T+3TC+NNRTI for >2years, virologically suppressed at enrolment) HIV-infected children had IMT and PWV measured at baseline, 48 and 96 weeks within the CHAPAS-3 trial which evaluated d4T vs ZDV vs ABC-based first-line ART in Uganda/Zambia. Age-matched HIV-uninfected controls had a single assessment. Baseline differences between ART-naïve/experienced children vs controls, and longitudinal changes in HIV-infected children were compared using two-sample and paired t-tests respectively.

Results: In 208 ART-naïve children with median age 2.9y (IQR 1.7–4.4), median CD4% 18% (11-23) and 209 HIV-uninfected controls median age 3.0y (2.1–4.1), mean(sd) cIMT was 0.46(0.04) v 0.44(0.04)mm respectively ($p=0.0001$); PWV was 5.85(0.8) vs 5.67(0.74)m/sec respectively ($p=0.04$). Among 74 ART-experienced children on ART for mean 3.7y with median age 6.9y (5.9–8.50, median CD4% 33% (27-39) and 75 uninfected controls with median age 6.7y (5.6-8.6), mean(sd) cIMT was 0.46(0.05) vs 0.45(0.04)mm respectively ($p=0.09$); PWV was 5.63(0.61) vs 5.69(0.69)m/s respectively ($p=0.57$). In ART naïve children IMT and PWV significantly decreased from baseline (ART initiation) to week 96 mean(sd) cIMT -0.02(0.04)mm ($p=0.0001$), PWV -0.38(0.83)m/s ($p<0.0001$). In contrast whereas cIMT had significantly reduced by mean -0.2(0.06)mm ($p=0.01$) at week 96 in the ART experienced group PWV increased by 0.35(0.63)m/s ($p<0.0001$). There was no evidence that the changes differed by randomisation ART in either group ($p=0.6$).



Graph to show changes in IMT and PWV over 96 weeks in ART naive and ART experienced children with baseline data from age-matached HIV uninfected controls.

Conclusions: In this large study of arterial structural and function in HIV-infected children in Africa, ART-naïve HIV-infected children had significantly poorer IMT and PWV compared to age-matched controls but significant improvement seen after 96 weeks of ART. After a mean 3.7 years on ART, HIV-infected children had cIMT and PWV comparable to uninfected age-matched controls. IMT continued to improve after a further 96 weeks on ART. ART can reverse some of the structural/functional changes caused by HIV, strengthening the argument for early diagnosis and treatment of HIV-infected infants and children.

38LB ART With Weekends Off Is Noninferior to Continuous ART in Young People on EFV+2NRTI

Karina M. Butler
On behalf of the BREATHER Trial Team
Our Lady's Children's Hospital, Dublin, Ireland

Background: For HIV-1 infected young people (YP) facing lifelong ART, short cycle therapy (SCT) with long-acting agents offers the potential for drug-free weekends, less toxicity and better adherence, as well as cost savings.

Methods: BREATHER is a randomised, non-inferiority trial in Europe, Thailand, Uganda, Argentina & US. YP (>8, ≤24 yrs) on efavirenz (EFV)+2NRTIs and HIV-RNA (VL)<50c/ml for >12 months were randomised to continue daily ART (CT) or change to SCT (5 days on; 2 days off ART). Followup was for minimum 48 weeks, with 0, 4, 12, then 12 weekly visits. The primary outcome was the difference between arms in proportion with VL>50c/ml (confirmed) by 48 weeks, estimated using Kaplan-Meier method (12% non-inferiority margin) adjusted for region and age.

Results: 199 YP (11 countries) were randomised; 99 SCT, 100 CT and followed for median 86 weeks: 53% male, median age 14yrs (21% ≥18yrs); 35% Uganda site; 56% black, 19% Asian; 21% Caucasian; median CD4% 34%; CD4 count 793 cells/mm^3. By week 48, only one YP on CT was lost to followup. The SCT arm had 27% decreased drug exposure as measured by adherence questionnaire and a MEMs substudy showing median cap openings/week of 5 SCT vs 7 CT. By 48 weeks, 6 SCT vs 7 CT had confirmed VL>50c/ml; difference (90% CI) -1.2% (-7.3, 4.9); 2 SCT vs 4 CT had confirmed VL>400c/ml; difference 2% (-6, 2.0). All 6 SCT with VL>50c/ml resumed daily ART; 5/6 resuppressed, 3 on same regimen, 2 with switch; 2 others on SCT resumed daily ART for other reasons. Overall, 4 SCT vs 11 CT (p=0.1) changed ART regimen: 8 for toxicity, 4 simplification, 2 compliance and 1 VL failure. 7 YP (2 SCT, 5 CT) had major NNRTI mutations at VL failure; 2 (1 SCT, 1 CT) had M184V. 2 YP had new CDC B events (1 SCT, 1 CT). There were no significant differences in toxicity between SCT and CT: grade 3/4 AEs (8 vs 12), ART-related AEs (2 vs 8), SAEs (7 vs 6). At week 48, there was no evidence that SCT led to increased inflammation using an extensive panel of markers. YP expressed preference for SCT in a qualitative substudy and in pre- and post-trial questionnaires, particularly as it enabled weekend time with friends. 98% YP are in a 2-year followup extension of the trial.

Conclusions: Non-inferiority of VL suppression in YP on EFV-based firstline ART with VL<50c/ml was demonstrated for SCT vs CT, with similar resistance, safety and inflammatory marker profiles. Detailed evaluation of the immunological and virological impact of SCT is planned.

Session O-3 Oral Abstracts — Room 615

10:00 am – 12:00 pm

Cellular Dynamics, Sensing, and Viral Restriction

39 Envelope Trimer Numbers Required for Entry Steer HIV-1 Infectivity and Entry Kinetics

Oliver Brandenberg[2]; Carsten Magnus[2]; Peter Rusert[2]; Roland Regoes[1]; **Alexandra Trkola**[2]
[1]*ETH Zurich, Zurich, Switzerland;* [2]*University of Zurich, Zurich, Switzerland*

Background: The individual steps of the HIV entry process have been defined in detail. However, uncertainty prevails on the stoichiometric requirements of the entry process, namely the number of envelope trimers that need to be engaged to trigger membrane fusion. Here, we provide estimates of the HIV-1 entry stoichiometry utilizing a combined approach that incorporates experimental analyses and mathematical modeling.

Methods: To estimate the stoichiometry of entry (T) we analyzed pseudotyped virus stocks carrying mixed envelope trimers consisting of functional (wt) and dominant-negative mutant env, where a single dominant-negative env subunit incorporated into a trimer renders the trimer non-functional. Pseudovirus stocks expressing mixed trimers with different ratios of wt and dominant-negative env were produced in 293-T cells and virus infectivity determined by titration on TZM-bl reporter cells. Analysis of the data to derive estimates of T was performed using mathematical models we developed for this purpose. Virus entry kinetics were determined by a time-of-inhibitor addition experiment employing T-20 to stop virus infection of target cells at defined timepoints post-infection.

Results: Analysis of 11 divergent HIV-1 strains revealed that isolates differ in their requirements for trimer numbers during entry, with estimates ranging from 1 to 7 trimers and most isolates depending on 2 to 3 trimers to complete infection. Highlighting the biological relevance of our finding, a high entry stoichiometry proved to correlate with low virus strain infectivity and slow entry kinetics. This was confirmed studying the naturally occurring point mutation N160K in gp120 and by extensive analysis of mutant viruses lacking the V1V2 domain. In both cases changes in infectivity were reflected in different estimates of the entry stoichiometry compared to the matching wt envelopes.

Conclusions: While HIV can overcome partial envelope protein deficiencies by increasing the number of trimers involved in the entry process, this restricts infectivity to those virions that carry higher numbers of trimers, thereby reducing the overall infectivity of a virus population. Our data thus add an important concept to the growing body of information on molecular aspects of HIV entry and membrane fusion.

40 HIV-1 Accessory Protein Function: Evaluating VPU-Dependent Host Factor Degradation

Prashant Jain; Kevin Olivieri; Quy Nguyen; Paul De Jesus; Sumit Chanda
Sanford-Burnham Medical Research Institute, La Jolla, CA, US

Background: Cellular proteins called "restriction factors" are important in counteracting HIV-1 infection through cell intrinsic immune mechanisms. BST2 (Tetherin) is a cellular factor that prevents virion release by trapping HIV-1 on the plasma membrane. The HIV-1 accessory protein VPU is known to down-regulate BST2, thereby aiding in virion release. We hypothesize that VPU may target additional host factors to facilitate immune evasion. Here, we describe a 'High Content Imaging' based proteomic screen to identify host factors degraded by the HIV-1 VPU.

Methods: To identify novel host targets of VPU, 950 V5 tagged ISGs (Interferon Stimulated Genes), as well as VPU-Flag or a control LacZ-Flag were co-expressed in 293T cells. The cells were immunostained for V5 or Flag epitopes and imaged with Opera QEHS high content imaging microscope. Mean fluorescence intensity (MFI) for ISG-V5 was deduced in cells expressing either VPU-Flag or the LacZ-Flag. ISGs showing decreased MFI following VPU-Flag versus LacZ-Flag co-expression were considered as degraded by VPU.

Results: Following plate median normalization of fold change in V5 staining intensities, 10 host ISGs were identified as true hits for VPU dependent degradation. Confirmatory studies involving a secondary screen and immunoblot analysis of cell lysates confirmed the degradation of 6 ISGs identified in the primary screen. UBE2L6, an E2 ligase for ISG15 conjugation, was a primary hit and selected for downstream verification and functional analysis. Cross profiling ISG degradation following co-expression of HIV1 accessory proteins VPU, VIF and NEF, indicated a VPU specific degradation of UBE2L6. Importantly, we observed a significant and VPU dependent reduction in endogenous UBE2L6 as well as ISG15 conjugation in THP1 cells infected with HIV-1 VSVg wt or a VPU deficient HIV-1 VSVg. Our data indicates that HIV1 VPU modulates cellular ISG15 conjugation machinery by targeting the E2 ligase UBE2L6.

Conclusions: We describe a High Content imaging approach to identify novel host targets of HIV-1 VPU. Our results indicate that VPU targets multiple putative restriction factors for degradation. Elucidating the role of identified hits in counteracting HIV-1 infection would greatly enhance our understanding of VPU dependent enhancement of HIV-1 infection. Comprehensive understanding of virus dependent modulation of host immune machinery would significantly assist in developing effective anti-viral measures.

41 HIV-1 Adaptation to Humans Involved Interactions of Vpr With the DNA Damage Response

Oliver I. Fregoso; Michael Emerman

Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US

Background: The accessory protein Vpr is encoded by all extant primate lentiviruses and is important for viral replication *in vivo*. HIV-1 Vpr interacts with the host Cul4-DCAF1 ubiquitin ligase complex as well as the SLX4 complex of structure-specific nucleases, which have been implicated in the innate immune response. In addition, Vpr expression leads to G2 cell cycle arrest and activation of the DNA damage response after infection. We asked whether or not these functions of Vpr are related and what role adaptation of HIV-1 to humans played in shaping these interactions.

Methods: We cloned Vpr from a diverse array of primate lentiviruses. Through evolutionary analyses, we generated a phylogenetic framework of these Vpr isolates and tested them for their ability to interact with the human Cul4-DCAF1 complex and the human SLX4 complex by co-immunoprecipitation. We assayed for the ability of Vpr orthologs to activate the DNA damage response by immunofluorescence for DNA damage-associated foci and by cell-cycle analyses.

Results: We have identified that all Vpr orthologs are able to interact with the human Cul4-DCAF1 complex. Furthermore, we have found that a subset of these Vpr proteins can activate the DNA damage response in human cells. However, DNA damage induced by Vpr does not directly correlate with ability of Vpr to recruit the SLX4 complex. Instead, this function arose in select lentiviral lineages, including HIV-1 but not HIV-2.

Conclusions: The recruitment of Cul4-DCAF1 is a conserved ancestral function of Vpr and indicates that all Vpr orthologs have the potential to activate the DNA damage response in their hosts. As activation of the DNA damage response and SLX4 complex recruitment do not correlate, this indicates that Vpr activates host DNA damage response pathways through a still unknown mechanism. Moreover, our data suggests that recruitment of this complex occurred after the cross-species transmission of lentiviruses from chimpanzees to humans, and is therefore important for the adaptation of HIV-1 group M to humans.

42 The HIV-1 Protease Can Interact With RNA to Dramatically Enhance Its Activity

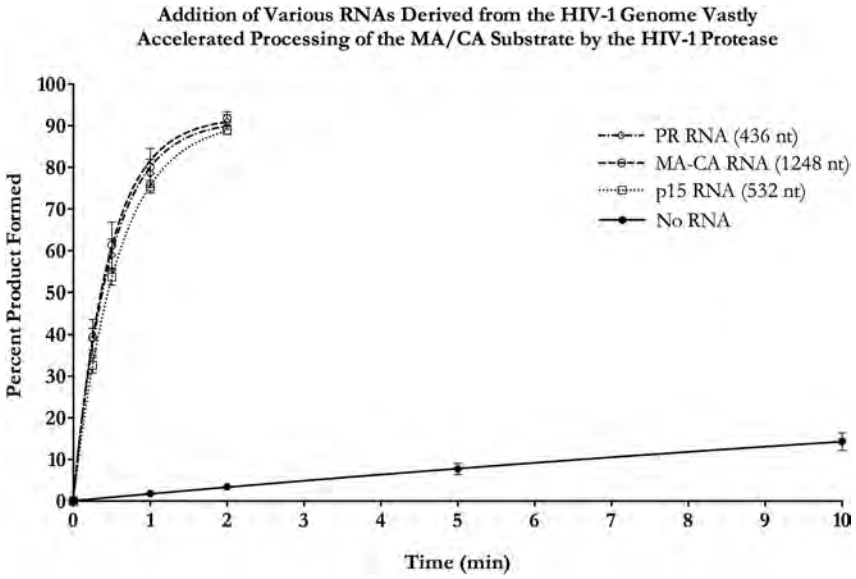
Marc Potempa[1]; Ellen Nalivaika[2]; Sook-Kyung Lee[1]; Celia A. Schiffer[2]; Ronald Swanstrom[1]

[1]*University of North Carolina, Chapel Hill, NC, US;* [2]*University of Massachusetts Medical School, Worcester, MA, US*

Background: In the maturation step of the HIV-1 lifecycle, the virus-encoded protease (PR) must process the structural polyprotein Gag to generate infectious virus particles. Previous reports found that cleavage of the p15NC maturation intermediate accelerates when RNA is present. Our studies have shown RNA-enhancement is substrate-independent. We hypothesize that enhancement results from an interaction between PR and RNA.

Methods: *In vitro* proteolysis reactions were performed +/- RNA with globular substrates derived from Gag or a 12-amino acid peptide. HIV PRs of multiple lineages were used to investigate whether RNA-enhancement is general to HIV. Alternative nucleic acids were also employed. Gel-shift assays were used to examine interactions between proteins and nucleic acids.

Results: Addition of RNA to two-substrate *in vitro* proteolysis reactions containing Gag derivatives p15NC and MA/CA accelerated cleavage of both substrates. In reactions with only MA/CA, the rate increased 80x (see figure). Cleavage of a peptide substrate, too small to interact with RNA and be simultaneously cleaved, was accelerated 20x. These data argue that RNA enhancement is substrate-independent. RNA enhanced the activity of Subtype B, C, and AE PRs; however, the HIV-2 PR was unaffected. Select short DNA oligonucleotides (~20 bases) capable of forming homomultimers could increase PR activity, but to a lesser degree than long, heteropolymeric RNA. The PR preferentially interacted with the multimeric forms of oligos in gel-shift assays, implicating the DNA complexes as necessary. Dimer stability is unaffected by RNA, since the tethered-dimer was equivalent to the wild-type PR in our assays. RNA lowered the K_m by 5-10x, and raised the V_{max} 2-5x.



Conclusions: RNA can directly interact with HIV-1 PRs *in vitro*, dramatically increasing their catalytic activity. This interaction likely relies on electrostatic forces, rather than sequence, since multimer formation was the principle determinant of effectiveness for DNA oligonucleotides. Mechanistically, RNA likely affects PR function post-dimerization, since RNA equivalently enhanced the wild type and tethered-dimer PRs. The differences in K_m and V_{max} show that RNA increases the PR's affinity for its substrate and its turnover capacity. These data raise the possibility that PR cleavage during assembly is regulated in part by the juxtaposition of the viral PR and virion-packaged RNA.

43 PQBP1 Is a Retrovirus-Specific Sensor Mediating cGAS/IRF3-Dependent Innate Responses

Sunnie M. Yoh[1]; Monika Schneider[1]; Stephen Soonthornvarcharin[1]; Rana Akleh[1]; Kevin Olivieri[1]; Paul De Jesus[1]; Chunhai Ruan[2]; Elisa de Castro[3]; Pedro Ruiz[1]; Adolfo Garcia-Sastre[3]
[1]Sanford-Burnham Medical Research Institute, La Jolla, CA, US; [2]University of Michigan, Ann Arbor, MI, US; [3]Icahn School of Medicine at Mount Sinai, New York, NY, US

Background: Infection of dendritic cells (DCs) by HIV-1 triggers an innate immune response that has been shown to be mediated through a cyclic GAMP synthase (cGAS)/IRF3-dependent pathway. We hypothesized that this pathway was activated by a cellular factor that recognizes a retrovirus-encoded molecular feature upstream of cGAS/IRF3. In an attempt to identify this proximal sensor of a HIV-1 pathogen-associated molecular pattern (PAMP), we performed a targeted RNAi screen utilizing primary human monocyte-derived DCs (MDDCs) and identified the protein PQBP1 as an innate immune sensor for HIV-1 DNA in myeloid cells.

Methods: We utilized human MDDCs to perform a sub-genomic RNAi screen of putative nucleic acid-binding proteins to identify cellular factors required for the innate response to HIV-1 infection. Screening "hits" were further assayed for their ability to directly associate with HIV-1 nucleic acids in infected MDDCs. PQBP1 was the only molecule found to be required for both innate signaling and that associated with HIV-1 nucleic acids. PQBP1 was subjected to extensive validation using reconstituted stable shRNA and CRISPR cell lines, measurement of cellular cGAMP levels, *in vivo* and *in vitro* DNA binding assays and characterization of protein interactions.

Results: Through our analysis, we demonstrated that PQBP1 directly binds to reverse transcribed HIV-1 DNA, and that it interacts with cGAS to initiate an IRF3-dependent innate response in myeloid cells. Further analysis revealed that PQBP1 associates with HIV-1 DNA through its C-terminus, but that it requires an intact WW-domain to associate with cGAS. Our study indicates that PQBP1 specifically recognizes a restricted set of retrovirally encoded DNA PAMPs, possibly originating from the secondary structure of RT intermediates.

Conclusions: The ability to recognize invariant microbial features, and not pathogen specific elements, such as DNA sequence, is the definition of a pattern recognition receptor (PRR), and our evidence suggests that PQBP1 falls into this category. Our study presents a molecular understanding of how HIV-1 is recognized by professional antigen presenting cells to trigger cell-autonomous antiviral responses to promote adaptive immunity. Identification of PQBP1 as a direct sensor of retroviral DNA provides an opportunity for development of pharmacological agonists that may potentially improve HIV vaccine efficacies.

44 Mucosal HIV-1 Transmission Specifically Selects for Type 1 Interferon-Resistant Viruses

Shilpa Iyer[1]; Frederic Bibollet-Ruche[1]; Christiana M. Shaw[1]; Weiyu Zhang[1]; Yingying Li[1]; Timothy Decker[1]; George M. Shaw[1]; Persephone Borrow[2]; Beatrice H. Hahn[1]
[1]University of Pennsylvania, Philadelphia, PA, US; [2]University of Oxford, London, United Kingdom

Background: Mucosally transmitted founder (TF) HIV-1 are more resistant to the antiviral effects of type 1 interferons (IFNs) than viruses that predominate during chronic infection. To determine whether IFN-resistant viruses are specifically selected for during HIV-1 transmission, we derived viral isolates by limiting dilution from both plasma and genital fluids of chronically infected transmission donors and examined their relative IFN resistance.

Methods: Plasma and cervicovaginal lavage (CVL) were collected from the donors of epidemiologically linked transmission pairs. Plasma or the non-cellular fraction of CVL samples were incubated with activated CD4+ T-cells to generate limiting-dilution isolates. Half genome sequences were analyzed to characterize the extent of genetic diversity. IFNα sensitivity of each isolate was analyzed by determining the IC50 in primary CD4+ T-cells.

Results: We first used plasma from patient CH212 to determine that 500-1000 vRNA copies were required to obtain limiting dilution isolates. The diversity among 18 CH212 isolates was 2.5%, comparable to that observed by SGS analysis of the plasma vRNA. We determined the IFNα sensitivity of each virus isolate. IC50 values ranged from 8 to 115 U/ml and were significantly lower than the IC50 value of the TF virus (240 U/ml) of the CH162 recipient. In an attempt to isolate IFNα-resistant viruses from the plasma, the limiting dilution isolation method was repeated in the presence of IFNα. The IFNα IC50 values of the 5 new isolates ranged from 155 to 225 U/ml, revealing that IFNα resistant viruses are present, but infrequent, in the donor plasma. We next obtained limiting-dilution isolates from plasma (n=10) and matching CVL (n=10) from donor CH492. The mean genetic diversity and the mean IFNα IC50 values were comparable between isolates derived from plasma and genital secretions. Interestingly, one CVL-derived isolate had a significantly higher IFNα IC50 value and was genetically most closely related to the single TF identified in the CH427 recipient.

Conclusions: Viruses circulating in plasma and sexual secretions of chronically infected individuals exhibit a wide range of IFN resistance, and are generally more IFN sensitive than TF viruses that establish de novo infections. However, some donor viruses exhibit elevated resistance to IFNα and seem to be those that are preferentially transmitted. Thus, IFN-resistant viruses are specifically selected from a pool of biologically diverse viruses during mucosal HIV-1 transmission.

45 The Dynamics of HIV-1 RNA Near the Plasma Membrane During Virus Assembly

Luca Sardo; Steven C. Hatch; Jianbo Chen; Olga A. Nikolaitchik; Ryan C. Burdick; De Chen; Christopher J. Westlake; Stephen Lockett; Vinay K. Pathak; Wei-Shau Hu
Frederick National Laboratory for Cancer Research, Frederick, MD, US

Background: HIV-1 must package its RNA genome to generate infectious particles. The interactions between viral RNA elements and the structural protein Gag are essential for efficient virus particle assembly. However, little is known about the dynamics and the events that lead to RNA packaging in living cells. We investigated 1) the window of opportunity for HIV-1 RNAs near the plasma membrane to interact with Gag and be packaged into viral particles, and 2) quantified the proportion of HIV-1 RNAs that, after reaching the plasma membrane, were packaged into assembling viral particles.

Methods: We labeled HIV-1 RNA with an RNA-binding protein fused to EOS, a photoconvertible protein whose fluorescence switches from green to red upon exposure to near-UV light. We selectively converted EOS near the plasma membrane of HeLa cells and followed the RNA signals over time by using total internal reflection fluorescence (TIRF) microscopy.

Results: In the absence of Gag, most of the HIV-1 RNAs stayed near the plasma membrane transiently, with ~50% of the RNAs departing within ~2 minutes; however, a portion of the RNAs (~20%) were detectable 30 minutes later. The presence of HIV-1 Gag increased the RNA retention time near the plasma membrane; most of the RNAs (~60%) were detected after 30 minutes. By tagging HIV-1 Gag with a blue fluorescent protein we observed that in the early phase of HIV-1 expression, when few or no Gag puncta are detected, ~10-40% of the HIV-1 RNAs that reached membrane were recruited into assembling particles.

Conclusions: These studies are the first measurements of HIV-1 RNA dynamics at the plasma membrane and the efficiency of RNA recruitment, which provide insights into the events leading to the generation of infectious HIV-1 virions.

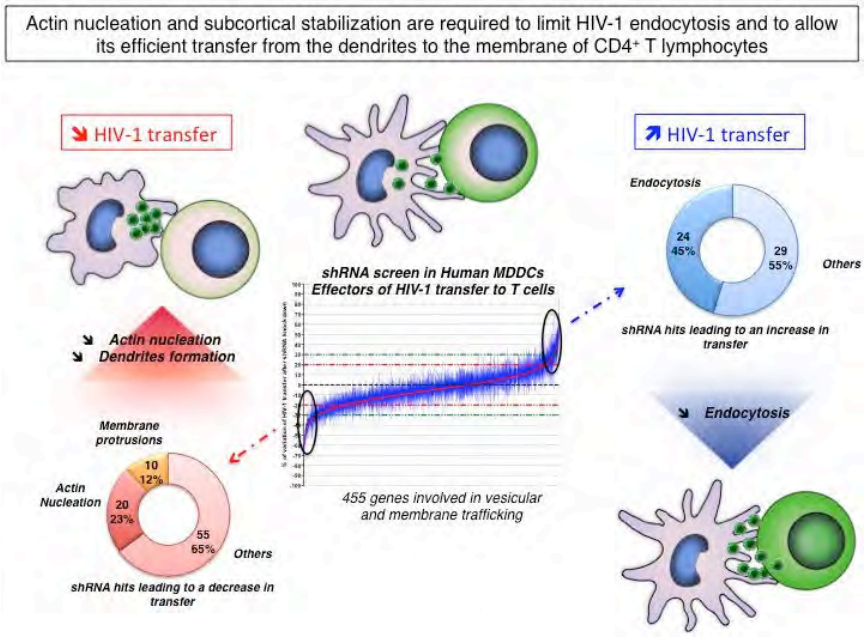
46LB Mechanisms of Dendritic Cell-Mediated Transfer of HIV-1 to CD4$^+$ T Lymphocytes

Mickael M. Menager[1]; Wendy Lin[1]; Jarrod S. Johnson[2]; Kristen Dancel-Manning[1]; Nicolas Manel[3]; Feng-Xia Liang[1]; Dan R. Littman[1]
[1]Skirball Institute of Biomolecular Medicine, New York, NY, US; [2]Seattle Biomedical Research Institute, Seattle, WA, US; [3]Institut Curie, Paris, France

Background: Dendritic cells (DCs) have essential roles in early detection of pathogens and in subsequent activation of both innate and adaptive immune responses, and are likely to be of critical importance in developing new strategies for protective HIV-1 vaccination. Whereas human DCs are resistant to productive viral replication, they have a unique ability to take up virus and transmit it efficiently to T lymphocytes. By doing that, the virus may evade, at least in part, the first line of defense of the immune system in mucosal tissues, exploiting DCs instead to facilitate rapid infection of a large pool of immune cells.

Methods: To gain insight into this cell biological process, we have used small hairpin RNA (shRNA) technology in primary monocyte-derived DCs (MDDCs) to suppress the expression of several hundred genes and analyze the impact on transfer of HIV-1 from DCs to T cells.

Results: By combining flow cytometry with confocal and electron microscopy experiments, we have identified and validated the function of TSPAN7 and DNM2 in viral transfer. These proteins appear to be involved in the control of actin nucleation and stabilization, which are important in limiting HIV-1 endocytosis and maintenance of virus on dendritic processes for efficient transfer to T lymphocytes. The requirement for actin nucleation and dendrite formation in HIV-1 transfer is strongly supported by 28 additional genes identified in the shRNA screen. Conversely, knock down of 24 genes linked to different types of endocytosis resulted in increased HIV-1 transfer.



Conclusions: This genetic approach is a first step towards a better understanding of the molecular and cell biological aspects of HIV-1 transmission between DCs and T lymphocytes, which is needed to evaluate the importance of this process in infected individuals. This approach should provide new tools and new targets for the design of therapies that limit viral replication and boost innate immune responses to control HIV dissemination.

New Discoveries in HIV Pathogenesis

47 Inflammation Persists Despite Early Initiation of ART in Acute HIV Infection

Netanya S. Utay[1]; Jintanat Ananworanich[2]; Suteera Pinyakorn[3]; Adam Rupert[5]; Duanghathai Sutthichom[3]; Suwanna Puttamaswin[3]; Bonnie M. Slike[2]; Nelson L. Michael[2]; Daniel C. Douek[4]; Irini Sereti[4]

[1]University of Texas Medical Branch at Galveston, Galveston, TX, US; [2]US Military HIV Research Program, Silver Spring, MD, US; [3]South East Asia Research Collaboration with Hawaii, Bangkok, Thailand; [4]National Institutes of Health (NIH), Frederick, MD, US; [5]Leidos Biomedical Research, Inc, Frederick, MD, US

Background: Biomarkers of microbial translocation, inflammation, coagulation and fibrosis predict morbidity and mortality in patients with chronic HIV infection. The effects of starting antiretroviral therapy (ART) in patients with acute HIV infection (AHI) on levels of these biomarkers in chronic treated infection are unknown and may illuminate the potential impact of early ART on clinical outcomes.

Methods: Subjects were diagnosed with acute HIV infection and initiated ART within 0-5 days per RV254 protocol. Plasma levels of D-dimer, C-reactive protein (CRP), hyaluronic acid (HA), soluble CD14 (sCD14) and intestinal fatty acid binding protein (I-FABP, a marker of enterocyte turnover) were measured by ELFA (D-Dimer), Mesoscale (CRP) and ELISA (HA, sCD14, I-FABP) from 109 HIV-uninfected (HIV-) and 78 AHI Thai participants at diagnosis (week 0), weeks 2, 12, 24, 36, 48 and 96. Median values were compared between HIV+ and HIV- groups by Mann-Whitney test and longitudinal within-group comparisons by Wilcoxon matched-pairs signed rank test.

Results: Median age was 28 years (range 24-33) for HIV+ subjects and 27 years (22-37) for HIV- subjects. 92.3% of HIV+ subjects and 77.1% of HIV- subjects were male. Median time since HIV acquisition was 16 days (12-22), CD4 T-cell count 384 (293-525) cells/mm^3 and HIV RNA 5.6 (5.1-6.3) $\log_{10}$ copies/mL. Twenty subjects were diagnosed in 4th generation (4thG) stage 1 (median 12 days post-acquisition), 15 in stage 2 (16 days) and 43 in stage 3 (18 days). All week 0 biomarker levels were significantly higher in HIV+ than HIV- subjects (see table). I-FABP increased by week 2 and remained elevated regardless of 4thG stage. Other biomarkers did not decrease in individuals diagnosed in 4thG1 until week 12. sCD14, CRP and HA decreased by week 2 in individuals diagnosed in 4thG2, and sCD14, CRP, HA and D-dimer decreased by week 2 in individuals diagnosed in 4thG3. HIV+ subjects had significantly higher levels of all biomarkers except D-dimer after 48 and after 96 weeks of ART compared to HIV- subjects.

Levels of biomarkers of microbial translocation, inflammation, coagulation and fibrosis

Conclusions: Enterocyte turnover increases after initiation of ART during acute infection and persists into chronic infection. Biomarkers of inflammation, microbial translocation and fibrosis decrease, but remain elevated compared to HIV- controls with the exception of D-dimer. Together, these data suggest that the inflammatory damage caused by HIV may not be completely prevented by starting ART during acute HIV infection

48 HIV Burden and Biomarker Associations With Colonic HIV RNA During Acute HIV Infection

James L. Fletcher[2]; **Trevor A. Crowell**[1]; Robin Dewar[3]; Irini Sereti[4]; Bonnie Slike[1]; Nitiya Chomchey[2]; Rungsun Rerknimitr[5]; Nelson L. Michael[1]; Nicolas Chomont[6]; Jintanat Ananworanich[1]
RV254/SEARCH010 Study Group

Background: The colonic mucosa is typically one of the first sites infiltrated during acute HIV infection (AHI), becoming an important reservoir for the virus and a barrier to cure. We investigated virologic and immunologic correlates of detectable colonic HIV RNA during AHI.

Methods: Subjects were prospectively enrolled and offered ART during AHI (Fiebig stages I-V) from May 2009 to March 2012 in Bangkok, Thailand. Sigmoidoscopy was performed to collect colon tissue. Subjects were categorized by detectable (≥50 copies/mg) or undetectable HIV RNA in colonic mucosal tissue cells using homogenized biopsy specimens and the Siemens Quantiplex HIV-1 3.0 assay. Biomarkers and HIV burden in multiple compartments were compared between groups using the Mann-Whitney U test.

Results: From 49,458 samples screened for HIV, 75 individuals were enrolled during AHI and 42 consented to optional colon biopsy and are included in this analysis. The median age was 29 and 93% were male. Colonic HIV RNA was detectable in 32 subjects (76%).

As compared to subjects without detectable colonic HIV RNA, those with detectable HIV RNA tended to be in a later Fiebig stage (19% Fiebig I in detectable group vs. 70% Fiebig I in undetectable group, p=0.04); had a longer reported duration since HIV exposure; had higher median levels of IP-10, TNF-RII and neopterin; and had higher expression of HLA-DR/CD38 and Ki-67 on CD8 cells in both blood and colon (Table 1). Median CD4 count in mucosal mononuclear cells was lower in volunteers with detectable colonic HIV RNA. Detectable colonic HIV RNA was also associated with higher HIV RNA levels in the peripheral blood and cerebrospinal fluid as well as higher levels of both total and integrated HIV DNA in both the peripheral blood and colon.

Among subjects with baseline detectable colonic HIV RNA, 23 of 26 tested (88%) were undetectable after 24 weeks of ART. The eight tested subjects who were undetectable at baseline remained undetectable.

Table 1. Characteristics of Subjects during Acute HIV Infection, Stratified by Colonic HIV RNA

Characteristic	Colonic HIV RNA ≥50 copies/mg [N=32]	Colonic HIV RNA <50 copies/mg [N=10]	p
	Median (IQR)	Median (IQR)	
Age (years)	29 (24 – 31)	28 (25-42)	**0.62**
Time since HIV exposure (days)	16 (14 – 22)	11 (8 – 16)	**0.02**
Peripheral Blood			
CD4 (cells/mm^3)	391 (339 – 564)	491 (311 – 565)	0.67
CD8 (cells/mm^3)	624 (409 – 1105)	421 (271 – 500)	**0.03**
CD4:CD8 ratio	0.56 (0.38 – 1.17)	1.14 (1.12 – 1.45)	**0.01**

Characteristics of Subjects during Acute HIV Infection, Stratified by Colonic HIV RNA

Conclusions: This study highlights the rapidity and breadth of viral infiltration during AHI. Detectable colonic HIV RNA is common and correlates with increase HIV burden in the peripheral blood, colon, and CSF. Subjects with detectable colonic HIV RNA during AHI demonstrate colonic CD4 depletion, peripheral inflammation, and CD8+ T-cell activation in both colon and periphery. Subjects with undetectable colonic HIV RNA tended to be at earlier stages of AHI.

49 Identification and Characterization of Individual HIV-Infected CD4 T Cells Ex Vivo

Joseph Casazza[1]; Irene Primmer[1]; David Ambrozak[1]; Constantinos Petrovas[1]; Sara Ferrando-Martinez[1]; Perla Del Río-Estrada[2]; Gustavo Reyes-Terán[2]; Ezequiel Ruiz-Mateos[3]; John Mascola[1]; Richard A. Koup[1]

[1]Vaccine Research Center, NIAID, NIH, Bethesda, MD, US; [2]Instituto Nacional de Enfermedades Respiratorias, Mexico City, Mexico; [3]HU Virgen del Rocio/IBIS, Sevilla, Spain

Background: Identification of live HIV-infected CD4 cells would allow the characterization of these cells by flow cytometry and single cell transcriptomic analysis.

Methods: bnAbs were screened for their ability to identify individual BaL-infected primary CD4 T cells as identified by P24 intracellular staining and transcription of Gag, and D1A3 (Tat-associated) and D1A4b (Rev-associated) spliced HIV RNA. CD4 mimic, V1V2 and the V3 glycan bnAbs were found that stained BaL-infected cells. bnAbs used for *ex vivo* studies were selected based on breadth of neutralization of B clade virus, and sensitivity and intensity of staining of HIV-infected CD4 T cells. Live $CD3^+CD45RO^+CD8^-CD14^-CD19^-TCR\delta\gamma^-$ CD4 dim and null cells prepared from lymph nodes were stained for expression of PD-1, CD57, CXCR4, CXCR5, CD27 and PGT121 and then bulk sorted into $PD\text{-}1^{++}$; $PD\text{-}1^-CD57^-$; and $PD\text{-}1^-CD57^+$ populations. Individual $PD1^+$ cells were index sorted into individual wells, RNA was extracted, purified, and Gag, and Rev- and Tat-associated RNA copy numbers determined by RT PCR. Measureable Tat- and Rev-associated HIV RNA were assumed to represent active transcription of HIV proviral DNA.

Results: The highest frequency of CD4 T cells transcribing proviral DNA was found in the $PD\text{-}1^+$, CD4 dim and null population. $PD\text{-}1^+$ cells were index sorted and Gag, Tat- and Rev-associated HIV RNAs measured. Ninety-one of 599 (15%) cells sorted from lymph nodes from six untreated, HIV-infected individuals, were actively transcribing HIV RNA. Eighty-five percent of the cells transcribing Tat- and Rev-associated RNA also contained measurable Gag RNA. Staining of HIV envelope by PGT121 was significantly associated with proviral DNA transcription ($P<0.0001$). Median percentage of $PGT121^+$ CD4 dim and null T cells actively transcribing virus was 41 (range, 12-64)% compared to 17(3-22)% in $PGT121^-$ cells. PGT121 staining was strongly associated with downregulation of CD4 ($P<0.0001$). A higher percentage of $CXCR5^+PD1^+$ cells actively transcribed proviral DNA than did $CXCR5^-PD\text{-}1^+$ cells ($P<0.0001$). A lesser proportion of $CD57^+$ CD4 T cells, a marker of germinal center cells, actively transcribed proviral DNA than did $CD57^-$ CD4 T cells ($P<0.05$).

Conclusions: Most CD4 T cells transcribing proviral DNA are Tfh cells. Viral transcription occurs both inside and outside of the germinal center in B cell follicles and is identifiable by bnAbs. bnAbs may be a means of targeting HIV-infected CD4 T cells in lymph nodes.

50 Efficacy of HIV-1 Monoclonal Antibody Immunotherapy in Acute SHIV-Infected Macaques

Diane L. Bolton[1]; Amarendra Pegu[2]; Keyun Wang[2]; Kathleen McGinnis[2]; Kathryn Foulds[2]; Srinivas Rao[2]; Merlin L. Robb[1]; Nelson L. Michael[1]; John Mascola[2]; Richard A. Koup[2]

[1]US Military HIV Research Program, Silver Spring, MD, US; [2]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD, US

Background: Highly potent broadly neutralizing HIV-1 antibodies (bNAb) can suppress viremia in both humanized mouse and macaque models of HIV-1 infection. However, the therapeutic potential of these antibodies during early acute infection (e.g. Fiebig I-III) is unknown. Recent clinical evidence indicates that antiretroviral therapy (ART) administered during this period suppresses both viremia and seeding of the viral reservoir. Here we test the ability of bNAb regimens to control acute simian-human immunodeficiency virus (SHIV) replication in rhesus macaques and compare efficacy to ART.

Methods: Rhesus macaques were infected with SHIV-SF162P3 followed by administration 10 days later of either 1) daily triple drug ART; 2) a single dose of Env CD4-binding site specific bNAb, VRC01; 3) a single dose of a combination of a more potent clonal relative of VRC01 (VRC07-523) and a V1/V2 glycan-dependent bNAb (PGT121); or 4) no treatment. Daily ART was initiated 11 days after bNAb. Plasma viremia and cell-associated viral load were measured to assess efficacy.

Results: A single infusion of VRC01 on day 10 reduced viremia by ~ 1 log10 over the next 10 days. The combination of VRC07 and PGT121 had a greater effect of between 2 and 3 log10 that was similar to treatment with ART. Following peak viremia, control was better sustained by the dual bNAb and ART regimens than the VRC01 regimen. Plasma bNAb concentrations exceeded IC80 values for at least 7 days in all animals. Proviral DNA in lymph node was also diminished after treatment with ART or dual bNAb, both effecting a ~1 log decline in SHIV copies per $CD4^+$ T cell. Decreased viral replication by these regimens was further evidenced by dampened cellular and humoral immune responses to viral antigens. Greater efficacy of VRC07-523 / PGT121 relative to VRC01 is consistent with more potent neutralization activity of these bNAbs against the SHIV-SF162P3 challenge virus.

Conclusions: Our findings demonstrate that potent neutralizing HIV-1-specific antibodies are at least as effective as ART at controlling acute virus replication. Moreover, bNAb immunotherapy may offer an advantage over ART in its ability to further reduce the proviral DNA burden. These data support future therapeutic clinical trials that investigate VRC01, and eventually other antibodies, as an alternative to or in conjunction with ART to treat Fiebig I-III HIV-1 infection.

51 HIV-1 Infections With Multiple Founders Are Associated With Higher Viral Loads

Holly Janes[1]; Sodsai Tovanabutra[2]; Joshua Herbeck[3]; Supachai Rerks-Ngarm[4]; Merlin L. Robb[2]; Nelson L. Michael[2]; Peter Gilbert[1]; Jerome H. Kim[2]; **Morgane Rolland**[2]
The Step/HVTN502 and RV144 study teams

[1]Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US; [2]US Military HIV Research Program, Silver Spring, MD, US; [3]University of Washington, Seattle, WA, US; [4]Thai Ministry of Public Health, Bangkok, Thailand

Background: A single HIV-1 genetic variant establishes infection in most subjects, including breakthrough infections in the Step/HVTN-502 and RV144 vaccine efficacy trials. We sought to evaluate whether characteristics of the founder viral populations could influence clinical outcomes in the infected participants, specifically whether subjects infected with multiple founder variants would exhibit higher viral loads or lower CD4+ T cell counts.

Methods: HIV-1 breakthrough sequences obtained by single genome amplification from plasma samples collected at diagnosis, and follow up clinical data were available from 63 Step/HVTN502 (MSM infected with HIV-1 subtype B) and 100 RV144 (heterosexuals infected with HIV-1 CRF01_AE) participants. Linear regression models were used to relate qualitative (homogeneous/heterogeneous infection) and quantitative (*env* diversity measures) viral predictors to clinical post-infection endpoints.

Results: Based on data collected up to 1 year post HIV-1 diagnosis, we found that subjects who had been infected with multiple founder viruses had significantly higher mean viral loads (0.37 $\log_{10}$ higher, $p = 0.007$ in Step and 0.29 $\log_{10}$ higher, $p = 0.024$ in RV144). Higher *env* diversity in the founder population was also associated with higher mean viral load (0.59 $\log_{10}$ higher per 10-fold increase in diversity, $p \leq 0.001$ in Step and 0.45 $\log_{10}$ higher per 10-fold increase in diversity, $p = 0.011$ in RV144). Moreover, in the RV144 cohort, subjects with more diverse HIV-1 founder populations had significantly lower CD4 T cell counts over time (heterogeneity predictor: $p = 0.020$, *env* diversity predictor: $p = 0.028$).

Conclusions: We showed that measures of increased HIV-1 diversity in early HIV-1 infection, both qualitative and quantitative, were associated with markers of poorer clinical outcomes. These results illustrate how consequential the first steps of HIV-1 infection are for clinical disease progression and suggest that limiting the number of viral variants establishing HIV-1 infection may be an important goal for HIV-1 preventive and post-infection disease attenuation strategies.

The views expressed are those of the authors and should not be construed to represent the positions of the US Army or the Department of Defense.

52 Post-Treatment Controllers Have Particular NK Cells With High Anti-HIV Capacity: VISCONTI Study

Daniel Scott-Algara[1]; Céline Didier[1]; Vincent Arnold[1]; Jean-Saville Cummings[1]; Faroudy Boufassa[2]; Olivier Lambotte[5]; Laurent Hocqueloux[4]; Asier Sáez-Cirión[1]; Christine Rouzioux[3]

[1]Institut Pasteur, Paris, France; [2]CESP U1018 Inserm, Le Kremlin-Bicêtre, France; [3]Laboratoire de Virologie, EA 3620–Université Paris Descartes Hôpital Necker, Paris, France; [4]Service des Maladies Infectieuses et Tropicales CHR d'Orléans–La Source, Orleans, France; [5]Hôpital Bicêtre, Le Kremilin-Bicêtre, France

Background: The association of T-cells with the control of HIV infection has been well documented. In addition, several studies pointed out the role on innate immune responses in the resistance or delay to HIV disease progression. The recent description (VISCONTI study) of a group of patients, so-called post-treatment controllers (PTCs), who remains with undetectable viral load after treatment interruption despite poor CD8+T cell responses, led us to study NK cells and their relationship to HIV control.

Methods: 14 patients enrolled in the French ANRS VISCONTI cohort were studied. PTCs' results were compared to those of Viremic patients, (VIR), natural HIV controllers (HIC), patients on ARV since acute infection (ARV) and normal blood donors (controls). All phenotypic studies were done on fresh whole blood. CD107a expression on NK cells and the ICS-based assay were done on PBMC after stimulation. NK cells were tested for their capacity to inhibit HIV infection (measured by intracellular or supernatant p24) in autologous CD4 T cells. Results obtained were compared using Wilcoxon rank sum test or by the Fisher exact test

Results: Visconti patients showed significantly higher expression of CD158a, CD158b (KIR2DL2/DL3), PTC showed significantly higher expression of CD158a, CD158b (KIR2DL2/DL3), CD158b/DX9 (KIR3DL1/3DS1) and NKG2A receptors ($p<0.002$, $p<0.001$, $p<0.0.01$, $p<0.001$, respectively) with lower expression of CD160 and NKp46 ($p<0.001$, $p<0.03$, respectively) receptors compared to others groups. Activation of NK cells from PTC and ARV, measured by CD69 marker, was similar to normal donors but lower than in HIC ($p<0.006$) or VIR patients ($p<0.001$). Functional studies when NK cells were stimulated by K562 cell line showed normal levels of degranulation (CD107a marker) but higher IFN-γ production for PTC than for other groups ($p<0.01$). NK cells from PTCs, but not from other individuals ($p<0.001$), were able to reduce p24 levels when co-cultured with in vitro-infected autologous CD4 T cells.

Conclusions: NK cells from PTC had a different NK cell repertoire and higher potential to produce IFN-γ compared to HIC, Viremic patients or normal donors, but similar to those treated since primary infection. More importantly, PTC NK cells showed high capacity to control in vitro HIV infection on autologous CD4 T cells. Our results suggest that preserving NK cell phenotype and function during acute infection is important to control HIV and identify NK cells as possible important agents in the durable remission of PTC.

53 Antiretroviral Therapy Preserves Polyfunctional HIV-1–Specific CD8 T Cells With Stem-Cell–Like Properties

Selena Vigano[1]; Jordi J. Negron[1]; Eric S. Rosenberg[2]; Bruce D. Walker[1]; Mathias Lichterfeld[2]; Xu G. Yu[1]

[1]The Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, US; [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US

Background: CD8 stem-cell like memory T cells (T_{SCM} cells) have been recently identified in humans, mice and non-human primates, and seem to represent the most immature memory CD8 T cell population with potent abilities to proliferate and repopulate the memory T cell pool. The presence and the function of CD8 T_{SCM} cells in HIV-1 positive individuals are unknown.

Methods: CD8 T_{SCM} cells were analyzed in 61 HIV-1-positive patients (31 with HAART-suppressed HIV-1 infection, 14 with untreated progressive HIV-1 infection, and 16 untreated HIV-1 controllers (viremia < 1000 RNA copies/ml). Phenotype and function of CD8 T_{SCM} cells were assessed by flow cytometry; virus-specific CD8 T cell populations (n=90 HIV-1-specific responses, n=24 CMV/EBV/Flu-specific responses) were identified by MHC class I multimer staining or intracellular cytokine staining. 12 HIV-1 negative study subjects were analyzed as controls.

Results: Levels of T_{SCM} in total CD8 T cells were significantly decreased in untreated HIV-1-infected patients ($p<0.007$), but not different between HAART-treated HIV-1 patients and HIIV-1-negative subjects. Among all HIV-1 patients, total and HIV-1-specific CD8 T_{SCM} cells were most frequent in HAART-treated patients ($p<0.0001$). CD8 T_{SCM} cell frequency was directly associated with years of treatment ($p<0.0001$, r=0.66) and inversely associated with immune activation ($p=0.007$, r=-0.3) and apoptosis ($p=0.03$, r=-0.27) levels. Moreover, HIV-1-specific CD8 T_{SCM} cells from HAART-treated patients showed the highest degree of polyfunctionality in comparison to the other groups of patients ($p<0.005$).

Conclusions: Polyfunctional HIV-1-specific CD8 T_{SCM} cells are able to persist long-term and show a relative accumulation during antiretroviral therapy when viral antigen is pharmacologically suppressed. Due to their apparent antigen-independent persistence in HAART-treated patients, these cells may play an important role in targeting the reservoir of HIV-1-infected cells after pharmacological reversion of viral latency.

54LB In Vitro Replication and Interferon-Alpha Resistance of Transmitted HIV-1 Variants

Zachary Ende[1]; Martin Deymier[1]; Angharad Fenton-May[2]; Daniel T. Claiborne[1]; William Kilembe[3]; Susan Allen[1]; Persephone Borrow[2]; Eric Hunter[1]

[1]Emory University, Atlanta, GA, US; [2]Oxford University, Oxfordshire, United Kingdom; [3]Zambia Emory HIV Research Project, Lusaka, Zambia

Background: Despite the diverse quasispecies of HIV-1 in the transmitting partner, a bottleneck occurs during transmission whereby, in general, a single genetic variant from that quasispecies establishes infection in the new host. The current working model explaining the transmission bottleneck suggests that transmitted/founder (TF) variants have a higher *in vivo* fitness and are preferentially resistant to the innate antiviral effects of interferon alpha (IFNα), enabling escape from the early innate immune response. However, variants derived from HIV-1 transmission pairs with the full complement of HIV proteins have yet to be tested for IFNα resistance or *in vitro* replication. In this study, we assess replication and IFNα resistance of infectious molecular clones derived from both partners from six transmission pairs to compare the TF to non-transmitted (NT) variants that were present near the time of transmission.

Methods: Using a novel cloning strategy, we generated 44 HIV-1 subtype-C full-length infectious molecular clones (6 TF & 38 non-transmitted (NT) variants) from plasma of 6 linked transmission pairs near the time of transmission from the Zambia-Emory HIV Research Project (ZEHRP). The NT variants were selected to represent the sequence diversity of the transmitting partner. We measured virus growth in stimulated PBMC and compared the levels of replication in the presence and absence of IFNα to determine IFNα resistance of the TF and NT variants.

Results: We found no evidence of selection for IFNα resistance during heterosexual transmission ($p=0.7813$), when comparing the TF to matched NT variants. We also did not observe selection for TF varaints with higher *in vitro* replicative capacity than the median of the matched NT variants ($p=0.7118$). Notably, the *in vitro* replicative capacity of each variant correlated with the ability to replicate in the face of IFNα ($p<0.0001$) and replicative capacity correlated negatively with IFNα resistance ($p<0.0001$).

Conclusions: Our results emphasize the importance of comparing TF variants to NT controls near the time of transmission and suggest that IFNα resistance and *in vitro* replicative capacity are not necessarily selected for during transmission of subtype C HIV-1 variants. Further characterization of TF variants is necessary to fully understand the viral properties selected for during the HIV-1 transmission bottleneck and to optimize protection through vaccines or other prevention modalities.

55LB HVTN505 Breakthrough Sequences Show HIV Vaccine-Associated Differences in Env-gp120

Morgane Rolland[1]; Allan deCamp[2]; Breana M. Hall[3]; Sodsai Tovanabutra[1]; Mario Roederer[4]; Scott M. Hammer[5]; Magdalena E. Sobieszczyk[5]; Peter B. Gilbert[2]; Jerome H. Kim[6]; James Mullins[3]
The HVTN505 Sieve Analysis Group

[1]US Military HIV Research Program; Henry M. Jackson Foundation for the Advancement of Military Medicine Inc, Silver Spring, MD, US; [2]Fred Hutchinson Cancer Research Center, Seattle, WA, US; [3]University of Washington, Seattle, WA, US; [4]Vaccine Research Center, Bethesda, MD, US; [5]Columbia University, New York, NY, US; [6]US Military HIV Research Program, Silver Spring, MD, US

Background: The HVTN505 HIV vaccine study enrolled 2,504 US participants in a phase IIb test-of-concept efficacy trial of a DNA/rAd5 vaccine expressing Gag/Pol/Nef from subtype B and Env proteins from subtypes A/B/C. Although the vaccine showed no efficacy with respect to HIV acquisition or post-infection viral load (Hammer, NEJM, 2013), we analyzed breakthrough HIV isolates to evaluate potential sieve effects.

Methods: Sequencing was performed following PCR amplification of near full-length single HIV genomes derived from plasma specimens at HIV diagnosis. Phylogenetic and statistical analysis methods assessed individual genes, k-mers, and amino acid (AA) sites to compare breakthrough sequences from vaccine and placebo recipients, with multiplicity adjustment procedures (20% false discovery rate).

Results: We characterized 480 HIV genomes from 27 vaccine and 20 placebo recipients. All infections were with subtype B. Infections were established by multiple founder variants in 5 of 26 vaccine recipients (19%) and in 8 of 20 placebo recipients (40%) (Fisher's exact test, p= 0.19). Two vaccine recipients were infected by two phylogenetically-unrelated viruses (*env* diversity= 8.9% vs 0.3% for other subjects). Intra-host diversity was significantly lower in vaccine than placebo recipients for Gag, Pol, Env-gp120 and Vif proteins ($p \leq 0.04$, $q \leq 0.09$).

The distance between founder and vaccine sequences was measured for each participant and compared across treatment groups. While differences in other proteins were not significant, Env-gp120 sequences from vaccine recipients were significantly more distant from the subtype B vaccine insert than sequences from placebo recipients (median = 0.30 vs 0.29; Mann-Whitney test, p= 0.01, q= 0.12).

Vaccine/placebo AA differences in Env-gp120 were identified at six 9-mers starting at HXB2 positions 28, 86, 193, 365, 427, and 467, and at site 133 ($p < 0.005$, $q < 0.2$). Mapping of the 9-mer starting at AA193 on a trimer structure showed these residues in contact with the tip of the V3 loop of another monomer, thus possibly affecting the binding of V3-specific antibodies (Fig.1) – an interesting finding as the HVTN505 vaccine regimen elicited strong anti-V3 responses.

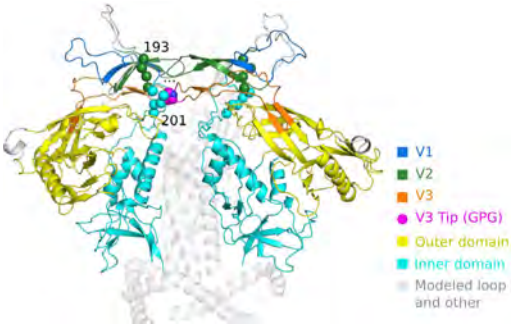

Figure 1. Env-gp120 residues corresponding to the 9-mer starting at HXB2 position 193 that distinguished the vaccine and placebo groups are figured with circles on the BG505. SOSIP structure (PDB ID: 4NCO). The start and end residues of the 9-mer (AA193 and 201) are numbered on the monomer on the left, the residues are colored in green and turquoise with a mirror image on another monomer. At the tip of the V3 loop, GPG is in magenta, with the 5 atoms in the proline's ring shown as spheres (the N atom being a blue sphere, carbon atoms in magenta).

Conclusions: Our results suggest an HVTN505 vaccine-driven sieve effect against Env-gp120. Analysis of breakthrough HIV isolates in vaccine efficacy trials is important to assess whether a vaccine elicited a selective pressure *in vivo* and to identify which responses are associated with efficacy and which are not.

Themed Discussion Abstracts

258 PCR-Free Full Genome Characterization of Diverse HIV-1 Strains by Nextgen Sequencing

Viswanath Ragupathy[1]; Feng Gao[2]; Ana Sanchez[2]; Marco Schito[3]; Thomas Denny[2]; Michael Busch[4]; Jiangqin Zhao[1]; Christelle Mbondji[1]; SaiVikram Vemula[1]; Indira Hewlett[1]

[1]US Food and Drug Administration, Silver Spring, MD, US; [2]Duke Human Vaccine Institute and Departments of Medicine, Duke University Medical Center, Durham, NC, US; [3]Henry Jackson Foundation, DAIDS, NIAID, Bethesda, MD, US; [4]Blood Systems Research Institute/University of California San Francisco, San Francisco, CA, US

Background: HIV-1 genotyping is an important tool for clinical and epidemiological studies. High level of genetic variation, recombination and mutations pose difficulty in successful PCR amplification of HIV-1 genomes. In addition, new emerging subtypes may not be detected with standard PCR primers. Here, we report a novel PCR-free multiplex method for characterization of full length HIV-1 genomes (~9.7kb) using the Nextgen RNA Seq approach.

Methods: A total of 27 diverse HIV-1 strains representing subtypes A-G, CRFs, URFs and Group O were obtained from the Global HIV-1 diversity panel that was assembled at the Duke EQAPOL. Viral RNA was extracted, reverse transcribed as described in the Illumina Truseq RNA Kit and sequenced using the MiSeq platform. Sequence reads were quality filtered and reference mapped using CLC genomic work bench software v6.0.4. Consensus sequences were generated for each virus and used for phylogenetic tree analysis using the neighbor-joining method based on the Kimura two-parameter substitution model and recombination patterns were determined using Simplot. Drug resistance was inferred from the Stanford HIV drug resistance program, and co-receptor usage was determined using the Geno2Pheno (g2p) 5-10% FPR.

Results: The multiplex RNA sequencing approach yielded >10000x coverage for each of the viral genomes. Pools of viral isolates were de-multiplexed and discriminated using bio-informatics. After filtering reads specific for HIV-1, each position in the viral genome had >1000x coverage. This approach enabled reconstruction of whole genome HIV-1 haplotypes accurately including flanking LTRs. Analysis of full HIV-1 genome sequences using Simplot correctly identified 15 pure subtypes, one Group O virus, and recombination patterns of 8 CRFs and 3 URFs. All these HIV subtypes identified were comparable to Sanger sequencing. In addition, this approach revealed NNRTI, integrase and protease drug-specific minor variants and drug resistance mutations with >1000x coverage. The g2p analysis predicted 89% of isolates as being R5 tropic, and the remaining were identified as X4 tropic.

Conclusions: We have developed a reliable, PCR-free and multiplexing approach to characterize whole HIV-1 genome sequences. This novel PCR-free method can be used for characterization of new, emerging unknown subtypes or recombinants and to reduce PCR-derived sequence errors. The multiplexing approach makes this NGS method more cost-effective and less labor-intensive than conventional methods.

257 Pan-HIV Next-Gen Sequencing Strategy for Viral Surveillance

Michael G. Berg[1]; Julie Yamaguchi[1]; Elodie Alessandri-Gradt[2]; Jean-Christophe Plantier[2]; Catherine Brennan[1]
[1]Abbott Laboratories, Abbott Park, IL, US; [2]Virology Unit, National Reference for HIV, Rouen, France

Background: The complexity of HIV strains has increased significantly due to natural evolution and inter-subtype recombination; recombination is now a worldwide problem. Thus, complete genome sequencing is essential to monitor HIV diversity accurately within populations. Next-generation sequencing (NGS) has the potential to revolutionize strategies for HIV surveillance. We have developed a universal method that permits full genome sequencing of all HIV-1 groups (M, N, O, and P) and HIV-2.

Methods: Reverse transcription primers, designed in conserved regions of HIV and spaced at 1.5-2kb intervals, fuse viral sequences to a common adaptor (SMART) sequence. This same adaptor is added to the 3' end of the cDNA to permit PCR amplification of libraries, which are then tagmented with Nextera XT for multiplexing and sequencing on an Illumina MiSeq. HIV sequences are extracted and assembled in CLC-Bio software (Qiagen) and classified by phylogenetic analysis using PHYLIP and SIMPLOT.

Results: Broad application of the approach was demonstrated using a panel of virus isolates (n=47) derived from cell culture that included 27 group M (different subtypes and CRFs), 16 O, 2 N, 1 P, and 1 HIV-2. In a single run multiplexing 23 libraries, 100% genome coverage was obtained for each at a median depth of 2100X, with HIV reads comprising 9.4% (median) of the total. A Cameroonian HIV-1 non-subtype B specimen was used to optimize the protocol for plasma. An NGS run of 8 high titer (>5.0_{log} copies/ml) clinical specimens, infected with diverse group M subtypes, yielded 96-100% coverage for each at a median 433X depth. Method sensitivity, demonstrated by serial dilution, showed that >50% of a genome could be obtained from a clinical specimen with a viral load ≥3.8_{log} copies/ml (100 RNA copies input). Due to inherent variability in sample background, coverage varied widely among specimens with viral loads <4.5_{log}. Nevertheless, sufficient sequence was obtained for strain classification. From the 55 novel full-length HIV sequences determined in this study, 5 are unique recombinants.

Conclusions: The HIV-SMART approach harnesses the specificity of HIV-directed priming without *a priori* knowledge of the viral strain present. This technology provides an unparalleled opportunity to identify diverse HIV strains in patient specimens and to determine phylogenetic classification based on the entire viral genome, illustrating the utility of NGS for viral surveillance.

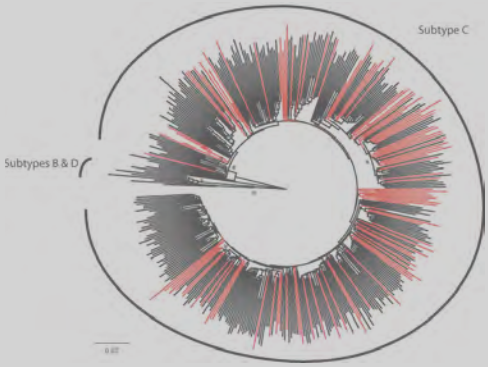
256 Near Full Length HIV-1 Sequencing to Understand HIV Phylodynamics in Africa in Real Time

Siva Danaviah; Justen Manasa; Eduan Wilkinson; Sureshnee Pillay; Zandile Sibisi; Sthembiso Msweli; Deenan Pillay; **Tulio de Oliveira**
University of KwaZulu-Natal, Durban, South Africa

Background: HIV transmission continues in Africa at alarming rates despite biological and behavioural interventions. Understanding the drivers of HIV transmission and evolution and translating the results into effective interventions is a key component of halting the epidemic. Recent technological advancement in complete genome sequencing has expanded the breadth and speed of genomic analyses currently possible. We have constructed a high-throughput genomics and bioinformatics pipeline that has successfully generated high quality complete HIV genomes in a hyper-endemic region of South Africa (SA), through the PANGEA_HIV Consortium

Methods: HIV RNA was extracted from plasma from patients failing antiretroviral therapy, within the Africa Centre (AC) research area and 4 overlapping regions spanning the 9.7kb complete HIV genome were amplified in a one-step RT-PCR strategy optimised for subtype C virus. Pooled amplicons were sequenced on an Illumina MiSeq. Fragments were quality controlled with SMALT software and assembled using two independent strategies (de novo and mapping to reference) in Geneious. Resulting consensus sequences were aligned against published HIV complete genomes from South Africa (n=300). Bayesian and maximum likelihood trees with branch support were reconstructed in PhyML and MrBayes.

Results: Amplification success rate of complete genomes, on samples with viral loads >10,000 c/ml was 85%. Near complete HIV genomes were generated for 117/117 samples sequenced thus far, with all nine open reading frames, the U5 / partial R region of the 5' LTR and partial U3 of the 3' LTR represented. Coverage of the HIV genome averaged 99.9% with a mean depth of coverage of 15 539 times (range = 21-48 767 times). Phylogenetic reconstruction confirmed that the AC strains were all HIV-1 subtype C where 36/117 sequences clustered with other complete genomes from SA. The discrete AC clusters (n=22) suggested multiple independent introductions of subtype C into the surveillance area and onward transmission within the population.



Maximum likelihood tree of 117 Africa Centre near full length HIV-1 complete genomes and 300 HIV-1 C genomes from South Africa. The tree is rooted on reference strains of subtypes B & D, branch support (bootstrap > 90) are marked with an *.

Conclusions: This is the first report, to the best of our knowledge, of a high-throughput complete HIV genome sequencing and analysis pipeline in Africa. The genetic diversity of HIV variants in this population is high and is mediated primarily by multiple introductions of HIV. Interventions therefore must be cognizant of the dynamics that drive these independent introductions in order to impact on going HIV transmission.

254 Present Applications of a High-Throughput, Single Measure HIV Genomic Incidence Assay

Sung Yong Park[1]; Tanzy Love[2]; Nolan Goeken[1]; Robert Bolan[3]; Alan S Perelson[4]; Michael Dube[1]; **Ha Youn Lee**[1]
[1]Keck School of Medicine at University of Southern California, Los Angeles, CA, US; [2]University of Rochester School of Medicine and Dentistry, Rochester, CA, US; [3]Los Angeles Gay and Lesbian Center, Los Angeles, CA, US; [4]Los Alamos National Laboratory, Los Alamos, CA, US

Background: Annual HIV incidence is the primary assessor for monitoring the epidemic's rise and decline. In pursuit of an accurate assay, we have proposed a genomic incidence assay utilizing fingerprints harbored in the HIV sequence population, which showed over 95% accuracy among 182 incident and 43 chronic samples. Still, two major hurdles must

be overcome before routine use in cross-sectional settings: 1) streamlining the cost and workflow, 2) ensuring proper classification between multiple-founder recent infections and chronic infections.

Methods: For enhancing the cost efficiency of the sequence-based assay, we developed a high-throughput next-generation sequencing platform; a signal-masking bioinformatics pipeline was devised to analyze 18,434 envelope gene segments (HXB2 7212-7601) obtained from 12 incident and 24 chronic patients. To give the assay power to appropriately discriminate multiple-founder recent infections from chronic infections, we formulated a mathematical model which posits the intersequence nucleotide base difference distribution of each subject's sequence sample as a function of infection duration and the number of founder sequences. This model was tested by analyzing HIV subtype B and C samples from 40 incident subjects with multiple founder viruses.

Results: First, the cost-effective pyrosequencing platform correctly classified all 12 incident subjects (100% sensitivity) and 23 out of 24 chronic subjects (96% specificity). Our signal-masking bioinformatics pipeline yielded a process error rate of 5.8×10^{-4} per base. Sampling simulations showed that the biomarkers were tolerant of the two factors most likely to affect the accuracy: sequencing errors and template resampling. Second, a quantitative guideline for segregating viral lineages was provided by our mathematical model, enabling us to assess when each subject was infected. The infection periods obtained from our model estimates and from Fiebig laboratory staging showed a statistically significant linear relationship ($p<0.0005$), correctly identifying all 40 individuals with incident infections.

Conclusions: The high-throughput platform permits the assay to be cost-effective, and when it is combined with our mathematical model, we can obtain recency signatures from the complex gene pool that arises from multiple founder viruses. Our sequence-based approach marks significant progress towards accurate determination of HIV incidence from genomic readouts measured from cross-sectional samples from a single blood draw.

255 A Comprehensive Analysis of Primer IDs to Study Heterogenous HIV-1 Populations

David Seifert[1]; Armin Töpfer[1]; Francesca Di Giallonardo[2]; Stefan Schmutz[2]; Huldrych F. Günthard[2]; Volker Roth[3]; Niko Beerenwinkel[1]; Karin J. Metzner[2]

[1]ETH Zurich, Basel, Switzerland; [2]University Hospital Zurich, Zurich, Switzerland; [3]University of Basel, Basel, Switzerland

Background: Haplotyping of HIV-1 populations is an essential step to better understand the evolutionary dynamics of the virus. With the advent of next-generation sequencing (NGS), haplotyping of viral populations has become feasible. Since HIV-1 is highly heterogeneous, several statistical methods have been devised to deal with error-prone NGS data, however, they often do not capture the population correctly. In order to correct for errors, the use of PrimerIDs (primer identifiers) has been proposed. Here, we used PrimerIDs to systematically estimate different enzymatic error rates and to comprehensively study the feasibility of PrimerIDs.

Methods: Plasmids containing full-length genomes of 5 HIV-1 clones were separately amplified in bacteria and then transfected into 293T cells. Generated infectious HIV-1 particles were pooled, DNase treated, and a fragment of the *pol* gene was reverse transcribed with SuperScript III reverse transcriptase (RT) and primers containing random 10-mers. Reverse transcription was performed in six independent replicates. Subsequently, nested PCR was performed using Platinum Taq DNA Polymerase followed by adapter ligation and sequencing with Illumina MiSeq.

Results: From an average number of 1.1 million reads, we called consensus sequences for PrimerIDs, each supported by at least 10 sequencing reads, to yield on average 11,000 consensus sequences per replicate. From these consensus sequences, we could call all mutant bases from the five reference viruses. We estimated a RT error rate of 6.23e-4 (95% CI: [6.13e-4, 6.32e-4]). We inferred the recombination rate of the RT to be 3.44e-5 (95% CI: [2.26e-5, 4.92e-5]). The PCR substitution rate of 1.18e-4 (95% CI: [1.14e-4, 1.22e-4]) was determined from those mutants having arisen in the first cycle of the PCR. We calculated the total number of transcribed RNAs to be on the order of 60,000 from the observed collision rate of 2%. We observed no sequence-specific bias in PrimerID frequencies, the same RT efficiencies as compared to commonly used short, specific RT primers, and no effects of primerIDs on the estimated distribution of the five viruses in the mix.

Conclusions: PrimerIDs allow for determining error rates in RT-PCR-NGS protocols and are applicable to study HIV-1 heterogeneity when attention is paid to collision rates. Given these advantages, the protocol is still labor- and cost-intensive and does not significantly improve on the variance of frequency estimates.

593 Analysis of Resistance Haplotypes Using Primer IDs and Next Gen Sequencing of HIV RNA

Valerie F. Boltz[1]; Jason Rausch[1]; Wei Shao[2]; Charles Coomer[1]; John W. Mellors[3]; Mary Kearney[1]; John M. Coffin[4]

[1]National Institutes of Health (NIH), Frederick, MD, US; [2]Leidos, Frederick, MD, US; [3]University of Pittsburgh, Pittsburgh, PA, US; [4]Tufts University, Boston, MA, US

Background: Targeted sequencing technologies using primer IDs can result in more accurate representations of HIV-1 populations but PCR bias and recombination have hampered progress. Here we describe a new method for library construction that produces a larger number of tagged consensus sequences, increases sensitivity of haplotype determination, and reveals the sources of recombination.

Methods: Each molecule of cDNA from mixtures of varying percentages of wild-type and mutant HIV-1 *pol* transcripts containing 14 drug resistance mutations was tagged uniquely using a gene-specific primer with primer IDs. cDNAs were then PCR amplified using two methods: (1) 90mer primers containing required MiSeq sequences; (2) 22mer primers containing uracil followed by digestion, cleavage and ligation to linkers containing MiSeq sequences. DNA was sequenced using paired-end MiSeq Illumina technology and consensus sequences were derived from a super-majority (≥80% consensus) for each unique ID. Consensus sequences were analyzed for PCR bias, errors, recombination, and sensitivity for detecting haplotypes.

Results: Of the total cDNA molecules used as template, amplified cDNA with unique tags ranged from 3-19% for method 1 and from 15-52% for method 2. The average error rates for method 1 and 2 were $9.3\text{x}10^{-5}$ and $1.4\text{x}10^{-4}$, respectively, both comparable to RT error rates. The PCR recombination rate for method 1 was 0.16% but only 0.01% for method 2. Method 1 was able to detect drug resistance mutations down to 0.01% and method 2 down to 0.001%. The sensitivity of haplotype detection was better for method 2: for samples containing 10% or 1% mutant, method 1 never detected linkage of all 14 mutations, whereas method 2 detected all 14 33-35% of the time. Method 2 always detected linkage of the 8 mutations nearest the 3′ end of the amplicon suggesting that PCR recombination is due to incomplete cDNA synthesis.

Conclusions: A linker ligation method of amplifying tagged cDNA reduced both PCR bias and recombination rate compared to standard methods, and was superior at detecting haplotypes within 200bp of the 3′ end of the template. However, it correctly detected linkage across the entire 570bp amplicon in only 1/3 of sequences, suggesting that cDNA synthesis is typically incomplete leading to PCR recombination and thus limiting sensitivity for detection of linked mutations. Improved methods are needed for cDNA synthesis to increase the reliability of haplotype determination for HIV-1 populations.

300 Effect of CMV and HIV Replication on T-Cell Exhaustion and Senescence During ART

Jennifer M. Dan[1]; Marta Massanella[1]; David M. Smith[1]; Eric S. Daar[2]; Michael P. Dube[3]; Richard Haubrich[1]; Sheldon Morris[1]; Sara Gianella Weibel[1]

[1]University of California San Diego, La Jolla, CA, US; [2]Harbor–University of California Los Angeles Medical Center, Torrance, CA, US; [3]University of Southern California Keck School of Medicine, Los Angeles, CA, US

Background: HIV-infected men who have sex with men (MSM) are nearly universally infected with CMV, and both viruses are associated with T-cell dysfunction and inflammation-related morbidities. The effect of asymptomatic CMV replication and persistent HIV transcription during suppressive ART on markers of T cell exhaustion and senescence is poorly defined.

Methods: Paired seminal and blood samples from 45 asymptomatic chronically HIV-infected CMV-seropositive MSM on long term ART and with HIV RNA levels in blood plasma <50 copies/ml were studied. Levels of CMV DNA in semen and blood were measured by RT-PCR, and cell-associated HIV DNA and RNA transcripts (unspliced) were measured in PBMC by droplet digital PCR. Markers of T cell exhaustion (PD-1) and senescence (CD57) were measured in PBMC by flow cytometry for CD4 and CD8 T cells and subsets (naïve [$CD45RA^+CD27^+CD28^+$], central memory [$CD45RA^-CD27^+CD28^+$], effectors [$CD4^+CD45RA^{-/+}CD27^-CD28^+$ or $CD8^+CD45RA^{-/+}CD27^+CD28^-$] and terminally differentiated [$CD45RA^{+/-}CD27^-CD28^-$]). Associations between immunological markers and asymptomatic CMV and HIV replication, HIV DNA, CMV IgG, age, current and nadir CD4 and time on ART were determined using univariate and multivariate analysis.

Results: CMV DNA was detected in 42% of seminal samples and 20% of PBMC. Detectable CMV DNA in semen but not blood was associated with increased PD-1 expression on circulating CD4 T cells compared to no CMV (P=0.01), particularly in the effector and terminally differentiated subsets (P<0.05). Similarly, higher levels of cellular HIV RNA (but not HIV DNA) were positively associated with greater PD-1 expression on total CD4 and central memory blood subset (P<0.01). There was no association between CMV DNA (blood and semen) or cellular HIV RNA with CD8 exhaustion or senescence or with markers of CD4 senescence. In multivariate analysis, detection of seminal CMV and higher cellular HIV RNA remained associated with increased PD-1 expression on total CD4 T cells (P<0.05). No other variable contributed significantly to the model.

Conclusions: Our data suggest that detection of CMV in the genital tract may contribute to the activation of the PD-1 axis on circulating T cells during suppressive ART. Because increased PD-1 on T cells has been implicated in the maintenance of the HIV reservoir, HIV disease progression and the inability of the immune system to adequately control HIV infection, future studies should examine whether CMV-dependent mechanisms play a role in T cell exhaustion.

301 HIV Myeloid Derived Suppressor Cells Control Cytomegalovirus Inflammation by IL-27

Ankita Garg; Stephen Spector
University of California San Diego, La Jolla, CA, US

Background: CMV is associated with persistent inflammation in HIV-infected persons. Here, we studied the effect of HIV expanded myeloid derived suppressor cells (MDSCs) in controlling CMV specific inflammation.

Methods: PBMCs from HIV–/CMV-seropositive (CMV+) donors were cultured in presence of heat inactivated HIV. After 5 days, $CD11b^+CD33^+CD14^+HLA\ DR^{hi}$ (DR^{hi} monocytes) and $CD11b^+CD33^+CD14^+HLA\ DR^{-/lo}$ (MDSCs) cell subsets were sorted by flow cytometry. B7H4 (a negative regulator of T cell function) was silenced using siRNA and cultured with/without autologous PBMCs in presence/absence of CMV pp65 peptides (pp65; 1μg/ml). In some experiments, PBMCs were cultured with HIV/pp65 in presence/absence of neutralizing anti-IL-27 antibody. Enumeration of B7H4 on MDSCs, regulatory T-cells, intracellular IFNγ, activated forms phospho(p)-Zap70 and p-Akt were determined by flow cytometry; IFNγ and IL-27 were quantified by ELISA. Data were analyzed using two-tailed, paired Student's *t* test.

Results: MDSCs cultured with autologous PBMCs exposed to pp65 caused a decrease in IFNγ production vs. controls or DR^{hi} monocytes (p=0.002). IFNγ release was restored when MDSCs were transfected with B7H4 siRNA and cultured with PBMCs in presence of pp65 (p=0.02). MDSCs cultured with PBMCs did not alter pp65 induced activation of proximal T-cell signaling molecule Zap70 but decreased activation of Akt; this was restored when B7H4 was knocked down in MDSCs cultured with PBMCs. Culture of MDSCs with pp65 produced more IL-27 vs. control MDSCs and DR^{hi} monocytes (p=0.05). Culture of CMV+ PBMCs with pp65 increased the frequency of $CD4^+IFN\gamma^+$ cells and release of IFNγ in supernatants vs. controls (p=0.04). IFNγ was further increased when PBMCs were cultured in presence of anti-IL-27 and stimulated with pp65; CMV– PBMCs did not produce IFNγ when treated with pp65. Furthermore, culture of CMV+ PBMCs with pp65 led to expansion of $FoxP3^+$ Tregs vs. controls (p=0.02) and CMV– (p=0.003); addition of anti-IL-27 had no effect on Treg expansion. Finally, HIV expanded MDSCs had increased expression of B7H4 when compared to DR^{hi} monocytes (p=0.03) which was inhibited in the presence of anti-IL-27 neutralizing antibody (p=0.05).

Conclusions: These findings suggest that IL-27 down regulates IFNγ during CMV infection. IL-27 induces B7H4 expression on HIV MDSCs which controls CMV induced T-cell IFNγ production by inhibiting p-Akt. IL-27 and B7H4 provide new therapeutic targets to control inflammation during HIV infection.

302 Persistent Elevation of Inflammation Markers in HIV+ Persons With CMV Disease

Melissa Schechter[1]; Bruno Andrade[2]; Eleanor M. Wilson[1]; Virginia Sheikh[2]; Sonya Krishnan[2]; Margaret Caplan[1]; Gregg Roby[2]; Adam Rupert[3]; Peter Burbelo[4]; Irini Sereti[2]
[1]NIAID, Leidos Biomedical Inc., Fredrick, MD, US; [2]National Institute of Allergy and Infectious Diseases, Bethesda, MD, US; [3]NIAID, Leidos Biomedical Inc., Fredrick, MD, US; [4]National Institute of Dental and Craniofacial Research, Bethesda, MD, US

Background: HIV+ individuals have a high prevalence of cytomegalovirus (CMV) co-infection and a minority of them develop CMV-associated end organ disease (EOD). CMV co-infection has also been associated with increased risk for cardiovascular events. The potential contribution of CMV infection or disease in chronic immune activation and non-infectious complications in HIV remains unclear.

Methods: In a case control study, HIV+ persons (CD4 <100 cells/μL pre-ART) with CMV EOD (N=25) or detectable CMV viremia (N=7) pre-ART were matched 1:1 by CD4 T-cell counts and age with HIV+ persons with undetectable CMV viremia by PCR. Participants were evaluated pre-ART (week 0) and at week (W) 12 and 48 after ART initiation. Cryopreserved plasma was used to measure markers of inflammation (CRP, IFN-γ, IL-12 p70, IL-10, IL-1β, IL-8, IL-6, TNF-α), monocyte activation and vascular injury (sICAM-3, E-Selectin, sCD14, sTF, MP-TF, CX3CL1, P-Selectin, Thrombomodulin, SAA, MCP-1, Eotaxin-3) and coagulation (D-dimer, Factor X Chromogenic, TF Chromogenic) by ELISA-based assays. Data were analyzed using Mann-Whitney and Spearman rank (correlation) tests.

Results: EOD cases were 66% male, with median age of 41 years, CD4 of 11 cells/μL, plasma HIV RNA of 5.12 $\log_{10}$ c/mL and CMV PCR 2.93 $\log_{10}$ c/mL units at W0. EOD cases had higher plasma levels of HIV RNA (p=0.01), CRP (p=0.03), IFN-γ (p=0.02), IL-10 (p=0.01), IL-8 (p=0.01), IL-6 (p=0.03), and SAA (p=0.001) compared to controls at W0. At W12, SAA (p=0.02), IFN-γ (p=0.0002), IL-10 (p=0.0003), IL-8 (p=0.01) and TNF-α (p=0.003) remained higher in EOD cases than in controls. At W48, IFN-γ (p=0.0.01), TNF-α (p=0.02) and IL-12 p70 (p=0.04) were persistently higher in EOD cases than in controls. Baseline, CMV IgG levels inversely correlated with sCD14 (r=-0.3, p=0.04), Fractalkine (r=-0.3, p=0.02) and HIV viral load (r=-0.33, p=0.01) but not with presence of EOD.

Conclusions: CMV end organ disease and viremia in HIV+ persons is associated with increased plasma levels of inflammatory and vascular injury biomarkers pre-ART with some persisting after ART. Our data suggest a protracted inflammatory response to CMV that may contribute to HIV pathogenesis and non-infectious complications.

Funded by NCI Contract No. HHSN261200800001E. This research was supported [in part] by the National Institute of Allergy and Infectious Diseases.

303 sCD163 Increase in HIV/CMV-Coinfected Subjects Included in ICONA Cohort

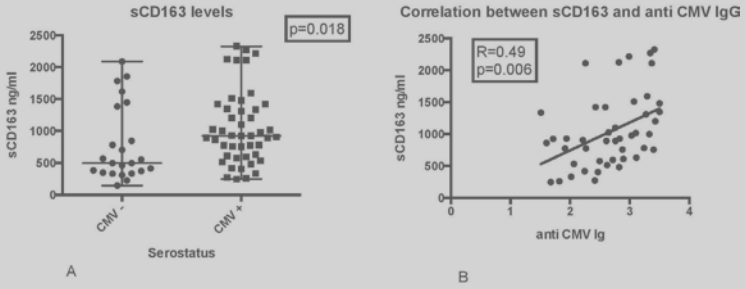
Serena Vita[3]; Miriam Lichtner[1]; Giulia Marchetti[2]; Claudia Mascia[3]; Esther Merlini[2]; Paola Cicconi[2]; Vincenzo Vullo[3]; Pier Luigi Viale[5]; Alberto Costantini[4]; Antonella d'Arminio Monforte[2]
For the Icona Foundation Study

[1]University of Rome La Sapienza, Polo Pontino, Latina, Italy; [2]San Paolo Hospital, Milano, Italy; [3]University of Rome La Sapienza, Rome, Italy; [4]University of Ancona, Ancona, Italy; [5]University of Bologna, Bologna, Italy

Background: Accumulating evidence suggest that inflammatory cytokines produced by monocytes/macrophages play a role in the vascular disease and cognitive decline**.** In HIV patients, herpes virus coinfection has been proposed as a key factor in sustaining immune activation, even in presence of HIV plasma viral control. In our previous study on the ICONA cohort we showed that in HIV patients (pts), CMV infection is an independent risk factor for non AIDS events/deaths.

Methods: We screened all the ICONA pts with an available CMV serology at enrolment (<= 6 months) and a plasma sample after ≥1 year of successful ART (defined as an undetectable HIV viral load and CD4+ count >200/mc). Pts were grouped according to CMV serostatus in CMV-infected (CMV+) (defined as CMV IgG positive) and CMV-uninfected (CMV-). Pts were also matched 2:1 for the following parameters: age, CD4 nadir, duration of HIV infection, HBV and HCV. We excluded pts with previous or current CMV organ diseases and other active organ disease in the previous 5 years. We detected sCD163, TNFα, sCD14, IL-6 using ELISA tests (R&D Systems) on plasma samples. All sample were retested for anti-CMV IgG (GenWay Biotech). Statistical analysis was performed using Mann-Withney Test and Spearman correlation analysis.

Results: A total of 69 subjects were recruited, 46 HIV monoinfected (CMV-) and 23 HIV/CMV (CMV+) coinfected. A higher median of sCD163 level (927.7 vs. 497.8 ng/ml, p=0.018) was found in CMV+ compared to CMV- group. TNFα, sCD14 were also elevated but didn't reach a significant difference in comparison to HIV/CMV- subjects. In HIV/CMV+ subjects a significant correlation was shown between anti-CMV IgG levels and sCD163 (r=0.49, p=0.006) (Fig.1). Moreover only in CMV+ subjects sCD163 levels were related to the duration of HIV infection (r=0.29, p=0.04). In the CMV positive group comparing CMV IgG levels with CD4 count, at the time of sampling, we found a significant negative correlation (r=0.39, p=0.0006).



Conclusions: CMV chronic infection appears to be linked to an increase in sCD163, a markers of myeloid activation, in HIV infected subjects under successful ART with controlled biological (age and sex) and HIV related (HIV suppression, CD4 nadir and CD4 recovery) factors. The persistent activation of monocytes and macrophages that has been implicated in the accelerated development of vascular and neurological disease in general population, may explain the increased risk of non AIDS events found in CMV/HIV coinfected subjects.

304 Genital CMV Shedding Predicts Syphilis Acquisition in HIV-Infected MSM on ART

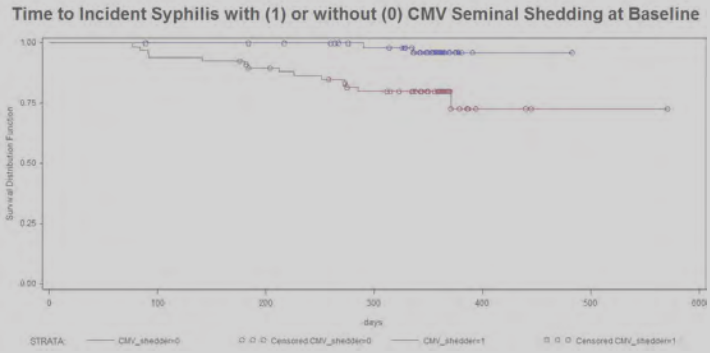
Sara Gianella Weibel[1]; David M. Smith[1]; Eric Daar[2]; Michael Dube[3]; Andrea Lisco[4]; Christophe Vanpouille[5]; Richard Haubrich[1]; Sheldon Morris[1]

[1]University of California San Diego, La Jolla, CA, US; [2]Los Angeles Biomedical Research Institute at Harbor–UCLA Medical Center, Torrance, CA, US; [3]University of Southern California Keck School of Medicine, Los Angeles, CA, US; [4]National Institute of Allergy and Infectious Diseases, Bethesda, MD, US; [5]National Institute of Child Health and Human Development, Bethesda, MD, US

Background: Bacterial sexually transmitted infections (STI) are highly prevalent among HIV-infected men who have sex with men (MSM) and are co-factors in HIV transmission. While sexual behavior and networks are important in STI acquisition, other biological factors have not been emphasized as targets for intervention.

Methods: As part of a behavioral intervention, 136 HIV-infected MSM on suppressive (<500 copies/ml) ART were followed for 12 months and screened for incident bacterial STI (*Neisseria gonorrhoeae*, *Chlamydia trachomatis*, and syphilis*)* every three months. Baseline predictors of bacterial STI were determined using survival analysis of time to incident STI. Tested variables at baseline included: behavioral factors (number of sex partners, number of anal sex acts, use of methamphetamine and other drugs), plasma HIV RNA levels, current and nadir CD4 T and CD8 T cell count, genital shedding of herpes viruses (CMV, EBV, HSV, HHV-6, -7, and -8), serum CMV IgG levels, and soluble markers of genital inflammation (MCP-1, IL-6, TNF-alfa, Interferon-gamma, RANTES and IP-10 in baseline seminal plasma).

Results: Thirty-four subjects (26.2%) acquired bacterial STIs during follow-up, sometimes with more than one pathogen (16 syphilis, 20 gonorrhea, 14 chlamydia). Acquisition of syphilis during follow-up was associated with genital CMV shedding at baseline (21% in CMV shedders versus 3% in non-shedders, P=0.003, see figure attached), younger age (P=0.005) and more sex partners (P=0.047). None of the tested variables except partner number was associated with acquisition of other STIs (chlamydia and gonorrhea at any site). For the acquisition of syphilis, in multivariable Cox-proportional hazard model adjusted hazard rates were as follows: baseline CMV shedding 4.87 (95% CI 1.06-22.47), age 0.96 (per year younger [95% 0.91-1.01]) and number of partners past month 1.06 (per partner per month [0.99-1.13]). Also, syphilis cases compared to non-cases had lower baseline levels of seminal MCP-1 (P=0.01), and lower seminal MCP-1 levels were associated with higher levels of seminal CMV DNA (P=0.005).



Kaplan-Meier Plot showing incidence of Syphilis acquisition in participant with (1) and without (0) CMV seminal shedding at baseline.

Conclusions: In this prospective study, presence of genital CMV shedding at baseline was strongly associated with acquisition of syphilis. Lower level of seminal MCP-1 was associated with both presence of genital CMV shedding and syphilis acquisition. Future studies with anti-CMV therapeutics could help determine underlying mechanisms and if causal associations exist.

392 Defective HIV-1 Proviruses Can Be Transcribed Upon Activation

Ya-Chi Ho; Ross Pollack; Patrick Yong; Robert F. Siliciano

Johns Hopkins University School of Medicine, Baltimore, MD, US

Background: HIV-1 persists in the latent reservoir, primarily resting memory CD4+ T cells, as integrated proviruses. The majority of these proviruses are defective, containing large internal deletions or APOBEC-mediated G-to-A hypermutations. However, we previously found that even if the HIV-1 genome contains lethal mutations, the LTR promoter may remain intact, indicating that HIV-1 RNA may still be transcribed. The transcription of HIV-1 RNAs from defective proviruses may complicate the measurement of the size of the latent reservoir using latency reversing agents during the shock-and-kill strategy, as measurement of the defective proviral RNA does not indicate the reactivation of the clinically significant replication-competent proviruses. Further, whether the cells harboring defective proviruses would expand upon reactivation, or would be eliminated by cytolytic T cells (CTLs), remains unknown.

Methods: Resting CD4+ T cells from aviremic patients under suppressive antiretroviral therapy are activated with CD3/CD28 costimulation under enfurvitide to prevent new rounds of in vitro infection. Autologous CTLs were stimulated with Group M Consensus Gag peptide mixture and IL-2. To examine whether cells containing intact or defective HIV-1 can be eliminated by CTLs, we co-cultured pre-stimulated autologous CTLs with activated CD4+ T cells. Cell-associated RNA and proviral DNA from cells which are resting, activated, and CTL co-cultured was subjected to quantitative PCR and deep-sequencing of the Gag region to examine the start codon of Gag and two tryptophan residues, which are hotspots APOBEC-mediated hypermutations. CTLs were removed by magnetic bead depletion from the CTL-CD4 coculture before qPCR for normalization to CD4 cell count.

Results: We found a significant proportion of the HIV-1 RNA in activated patient CD4+ T cells contains lethal mutations. The amount of defective proviruses increased over the course of activation, indicating expansion of cells containing defective proviruses upon stimulation. The percentage of defective proviruses increased, implying the effect of viral cytopathic effects by reactivated intact proviruses. The amount of HIV-1 proviruses, both intact and defective, decreased after addition of CTLs in some patients, indicating possible elimination by CTLs.

Conclusions: Defective HIV-1 proviruses may be transcribed during latency reversal. Cells containing defective HIV-1 proviruses may expand under T cell activation.

391 Influenza Vaccination Increases HIV-1 Transcription During Antiretroviral Therapy

Christina C. Yek[1]; Sara Gianella[1]; Montserrat Plana[2]; Pedro Castro[2]; Felipe Garcia[2]; Marta Massanella[1]; David M. Smith[1]

[1]*University of California San Diego, San Diego, CA, US;* [2]*University of Barcelona, Barcelona, Spain*

Background: Curative strategies using stimulators such as histone deacetylase inhibitors, disulfiram and IL-7 to reactivate HIV have thus far demonstrated only modest activity. In contrast, transient increases in viremia after administration of standard vaccines have been observed even during antiretroviral therapy (ART). In this study we investigate whether routine influenza vaccination can reactivate HIV.

Methods: Eleven HIV-infected individuals on suppressive ART (<50 copies/ml) were selected from the intervention arm of a randomized trial that studied the effects of a vaccination schedule on viral rebound after structured treatment interruption (NCT00329251). Blood samples were obtained at baseline and 1 month after influenza vaccination. DNA and RNA were extracted from cryopreserved peripheral blood mononuclear cells using a Qiagen AllPrep DNA/RNA Mini Kit. Cell-assoiated HIV DNA and RNA transcripts were quantified by droplet digital PCR using primers for *gag* and 2-LTR (for HIV DNA), unspliced *gag* RNA (HIV usRNA), multispliced *tat-rev* RNA (HIV msRNA), polyA and RPP30 (cellular marker for normalization). Values were adjusted for percentage of CD4 T cells as measured by flow cytometry.

Results: Nine of 11 subjects showed an increase in HIV usRNA after influenza vaccination despite undetectable viral loads throughout. Median HIV usRNA levels pre- and post-vaccination were 28.7 [4.2-56.4] and 91.0 [43.2-173.1] copies/10^6 CD4 T cells, respectively ($p=0.049$). Mean increase in HIV usRNA after vaccination ranged from 0 to 49-fold (mean 10.6). No significant changes were observed in HIV msRNA ($p=0.25$), polyA ($p=0.91$), total HIV DNA ($p=0.15$), or 2-LTR circle copies ($p=0.74$).

Conclusions: This study demonstrated a clear increase in cell-associated HIV usRNA 1 month after influenza vaccination, consistent with antigenic stimulation of the HIV reservoir during suppressive ART. The mean 10.6-fold increase in HIV usRNA is comparable to or better than that seen with administration of Vorinostat. Total HIV DNA and 2-LTR circles did not change, suggesting reactivation of replication-incompetent virus and/or ART-mediated suppression of viral propagation. Although we do not propose that standard vaccinations will cure HIV, these findings suggest that a component of immune stimulation could be considered in the development of eradication strategies.

427 Measurements of Viral Transcription in Elite Suppressor CD4+ T Cells

Christopher W. Pohlmeyer; C. Korin Bullen; Greg Laird; Alyssa R. Martin; Victoria Walker-Sperling; Stanley U. Chioma; Robert F. Siliciano; Joel Blankson

Johns Hopkins University School of Medicine, Baltimore, MD, US

Background: Elite suppressors (ES) are patients who control HIV replication without antiretroviral therapy. Prior studies have shown that the frequency of latently infected cells in these patients is much lower than patients on suppressive antiretroviral regimens. However the frequency of CD4+ T cells that express HIV-1 mRNA at baseline and following T cell stimulation is unknown. In this study we compared HIV-1 transcription levels in CD4+ T cells from chronic progressors (CPs) on suppressive antiretroviral regimens and ES.

Methods: To measure intracellular HIV-1 mRNA, we isolated CD4 T cells from PBMCs of ES and CPs. Replicates of $5x10^6$ cells were stimulated with PMA/ionomycin or DMSO for 24 hours. The cells were collected and lysed in Trizol for RNA extraction and subsequent quantification by qPCR. RNA from supernatants were collected and measured for released HIV-1 mRNA.

Results: A comparison of cell associated HIV-1 mRNA in CD4+ T cells of HAART-suppressed CPs and ES shows that ES have significantly less HIV-1 mRNA per $5x10^6$ cells before stimulation. HIV1 mRNA was uniformly detected in CPs, but was present at very low levels in just 2 of 8 ES ($p>0.05$). When $5x10^6$ CD4+ T cells were stimulated with PMA/ionomycin, the levels of cell-associated HIV-1 mRNA increased in 4 of 7 ES. Additionally, when measuring HIV-1 mRNA levels in culture supernatant following stimulation of 5×10^6 CD4+ T cells with PMA/ionomycin, we detected release of virus from just 2 of 8 ES compared to 5 of 5 CPs. When more replicates were analyzed, viral release was seen in 4 ES. 2 of these patients showed positivity in 1 of 5 replicates ($25x10^6$ cells), releasing approximately 3,000 and 5,000 copies HIV-1 RNA each. Poisson statistics suggests an 89% chance that the signal observed reflects a single cell releasing virus, and our HIV-1 mRNA measurements fit with current estimates of the burst size of an infected CD4+ T cell.

Conclusions: In the present study, we demonstrate that the baseline levels of cell associated HIV-1 mRNA in ES are significantly lower than those observed in CPs per $5x10^6$ cells. However an increase in viral transcription following T cell stimulation was observed. These results further characterize the size of the latent reservoir in ES and confirm earlier studies that suggested that some of these patients are infected with replication-competent virus.

384 Minor Contribution of Host-HIV Readthrough Transcripts to the Level of HIV-1 *gag* RNA

Alexander Pasternak[1]; Una O'Doherty[2]; Ben Berkhout[1]

[1]*Academic Medical Center University of Amsterdam, Amsterdam, Netherlands;* [2]*University of Pennsylvania, Philadelphia, PA, US*

Background: Cell-associated (CA) HIV-1 unspliced RNA is an important marker of the viral reservoir and the response to antiretroviral therapy (ART). Recently it has been used in clinical trials as a measure of virus activation by latency-reversing agents. Primers specific for the HIV *gag* regions are frequently used in PCR-based assays that quantify unspliced RNA. However, because HIV-1 integrates within actively transcribed host genes, it has been suggested that some of the transcripts detected by the *gag*-specific assays may not represent genuine HIV RNA but rather chimeric host-HIV readthrough transcripts. To properly interpret the results of the *gag* assays, it is necessary to determine the relative contribution of such readthrough transcripts to the HIV *gag* RNA in ART-treated patients.

Methods: We developed a sensitive nested real-time PCR assay that amplifies the 5' LTR-encoded U3 – packaging signal region (U3-Psi) of HIV-1. This assay specifically measures host-HIV readthrough transcripts but does not detect genuine HIV-1 unspliced RNA (Fig. 1). Total DNA and total RNA were isolated from PBMC samples of 48 ART-treated patients whose plasma viremia had been undetectable (<40 copies/ml) for ≥1 year prior to the study. CA HIV-1 DNA and RNA were separately quantified in these samples using both the U3-Psi assay and the seminested real-time PCR assay specific for the HIV-1 *gag* region. The sensitivity of both assays is 4 copies/reaction. The same inputs of DNA or RNA were used for both assays.

Results: As expected, both U3-Psi and *gag* assays detected HIV-1 DNA in >90% of the patients (44/48 and 46/48, respectively) with no significant quantitative bias between the assays, demonstrating the functionality of the U3-Psi assay. HIV-1 *gag* RNA was detected in 44/48 of these patients (92%) with the median copy number of 590 (interquartile range, 217-1194) copies/μg total RNA. However, the detectability of readthrough RNA was only 40% (19/48 patients). In the 19 patients where the readthrough RNA was detected, its copy number was 49 (41-122) copies/μg total RNA, representing only 8.3% (2.4%-11.2%) of the HIV-1 *gag* RNA. Notably, the real readthrough/*gag* RNA ratio is much lower, as patients with undetectable readthrough RNA (60% of all patients) were excluded from this calculation.

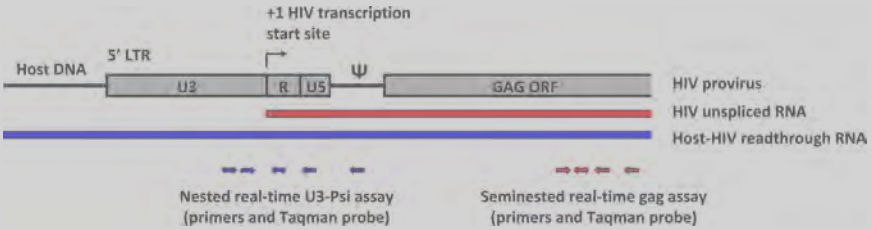


Figure 1. Schematic representation of real-time PCR assays for the detection of readthrough and *gag* RNA. LTR, long terminal repeat; ORF, open reading frame; Ψ, HIV packaging signal (Psi).

Conclusions: We observed only a minor contribution of host-HIV-1 readthrough transcripts to the level of HIV-1 *gag* RNA. The vast majority of HIV-1 *gag* RNA transcripts in ART-treated patients represent genuine HIV-1 unspliced RNA.

379 Characterizing the Active HIV Reservoir on ART: Cell-Associated HIV RNA and Viremia

Feiyu Hong; Elizabeth Fyne; Anthony R. Cillo; Margaret A. Bedison; Dianna Koontz; John W. Mellors

University of Pittsburgh, Pittsburgh, PA, US

Background: Despite combination antiretroviral therapy (ART), HIV-1 RNA can be detected in plasma and peripheral blood mononuclear cells (PBMCs), indicating proviral transcription and production of virions, i.e. an active reservoir of HIV. It is not known whether proviral copy number, HIV-1 transcription, and residual plasma viremia on ART are related.

Methods: We conducted a cross-sectional study of viremic patients off ART and of virologically suppressed (<50 cps/ml) patients on ART. PBMCs were tested for total cell-associated (CA) HIV-1 DNA and unspliced HIV-1 RNA using sensitive qPCR targeting 3' pol. Plasma was tested for residual viremia by single copy assay targeting the same pol region. Unpaired t-test was used to compare viremic and patients on ART. Correlations between plasma viremia and cellular nucleic acids were assessed with Pearson's coefficient.

Results: 12 viremic patients and 23 patients on ART were studied. In patients on ART, median CA HIV-1 DNA was 310 copies/10^6 PBMCs (range: 45, 984) and median CA HIV-1 RNA was 59 copies/10^6 PBMCs (range: 1, 454), both were significantly lower than in viremic patients (median 565 [range: 48, 4680], $p = 0.033$; median 296 [range: 33, 19172], $p = 0.030$; for CA HIV-1 DNA and RNA, respectively). The 5-fold reduction in CA HIV-1 RNA on ART is small compared with the $> 4 \log_{10}$ difference in plasma viremia between these two groups (median 0.44 [range: 0.4, 26] vs. 10542 [range: 564, 474211] copies/mL on and off ART, respectively), indicating substantial persistence of HIV-1 transcription despite ART. A strong, positive correlation was detected between cell-associated HIV-1 DNA and unspliced RNA in both viremic (Pearson's $r = 0.974$; $p < 0.001$) and patients on ART ($r = 0.779$; $p < 0.001$). In viremic patients, the levels of plasma HIV-1 RNA also show strong, positive correlations with cell-associated HIV-1 DNA and RNA (Pearson's $r = 0.849$ and 0.843, respectively; $p < 0.001$). By contrast, in patients on ART, residual plasma viremia was not correlated with cell-associated HIV-1 DNA ($r = 0.06$; $p = 0.78$) or RNA ($r = -0.18$; $p = 0.39$).

Conclusions: This is the first study to show i) a strong, positive correlation between the number of HIV-infected cells and the level of cell-associated HIV-1 RNA in patients on ART, and ii) no correlation between cell-associated HIV-1 RNA and the levels of persistent viremia. These findings suggest that most of persistent HIV-1 transcription in patients on ART does not result in viremia.

390 Nascent LTR-Driven Transcription Can Lead to Translation of HIV Proteins in Resting CD4+ T Cells

Laura DeMaster[1]; Alexander Pasternak[2]; Una O'Doherty[1]

[1]*University of Pennsylvania, Philadelphia, PA, US;* [2]*Academic Medical Center University of Amsterdam, Amsterdam, Netherlands*

Background: We have previously described a model of direct infection of resting CD4+ T cells and contrasted it with models of activated CD4+ T cell infection. We found that infected resting CD4 cells express low levels of viral protein without releasing infectious virus, raising the possibility that reservoirs may express HIV proteins in vivo and be visible to the immune system. Unspliced RNA (usRNA) encoding gag was the predominant HIV RNA form detected in infected resting cells. We designed experiments to ask if nascent transcription occurs in resting CD4+ T cells or if the Gag signal detected is due to an artifact such as read-through transcription or incoming virus.

Methods: To address the contribution of incoming virus to Gag signal, we first sorted Gag+ and Gag-negative cells from cultures infected in vitro and measured levels of HIV DNA in both populations, similar to an approach we used in vivo. RT-PCR and FACS analysis were used to determine whether other viral proteins (made from spliced RNA forms) were present in cells infected in vitro and in CD4+ T cells from ART patients. In addition, given that tat/rev is present at very low levels in vivo in patients on ART, we asked if tat/rev is required for LTR driven expression.

Results: We found that Gag+ cells were strongly (more than 100-fold) enriched for HIV DNA compared to Gag-negative cells in infected cultures. In addition to spliced HIV RNA forms, further evidence of nascent transcription included direct and indirect evidence of new synthesis of multiple HIV proteins by FACS. Read-through transcripts were detectable but present at low levels compared to gag RNA in both cells infected in vitro and in CD4 cells from ART patients. Stimuli such as IL-7 and Romidepsin preferentially induced gag usRNA over read-through transcripts. In contrast, SAHA induced both read-through and gag usRNA transcription two-fold. Notably, we show that low-level protein expression can occur in the absence of tat/rev using a viral vector with a deletion of tat/rev gene expression.

Conclusions: Nascent LTR transcription occurs in HIV-infected resting CD4+ T cells. In vitro and in vivo data suggest that Gag is the predominant transcript (usRNA) and protein expressed in HIV infected individuals on ART. The relative contributions of replication competent and defective proviruses to viral protein expression in vivo remain undefined.

778 Obesity and Inflammation in Resource-Diverse Settings of ART Initiation

Kristine M. Erlandson[1]; Nikhil Gupte[2]; Javier R. Lama[3]; Patcharaphan Sugandhavesa[4]; Thando Mwelase[5]; Ashwin Balagopal[2]; David Asmuth[6]; Thomas B. Campbell[1]; Amita Gupta[2]
On behalf of the A5175 and NWCS319 study team

[1]University of Colorado, Aurora, CO, US; [2]Johns Hopkins University, Baltimore, MD, US; [3]Impacta Peru Clinical Trials Unit, Lima, Peru; [4]Chiang Mai University, Chiang Mai, Thailand; [5]University of Witswatersrand, Johannesburg, South Africa; [6]University of California Davis, Sacramento, CA, US

Background: The heightened inflammatory profile resulting from both HIV infection and obesity is of increasing importance in many HIV-related comorbidities. Little is known about the association between the change in body mass index (BMI) with antiretroviral (ART) initiation and the change in inflammatory markers, particularly in resource-limited settings.

Methods: AIDS Clinical Trials Group study A5175 was a randomized trial comparing 3 ART regimens in resource-diverse international settings; the following is a country stratified random sub-cohort of 270 subjects; 246 subjects had stored samples. BMI (weight [kg]/height [m]^2) was categorized as underweight (UW, <18.5), normal weight (NW, 18.5-24.9), and overweight/obese (OW/OB, ≥25.0). Inflammatory markers were measured (TNF-α, IFN-γ, IL-6, IL-18, IP-10, CRP, sCD14) at weeks 0, 24, 48. Effect of baseline and change in BMI on changes in biomarkers was assessed using random effects models fitted for natural spline at BMI categories and adjusted for age, sex, country, $\log_{10}$ HIV-1 RNA, and treatment arm. A separate model assessed the effect of change to OB BMI (>30 versus ≤30).

Results: Of 246 participants, 50% were female, 53% black, with a median age 35 and CD4 count 179. 37% were assigned to ZDV/3TC+EFV, 33% to ATV+FTC+DDI, and 30% to TDF/FTC+EFV. At week 0, 8% were UW, 65% NW, 27% OW/OB including 7% OB; at week 48, 3% were UW, 60% NW, 37% OW/OB including 9% OB. In multivariate analyses, among baseline UW subjects, an incremental BMI increase was associated with decreased CRP (β -9.32; p=0.001) and trend towards decreased sCD14 (β -0.09; p=0.09). For baseline OW/OB subjects, an increase in BMI was associated with increased sCD14 (β 0.02; p=0.05). No significant associations were detected in the NW group or within other inflammatory markers (p>0.05). In multivariate analyses comparing OB vs not OB participants, OB was associated with an increase in sCD14 (β 0.19; p=0.02) and trend towards higher IL-18 (β 127.7; p=0.056); there were no associations with other markers.

Conclusions: Among HIV-infected persons initiating ART in resource-diverse settings, weight gain among underweight persons may reduce inflammation. In contrast, weight gain among obese persons appeared to heighten inflammation. As sCD14 is a marker of mortality during HIV treatment, the data highlight the potential impact of obesity on treatment outcomes. Further investigation into the impact of obesity on HIV treatment outcomes in resource-limited settings is needed.

779 Body Composition Outcomes at 96 Weeks in the SECOND-LINE RCT DXA Substudy

Mark A. Boyd[1]; Janaki Amin[1]; Patrick W. Mallon[2]; Jennifer F. Hoy[3]; Samuel Ferret[4]; Waldo Belloso[5]; Praphan Phanuphak[6]; Sean Emery[1]; David A. Cooper[1]
SECOND-LINE study group

[1]University of New South Wales Australia, Sydney, Australia; [2]University College Dublin, Dublin, Ireland; [3]Monash University/Alfred Hospital, Melbourne, Australia; [4]Hopital Saint Louis, Paris, France; [5]Hospital Italiano, Buenos Aires, Argentina; [6]Thai Red Cross AIDS Research Centre, Bangkok, Thailand

Background: Antiretroviral therapy (ART) should optimally cause minimal harm. Preferred N(t)RTI-backbones are associated with toxicities with poorly understood long term consequences. In the SECOND-LINE study we demonstrated non-inferiority (margin=12%) of ritonavir-boosted lopinavir (r/LPV) plus raltegravir (RAL-arm) compared to r/LPV plus 2-3N(t)RTI regimen (N(t)RTI-arm) after virological failure of standard NNRTI+2N(t)RTI first-line ART. The RAL-arm was associated with significantly less bone mineral density (BMD) loss. We hypothesised that the RAL-arm would be associated with a greater degree of limb fat gain at 96 weeks.

Methods: We performed a DXA-substudy of SECOND-LINE at weeks 0, 48 and 96 at 8 sites in Argentina, India, Malaysia, South Africa and Thailand. Primary endpoint was the mean percent change from baseline in peripheral limb fat. Analysis was by intention to treat (ITT). We adjusted for baseline imbalances in sex, BMI and smoking. Multivariate linear regression was used to assess between-group differences and predictors of percent change in limb fat mass. Results are mean (SD) and median (IQR).

Results: Baseline characteristics of the 210 enrolled participants: 110 (52%) female, age 38.6 (7.8) years, 52% Asian/43% African, HIV RNA 4.1 (1.0) $\log_{10}$ copies/mL, CD4+ count 220 (167) cells/μL, first-line ART duration 3.3 (1.9-5.9) years, 34%% and 48% on d4T and AZT respectively prior to initiating randomised ART. Eighty six percent and 42% N(t)RTI arm study participants received TDF and AZT respectively. After 96 weeks the mean (SD)% limb fat change from baseline was 16.8 (32.6)% in the N(t)RTI-arm and 28.0 (37.6)% in the RAL-arm, a mean difference (95% CI) of 10.2 (0.1-20.4)% (p=0.048). Baseline predictors of percent changes in limb fat mass over 96 weeks are shown in Table 1.

Table 1. Multivariate baseline predictors of percent change in limb fat mass over 96 weeks

Covariate		Reference	N	Coefficient	95% CI	P-value	Overall p-value
Study arm	RAL-arm	*N(t)RTI-arm*	105	4.9	-2.6, 12.5	0.2	
Sex	Female	*Male*	101	15.0	4.2, 25.9	0.007	
BMI (kg/m^2)			192	1.5	0.5, 2.5	0.005	
BMI change over 96 weeks (kg/m^2)			192	8.4	6.9, 9.8	<0.001	
Baseline limb fat mass (kg)							
	3.9 - 6.9	*0.7 - 3.89*	45	-19.6	-30.8, -8.4	0.001	
	7.0 - 11.0	*0.7 - 3.89*	49	-36.4	-50.0, -22.8	<0.001	
	11.1 - 32.0	*0.7 -3.89*	52	-28.1	-76.8, -41.2	<0.001	<0.001
Ethnicity							
	African	*Asian*	83	-9.8	-19.5, -0.1	0.048	
Total ta-NRTI (AZT/d4T) duration prior to study (years)			192	-4.0	-8.0, 0.02	0.051	

Conclusions: Although N(t)RTI-sparing in SECOND-LINE was associated with improved peripheral limb fat gain over 96 weeks, it was not significant after adjustment for other predictors on multivariate analysis. Significant predictors of peripheral fat gain were female sex, higher baseline BMI and a greater increase in BMI. Africans were more likely to lose limb fat than Asians. Those with more limb fat at baseline were more likely to lose limb fat over 96 weeks. Thymidine-analogue duration prior to study had a borderline association with less peripheral fat gain.

780 Bone Quality by Quantitative Ultrasound at the Radius Does Not Differ in ART-Naïve HIV+ and HIV- Rwandan Women

Eugene Mutimura[1]; Qiuhu Shi[2]; Donald R. Hoover[3]; Kathryn Anastos[4]; Emmanuel Rudakemwa[5]; Jean Claude Dusingize[1]; Jean D'Amour Sinayobye[1]; Michael T Yin[6]

[1]Regional Alliance for Sustainable Development, Kigali, Rwanda; [2]School of Health Sciences and Practice, New York Medical College, New York, NY, US; [3]State University of New Jersey, New Brunswick, NJ, US; [4]Albert Einstein College of Medicine and Montefiore Medical Center, Bronx, NY, US; [5]King Faisal Hospital, Kigali, Rwanda; [6]Columbia University Medical Center, New York, NY, US

Background: Fracture incidence appears to be increased in HIV+ individuals, especially after ART. Dual-energy x-ray absorptiometry (DXA) characterizes bone mineral density (BMD) and is predictive of fracture, but is not widely available in resource-constrained settings (RCS). Quantitative ultrasound (QUS) assesses bone quality by measuring speed of an ultrasound wave (SOS) through bone; lower SOS is predictive of increased fracture risk in older women. We compared bone quality by QUS at the radius in HIV+ and HIV- women in Rwanda.

Methods: Cross sectional study of 646 ART-naïve HIV+ and 211 HIV- women. Demographic, anthropomorphic, laboratory, co-morbidity, and socioeconomic data were collected. A Sunlight Omnisense 7000 QUS (BeamMed Ltd, Israel) was utilized to measure SOS at the radius using 2 trained technicians. Inter-observer agreement assessed on a subset (N=56) was high (kappa>0.90). Mean SOS±SD, T-scores (compared to SOS from young women), Z- scores (compared to SOS from women of same age) using the manufacturer's reference based upon American norms were calculated.

Results: HIV+ women were younger than HIV- women (35±7 vs 42+10 years, p<0.001), had more chronic diarrhea (23% vs 8%, p<0.001), and lower albumin (3.4±0.7 vs. 3.9±0.5 g/dL, p<0.001), but similar body mass index (BMI, 21.5±3.7 vs 21.3±3.8 kg/m^2, p=0.51). Among HIV+ women, mean CD4+ T cell count was 285 (SD=166) cells/mm^3 and 30% had an AIDS defining illness. Average SOS was slightly higher in HIV+ than HIV- women (4024.4±110.5 vs. 4003.9±113.1 m/s, p= 0.02); this group difference was attenuated by adjustment for age (p=0.04) but not BMI (Table). SOS T- and Z-scores did not differ pre or post adjustment for BMI between HIV infection groups. Among HIV+ women, SOS did not differ by CD4+ count <200 vs. ≥200cells/mm^3: 4016±117 vs 4028±107m/s, respectively (p=0.19).

Conclusions: Despite having relatively advanced HIV disease, ART-naïve, predominantly premenopausal Rwandan women did not have worse bone quality by radius QUS than uninfected controls. Our results are consistent with data from a South African study that found that BMD by DXA were similar in ART-naïve HIV+ women and uninfected controls. Unlike DXA, radius QUS is uninfluenced by weight or body fat, is portable, inexpensive, and does not emit radiation or require high-level training. QUS may be an ideal modality to track bone quality and fracture risk after ART-initiation in HIV+ individuals in RCS.

Bone Quality by Quantitative Ultrasound among ART-naïve HIV+ and HIV- Rwandan women

Characteristics	HIV+ (N=646)	HIV- (N=211)	P value	P value Adjusted for Age	P value Adjusted for BMI
Average SOS (m/s)	4024.4±110.5	4003.9±113.1	0.02	0.04	0.02
T score	-0.07±1.37	-0.18±1.43	0.30	-	0.31
Z score	0.09±1.35	0.10±1.38	0.90	-	0.89

Data are presented as Mean±SD; *The p-value is from ANOVA; ART, antiretroviral therapy; HIV+, HIV-infected; HIV, HIV-uninfected; BMI, Body mass index; SOS, ultrasound wave.

Conclusions: Despite having relatively advanced HIV disease, ART-naïve, predominantly premenopausal Rwandan women did not have worse bone quality by radius QUS than uninfected controls. Our results are consistent with data from a South African study that found that BMD by DXA were similar in ART-naïve HIV+ women and uninfected controls. Unlike DXA, radius QUS is uninfluenced by weight or body fat, is portable, inexpensive, and does not emit radiation or require high-level training. QUS may be an ideal modality to track bone quality and fracture risk after ART-initiation in HIV+ individuals in RCS.

781 Predictors and Outcomes of Incident High Cholesterol in Adults on ART in South Africa

Denise Evans[1]; Alana T. Brennan[2]; Faith Moyo[1]; David Spencer[3]; Kay Mahomed[3]; Mhairi Maskew[1]; Lawrence Long[1]; Sydney Rosen[2]; **Matt P. Fox**[2]

[1]University of the Witwatersrand, Johannesburg, South Africa; [2]Boston University, Boston, MA, US; [3]Right to Care, Johannesburg, South Africa

Background: As the HIV-infected population ages in sub-Saharan Africa, non-communicable chronic disease incidence among patients on ART is likely to rise. Specific antiretroviral drugs are considered independent risk factors for cardiovascular disease (CVD), and high total cholesterol (TC) is a risk factor for CVD, stroke and renal disease. We examined predictors of high TC in ART patients in South Africa.

Methods: Prospective study of HIV-positive, ART-naïve adults initiating ART at a large urban clinic in Johannesburg from 04/04 to 07/12. Patients with TC ≥6mg/dl at ART initiation were excluded. We defined incident high cholesterol as a TC ≥6mg/dl and categorized it as (i) one elevated TC, (ii) elevated TC with repeat TC <6mg/dl or (ii) elevated TC with repeat ≥6mg/dl. Cox regression was used to identify variables at ART initiation associated with incident high TC. Person-time started at ART initiation and ended at the earliest of high TC, death, loss to follow up (LTF; >3 months late for next scheduled visit), transfer, completion of 24 months of follow-up, or dataset closure (07/2014).

Results: Among 18,998 eligible patients, 2990 (16%) had a high TC by 24 months on ART. Of these, 488 (16%) had no repeat TC, 1323 (44%) had a repeat TC <6mg/dl, and 1179 (40%) had a persistently high TC ≥6mg/dl. Regression models showed patients ≥40 vs. <40 years, those with a CD4 count <100 vs. ≥100cells/mm^3 or BMI ≥25 vs. <25kg/m^2 at ART initiation had an increased hazard of high TC over the first 24 months on ART (Table).

Of the 2990 patients with a high TC, 5% died, 7% were LTF and 11% developed moderate or severe renal insufficiency (creatinine clearance <60ml/min). Among those with a repeat TC, rates of mortality (0.82 vs. 0.83/100pys) and LTF (6.1 vs. 7.3/100pys) after high TC were similar for those with incident high TC and a repeat TC <6mg/dl compared to those with a persistently high TC ≥6mg/dl. However, those with persistently high TC ≥6mg/dl had a higher rate of renal insufficiency (CrCl <90ml/min) (19.0/100pys) after high TC compared to those who reduced their TC <6mg/dl (16.0/100pys). 31% of patients with a high TC changed a single drug, mainly from d4T to TDF or ABC, while 29% were prescribed cholesterol lowering drugs and 13% had both.

Table 1. Predictors of high total serum cholesterol after 24 months on antiretroviral therapy at Themba Lethu Clinic, Johannesburg, South Africa (n=18,998).

TC Total Cholesterol; NRTI Nucleotide Reverse Transcriptase Inhibitors; NNRTI Non-nucleoside reverse-transcriptase inhibitors; HR Hazard Ratio; CI Confidence interval; d4T stavudine; TDF tenofovir; EFV efavirenz; NVP nevirapine

Conclusions: Older patients, those on stavudine, those overweight or with low CD4 counts should be targeted for frequent TC monitoring and identification of other risk factors of CVD in order to implement lifestyle modifications and pharmaceutical therapy.

782 Metabolic Changes and Second-Line ART in Africa (2LADY/ANRS 12169 Trial)

Amandine Cournil[1]; Assane Diouf[3]; Sabrina Eymard-Duvernay[1]; Adrien Sawadogo[2]; Liliane Ayangma[4]; Louise Fortes-Deguenonvo[3]; Jean-Marc Mben[6]; Eric Delaporte[1]; Laura Ciaffi[1]; Sinata Koulla-Shiro[5]
[1]IRD/UM 1, Montpellier, France; [2]CHU Souro Sanou, Bobo Dioulasso, Burkina Faso; [3]CRCF, Dakar, Senegal; [4]Yaounde Military Hospital, Yaounde, Cameroon; [5]FMSB/University Yaounde 1, Yaounde, Cameroon; [6]ANRS Research Center, Yaounde, Cameroon

Background: Beyond efficacy, information about the impact on metabolism of 2nd line antiretroviral combinations can be of value in the evaluation of long term benefit of treatment in the African context.

The aim was to compare changes over 48 weeks in metabolic profile of three second line regimens within the randomized 2LADY/ANRS 12169 trial (Yaounde, Cameroon; Bobo Dioulasso, Burkina Faso; Dakar, Senegal).

Methods: 451 HIV-1 positive adults, failing standard first line ART were randomized to tenofovir disoproxil fumarate (TDF) + emtricitabine (FTC) + lopinavir/ritonavir (LPV/r) [reference]; abacavir (ABC) + didanosine (ddI) + LPV/r [ABC/ddI] or TDF + FTC + darunavir (DRV) /r [DRV]. Cardiovascular disease (CVD) risk factors considered were obesity or overweight (Body Mass Index (BMI)≥25kg/m²); hypercholesterolemia (≥200mg/dL); hypertriglyceridemia (≥150mg/dL); hypertension (≥130/85mmHg) and metabolic syndrome according to IDF/AHA/NHLBI criteria.

Results: 432 (71% women) patients with a median age of 38 years were analyzed. At entry, the median CD4 count was 183 cells/µl; (IQR: 90-290), 32% were obese or overweight; and 11% had metabolic syndrome with no difference between arms.

The mean weight gain (kg) over 48 weeks was significantly greater in DRV group (+3.0±4.9) than in reference (+0.7±5.2) and in ABC/ddI groups (+0.8±4.7). In DRV group, over 48 weeks 26% of patients increased BMI from normal to overweight or obese.

In contrast, the ABC/ddI compared with DRV group had greater mean increases (mg/dL) in triglycerides (+33±68 vs -6±60; P<0.01) and in cholesterol (+30±53 vs -1±43 ; P<0.001) with significant increases in both HDL- and LDL-cholesterol. Over 48 weeks a significantly higher proportion of patients developed hypercholesterolemia, hypertriglyceridemia and metabolic syndrome in the ABC/ddI compared with DRV group. CVD risk factors did not differ between DRV and reference group.

Lipids levels changes and incidence of metabolic syndrome remained independently associated with treatment regimen in multivariable analyses including baseline clinical and metabolic variables.

Cumulative incidence at week 48	TDF+FTC+LPV/r "Reference" n = 146	ABC+ddI+LPV/r "ABC/ddI" n = 138	TDF+FTC+DRV/r "DRV" n = 148	P
Overweight/obesity	17/106 (16%)	7/84 (8%)	25/97 (26%)	<0.01
Hypercholesterolemia	27/108 (25%)	38/88 (43%)	20/99 (20%)	<0.001
Hypertriglyceridemia	18/125 (14%)	27/112 (24%)	11/125 (9%)	<0.01
Hypertension	11/112 (10%)	14/98 (14%)	13/114 (11%)	0.60
Metabolic syndrome	10/130 (8%)	18/116 (15%)	5/119 (4%)	<0.01

Both efficacy (CROI2014) and metabolic tolerance results at 48 weeks indicate that the recommended WHO regimen remains a valid option.

Conclusions: Despite a marked weight gain with high incidence of overweight and obesity in the DRV group, the most worrying changes in metabolic profile were observed in the ABC/ddI group with important increase in CVD risk factor which could compromise the long term benefit of this combination.

859 Estrogen Replacement in Healthy Postmenopausal Women Reduces %CCR5+ CD4+ T Cells

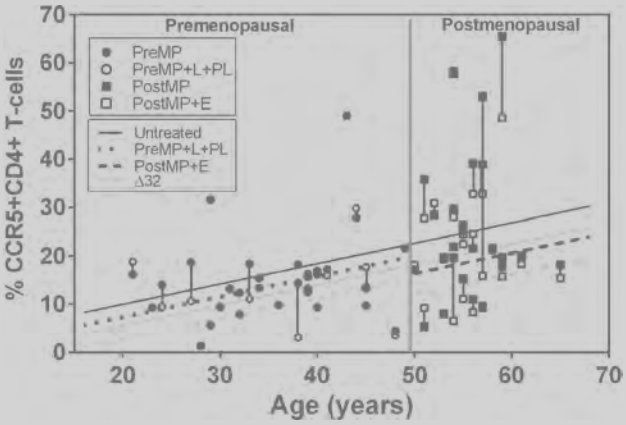
Amie Meditz[1]; Samantha MaWhinney[2]; Kerrie Moreau[2]; Kelsey Melander[2]; Joy Folkvord[2]; Wendy Kohrt[2]; Margaret Wierman[2]; Elizabeth Connick[2]

[1]Boulder Community Health, Boulder, CO, US; [2]University of Colorado Anschutz Medical Campus, Aurora, CO, US

Background: CCR5 is elevated on whole blood and cervical CD4+ T cells of healthy postmenopausal women (postMP) compared to premenopausal women (preMP), suggesting increased risk of HIV acquisition in older women. To test whether estrogen (E) downregulates CCR5, we evaluated CCR5 expression in healthy postMP who received E replacement and preMP who underwent medical induction of menopause.

Methods: Healthy HIV- women were recruited to A) 2 studies of E patch (estradiol 0.05 or 0.075 mg/day) versus placebo (PL) in postMP; B) a study of preMP who underwent menopause induction via GnRH agonist Lupron (L) with add-back E patch (0.075 mg/day) or placebo (PL); and C) an observational study of preMP. Blood was collected from preMP (early follicular phase) and postMP at baseline. Repeat sampling occurred 2 days to 4 weeks following E or PL in postMP and 4 weeks following dosing of L+E or L+PL to preMP. %CCR5+ and %CCR5+HLA-DR+CD38+ (activated) CD3+CD4+ cells were determined by flow cytometry, and CCR5Δ32 genotype by molecular analyses. Data were analyzed using mixed models and nonparametric methods.

Results: In postMP after E, %CCR5+ and %CCR5+activated cells tended to decrease (median Δ, -3.4%; p=0.16, and -5.8%; p=0.28, respectively; n=10). PostMP+PL exhibited small changes in these parameters (median Δ, -0.4%, p=0.10 and -0.8%; p=0.60, respectively; n=15). In preMP, there were statistically nonsignificant decreases after L+PL in %CCR5+ (median Δ, -0.88%, p=0.28; n=11) and %CCR5+activated cells (median Δ, -3.4%, p=0.57; n=9). PreMP who received L+E had median changes of -0.23% (p=0.82; n=9) and 7.4% (p=0.69; n=7), respectively. Across all subjects, after controlling for CCR5Δ32 genotype (p=0.29), there was a 4.2% increase in %CCR5+ (95% CI 1.5%, 6.9%; p=0.003) for every 10-year age increase (Figure). PostMP+E had 6.2% lower %CCR5+ than postMP (95% CI -10.9%, -1.6%; p=0.01). Estimated %CCR5+ tended to be lower in PreMP following L+PL (-2.7%, 95% CI -7.1%, 1.8%; p=0.23), inconsistent with the hypothesis that induction of menopause would substantially increase CCR5 expression. Similar trends were seen in %CCR5+activated cells.



Conclusions: E replacement reduces %CCR5+CD4+ T cells in healthy postMP, suggesting it could decrease HIV acquisition in this group. Lack of a sizeable increase in %CCR5+ in healthy preMP after medically induced menopause may be due to short duration of ovarian hormone suppression, unknown effects of Lupron, or different age-related effects of E on CCR5 expression.

858 CCR5 Expression in HIV-Uninfected Women Receiving Hormonal Contraception

Athe Tsibris[1]; Gaia Sciaranghella[2]; Cuiwei Wang[3]; Kerry Murphy[4]; Zaher Mehri[5]; Ruth M. Greenblatt[6]; Mardge Cohen[7]; Elizabeth Golub[8]; Heather Watts[9]; Mary A. Young[3]

[1]Brigham and Women's Hospital, Harvard Medical School, Cambridge, MA, US; [2]Ragon Institute of MIT, MGH and Harvard, Boston, MA, US; [3]Georgetown University Medical Center, Washington, DC, US; [4]Albert Einstein College of Medicine, Bronx, NY, US; [5]University of Vermont College of Medicine, Burlington, VT, US; [6]University of California San Francisco, San Francisco, CA, US; [7]Stroger Hospital and Rush University and CORE Center, Chicago, IL, US; [8]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [9]The Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD, US

Background: Hormonal contraception may influence a woman's susceptibility to HIV-1 infection. HIV infectivity increases as host receptor and coreceptor expression levels increase. We investigated the effect of hormonal contraception on HIV-1 receptor and coreceptor peripheral blood mononuclear cell (PBMC) expression.

Methods: We used participant samples collected from The Women's Interagency HIV Study (WIHS) between 2004 to 2011 and determined the CD4, CCR5, and CXCR4 expression levels on PBMC from HIV-uninfected women who used depot medroxyprogesterone acetate (DMPA, n=32), the levonorgestrel releasing intrauterine device (LNG-IUD, n=27), or oral contraceptive pills (OCP, n=32). Women who did not use hormonal contraception (n=33) served as a comparator group. Groups were matched by age and race and one sample per participant per group was analyzed. Our monoclonal antibody panels identified monocyte, monocytoid dendritic cell, plasmacytoid dendritic cell, $CD8^+$ T cell, and $CD4^+$ T cell subpopulations. Monocytoid and plasmacytoid dendritic cells were analyzed together as a combined dendritic cell (DC) group. We compared the proportions of cells expressing CD4 and HIV coreceptors.

Results: LNG-IUD users had an increased proportion of $CD4^+$ and $CD8^+$ T cells that expressed CCR5 (4.8 ± 0.4% and 12.5 ± 1.2%, respectively), relative to women on OCP (3.1 ± 0.3% and 8.2 ± 0.7%, $p<0.01$ and $p<0.05$) or no hormonal contraception (3.4 ± 0.3% and 7.6 ± 0.6%, $p<0.05$ and $p<0.01$). LNG-IUD use was associated with a 35% relative increase in the proportion of helper T cells that expressed CCR5 over that observed with the use of OCP and a 29% increase when compared to the use of no hormonal contraception. Increased CCR5 expression was associated with changes on central (T_{CM}) and effector memory (T_{EM}) T cells ($p<0.01$ for all comparisons). Relative increases of 6-12% in the magnitude of cellular T_{CM} and T_{EM} CCR5 expression were observed in the DMPA and LNG-IUD groups, compared to the OCP and no hormonal contraception groups ($p<0.01$ for all comparisons). No differences in the proportion of monocytes or dendritic cells that expressed CCR5, or hormone-associated changes in PBMC CD4 or CXCR4 expression levels, were detected.

Conclusions: The use of the LNG-IUD and, to a lesser extent, DMPA was associated with increased CCR5 expression on peripheral T cells. Comparative work in female reproductive tract tissues and blood is needed to further evaluate contraception-associated increases in CCR5 expression.

860 Progesterone Increases Are Associated With HIV Susceptibility Factors in Women

Alison Y. Swaims[1]; Tammy Evans-Strickfaden[1]; L Davis Lupo[1]; Alfredo Aguirre[2]; Anandi Sheth[2]; Igho Ofotokun[2]; Clyde E. Hart[1]; **Richard E. Haaland**[1]
[1]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US; [2]Emory University School of Medicine, Atlanta, GA, US

Background: Native progesterone and progestin-based hormonal contraception are suspected of increasing women's risk for acquiring sexually transmitted HIV. How progesterone and progestin-based contraceptives affect HIV target cells in women is uncertain. We investigated whether a population of HIV target cells in women, CD4 T lymphocytes, changes cell surface expression of the HIV CCR5 coreceptor, cell activation markers and response stimulation throughout a normal menstrual cycle.

Methods: Peripheral blood mononuclear cells (PBMCs) isolated from 7 women at 5 time points throughout their normal menstrual cycles were tested for expression of the HIV coreceptor CCR5 and the activation marker CD38 using flow cytometry. PBMCs were also stimulated *ex vivo* in the presence of Golgi transport inhibitors and intracellular production of IL-2, IFN-g and TNF-a was detected using flow cytometry. Plasma estradiol and progesterone were measured at each time point using a luminex multiplex assay. A sustained rise in plasma progesterone levels marked the beginning of the luteal phase of the menstrual cycle.

Results: The proportion of CCR5 and CD38 expressing CD4 memory T cells increased from 4% to 7% (p=0.03) from the follicular to luteal phase in 6 of 7 women. The proportion of *ex vivo* stimulated CD4 T cells with detectable intracellular TNF-a increased from 31% to 52% (p=0.006) from the follicular to the luteal phase while production of intracellular IL-2 and IFN-g remained unchanged. Increased populations of TNF-a producing cells were associated with higher plasma progesterone levels (p=0.04). The increase in TNF-a production occurred almost exclusively in cells which were also expressing IL-2 or both IL-2 and IFN-g. Time points with detectable increases in TNF-a production were the same or immediately preceding those where CCR5 and CD38 expression increased in 6 of 7 women. Estradiol levels were not associated with changes in CCR5, CD38, or *ex vivo* cytokine production.

Conclusions: Our results suggest that increases in endogenous progesterone during the luteal phase of the menstrual cycle are associated with HIV target cells that have increased expression of the HIV coreceptor CCR5, higher activation levels, and an increased response to stimulation. Knowing if these progesterone effects exist in the genital mucosa of women could be an important measure for identifying risk factors of progestin-based hormonal contraceptives.

861 Changes in Vaginal Microbiota and Cytokines in HIV-1-Seronegative Women Initiating DMPA

Alison C. Roxby[1]; David N. Fredricks[2]; Katherine Odem-Davis[1]; Kristjana H. Ásbjörnsdóttir[1]; Linnet Masese[1]; Tina L. Fiedler[2]; Walter Jaoko[3]; James N. Kiarie[3]; Julie M. Overbaugh[2]; R Scott McClelland[1]
[1]University of Washington, Seattle, WA, US; [2]Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US; [3]University of Nairobi, Nairobi, Kenya

Background: Depot-medroxyprogesterone acetate (DMPA) has been associated with HIV acquisition in African women. We studied changes in vaginal microbiota and inflammatory milieu after DMPA initiation, a mechanism through which DMPA may modify HIV susceptibility.

Methods: In a prospective cohort study of high-risk Kenyan women, we collected monthly vaginal swabs over 1 year pre- and post-DMPA to evaluate microbiota and immune mediators. All women initiating DMPA were included. Using quantitative PCR with specific bacterial primers, we measured quantities of *Lactobacillus crispatus, L. jensenii, L. iners*, *Gardnerella vaginalis*, and total bacterial load (16S rRNA gene levels) on vaginal swabs. Six vaginal immune mediators were measured with ELISA. Trends in detection and quantity of bacteria were estimated by logistic and linear mixed-effects regression models; cytokine trends associated with DMPA use were estimated using tobit random-effects regression.

Results: From 2010-2012, 15 HIV-seronegative women initiated DMPA, contributing 85 visits (median 6 visits/woman (range 3-8)). The median time of DMPA-exposed follow-up was 8.4 months (range 1.5-11.6). Seven women (46%) had bacterial vaginosis (BV) within 70 days before DMPA start. *L. iners* was detected in 13 women (87%) prior to DMPA start, but other lactobacilli were rarely detected. *G. vaginalis,* present in all women pre-DMPA, declined by 0.21 $\log_{10}$ copies/swab per month after DMPA exposure (p=0.011). Total vaginal bacterial load declined by 0.08 $\log_{10}$ copies/swab per month of DMPA use (p=0.017). Sustained declines in quantities of interleukin (IL)-6 (p=0.025), IL-8 (p=0.041) and IL-1 receptor antagonist (p<0.001) were noted after starting DMPA. Nine women (60%) had *L. crispatus* detected after DMPA start; *L. crispatus* detection was significantly correlated with lower levels of IL-6 and IL-8 (p=0.009, p=0.02 respectively). No decrease in BV, vaginal pH or discharge was seen after DMPA start. Declines in *G. vaginalis* and immune mediators were preserved after adjustment for sexual behavior, condom use, BV, antibiotic use and vaginal washing.

Conclusions: Initiation of DMPA led to sustained shifts in vaginal bacterial concentrations and levels of inflammatory mediators. We adjusted for likely behavioral and biological confounders, providing greater evidence that changes seen may be strongly related to DMPA. Further studies are warranted to outline specific components of the vaginal microbiota influenced by DMPA use, and the impact on HIV susceptibility.

1086 Mobile VMMC Teams in Tanzania See Older Clients and Have Higher Followup Rates

Augustino M. Hellar[1]; Dorica Boyee[1]; Hally Mahler[1]; Marya Plotkin[1]; Touma Ng'wanakilala[1]; Kelly Curran[2]; Tigistu Ashengo[2]; Hawa Mziray[1]; Erick Mlanga[3]; Sifuni Koshuma[4]
[1]Jhpiego, Dar es Salaam, United Republic of Tanzania; [2]Jhpiego, Baltimore, MD, US; [3]US Agency for International Development, Dar es Salaam, United Republic of Tanzania; [4]Ministry of Health and Social Welfare, Iringa, United Republic of Tanzania

Background: Tanzania has rolled out Voluntary Medical Male Circumcision (VMMC) since 2009 in 12 priority regions with high HIV and low male circumcision rates. More than 390,000 clients have been served in Iringa, Njombe and Tabora regions with support from Jhpiego and USAID. Nearly 80% of clients reached are aged 10-19 years. Iringa and Njombe are approaching their original 80% coverage target. Service delivery modalities include routine, in which services are delivered in larger health facilities, typically at low volume, and campaigns where teams of providers move into new communities and do 1-3 week bursts of intense, high-volume provision of services. In May 2014, mobile services were introduced specifically to serve the hard-to-reach clients not reached by other modalities. This roving team of providers, move along villages to provide VMMC services even in non-facility settings. The analysis presents findings on differences in the three modalities.

Methods: Secondary data review was conducted on 148,880 individual records, stripped-of identifiers from all three regions from October 2013-August 2014, the year when mobile teams were introduced. Records were broken into three modalities: campaign, routine and mobile. Frequencies were compared between the modalities and Chi^2 was used to test for the significance of the differences.

Results: 76% of the 148,880clients circumcised during the year were aged <20 years. Mobile teams reached older clients compared to other service delivery modalities (p<0.001), as shown below.

Overall HIV testing uptake was high (97%) regardless of the modality. A higher proportion tested HIV positive in the routine followed by mobile modalities (2.1% and 1.4% respectively). Follow-up rates were significantly higher in the mobile modality both for 1st and 2nd visits (91.7% and 63.1% respectively) compared to static modality (70% and 36% respectively); p-value < 0.001).

Service Modality	No. of clients served	% of clients < 20 years	% of Clients ≥ 20 years
Campaign	132,080	78%	22%
Routine	11,392	71%	29%
Mobile	5,408	62%	38%
Total	148,880	76%	24%

Conclusions: A higher proportion of older clients (20 years or older) accessed VMMC services through mobile teams compared to other modalities. Mobile teams are circumcising in lower volume settings than campaigns where it's easier to offer more privacy to older clients. Introduction of mobile teams could be an efficient strategy to attract older clients who have not previously accessed services. With the slightly high proportion of HIV positive clients, linkage to care and treatment must be ensured. Follow-up rates were very high in the mobile setting, probably because of active client follow-up.

1087 High Acceptability of PrePex™ Device in Routine Programmatic Settings in Rwanda

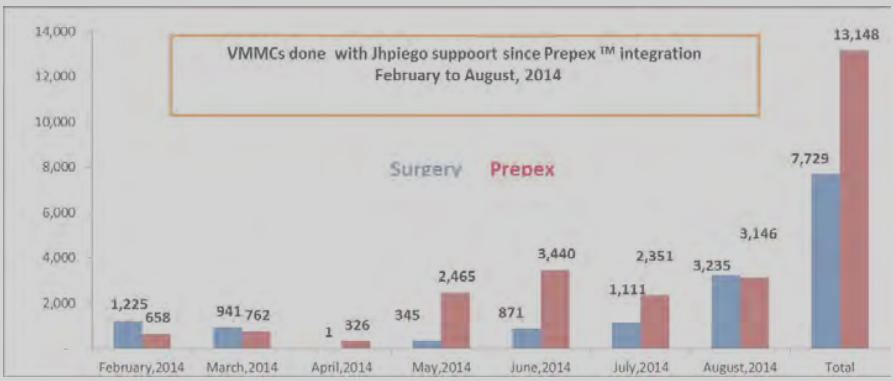
Eugene Rugwizangoga[1]; Beata Mukarugwiro[1]; Jovite Sinzahera[1]; Alphonse Mutabaruka[1]; Gloriose Abayisenga[1]; J.D. Ntakakirabose[1]; Ngeruka Leon[4]; Eugene Zimulinda[3]; Kelly Curran[2]; Tigistu Ashengo[2]

[1]Jhpiego/Rwanda, Kigali, Rwanda; [2]Jhpiego, an Affiliate of Johns Hopkins University, Washington, DC, US; [3]US Department of Defense, Rwanda, Kigali, Rwanda; [4]Rwanda Military Hospital, Kigali, Rwanda

Background: The PrePex™ device offers an alternative to conventional surgical methods of male circumcision. Because it does not require injectable anesthesia or the cutting of vital tissue, PrePex™ requires less surgical capacity and may be more acceptable to men, potentially increasing uptake of this proven HIV prevention intervention. In May 2013, PrePex™ received WHO prequalification for adults aged 18 and above. Rwanda was the first country to conduct PrePex™ safety and acceptability studies and is now the first to scale-up PrePex™ in programmatic settings. PrePex™ currently comes in five adult sizes, A through E. Since 2009, Jhpiego, with PEPFAR funding through the US Department of Defense, has supported the Rwanda Defense Force (RDF) to provide VMMC to soldiers, their dependents and civilians living near base clinics. Since February 2014 PrePex™ has been offered alongside conventional surgery to adult VMMC clients at Jhpiego-supported RDF sites.

Methods: We reviewed routine program data from Jhpiego-supported RDF sites from program inception in October 2009 through August 2014.

Results: Between October 2009 and August 2014 86,284 adolescent boys and adult men were circumcised at Jhpiego-supported RDF sites, with 20,877 of these clients served in the seven months since PrePex™ was added. Since PrePex™ was introduced nearly two thirds of circumcisions have used the device, with 13,148 (63%) of clients receiving PrePex™ and 7,729 (37%) conventional surgery. Overall uptake has been increasing year to year; the number of clients served doubled from 2012 to 2013 thanks to efficiency approaches such as task shifting to nurses and use of mobile (outreach) teams. PrePex™ introduction appears to have accelerated this trend although in July 2014 the program experienced device stockouts especially in sizes A,D and E.



PrePex™ and Surgical VMMCs Conducted at Jhpiego-supported RDF Sites, Feb-Aug 2014

Conclusions: The introduction of the PrePex™ device in routine programmatic settings is well accepted by adult VMMC clients in Rwanda, with 63% of this age group choosing PrePex™. The acceptance rate would have likely have been higher if not for a stock out of PrePex™ devices beginning in July 2014. Programs planning to scale up PrePex™ should anticipate the supply chain implications of this device which is currently available in five adult sizes.

1089 Potential Protection From HIV Transmission by Penile Cuttings in Papua New Guinea

Ivy H. Shih[1]; Lester Asugeni[2]; Matthew David[5]; Paul Horwood[5]; Parana Hewage Mangalasir[3]; David Mc Laren[3]; Rachael Tommbe[2]; Andrew Vallely[1]; Arnold Waine[4]; Stuart G. Turville[1]

[1]The Kirby Institute, Sydney, Australia; [2]Pacific Adventist University, Port Moresby, Papua New Guinea; [3]James Cook University, Cairns, Australia; [4]University of Papua New Guinea, Port Moresby, Papua New Guinea; [5]Papua New Guinea Institute of Medical Health, Goroka, Papua New Guinea

Background: Male circumcision reduces HIV acquisition by 66% but there has yet to be a scientific consensus on the protective mechanism. Current hypotheses implicate the inner foreskin due to a thinner primary barrier and greater target cell density. Unique to Papua New Guinea (PNG), ethnographic studies documented widespread non-medical penile cutting practices. The dorsal slit (DS) is the most common and leads to exposure of glans and inner foreskin and provides an opportunity to study a scenario where the inner foreskin is exposed but not removed. We present results from a cohort study assessing histological changes to thin skin that may aid prevention in both circumcised and dorsal slit men.

Methods: Foreskin samples were obtained from men with or without existing DS following elective enrolment at a free circumcision service offered at Port Moresby, PNG. Histological evaluation on frozen and paraffin embedded foreskin sections assessed primary barrier parameters that potentially afford HIV protection. Phenotypes were measured on hematoxylin and eosin stained sections: Stratum corneum thickness (SC), epithelial surface area (SA) and epithelial adhesion to the dermis, the latter two used to evaluate foreskin fragility. Alkaline expansion was conducted to representatively measure SC architecture. Imaging with a high- resolution slide scanner generated an entire tissue section image and epithelium SA was quantified with a recognition algorithm. Density and distribution of HIV target cells foreskin tissue was determined by immunofluorescence to establish foreskin vulnerability.

Results: Men with DS had significantly thicker SC in their inner foreskin than uncircumcised men: 12.09um±2.92 versus 9.87um±2.54 respectively (n=16; p<0.001; 500 total measurements). In DS individuals, the inner and outer foreskin epithelium SA collectively showed significant difference (outer: 0.0457±0.0108mm^2; inner:0.0285±0.0078mm^2) (p<0.001; 160 total measurements)). This observation was shared with epithelium-dermis adhesion (outer: 2.4583±0.7891;inner: 1.7878±0.5510) (p<0.01). CD4 T cells were also observed in the inner and outer foreskin.

Conclusions: The DS confers a degree of protection due to the inner foreskin SC thickening similar to the protective thick skin SC phenotype of outer foreskin. Beyond the protective primary barrier, the increased fragility of the inner foreskin in comparison to outer foreskin presents a new parameter that may account for the inner foreskin being a more vulnerable area.

1084 HSV-2 Shedding From Male Circumcision Wounds Among HIV-Infected Men

Mary K. Grabowski[1]; Godfrey Kigozi[2]; Ronald H. Gray[1]; Jordyn L. Manucci[3]; David Serwadda[4]; Eshan U. Patel[3]; Fred Nalugoda[2]; Maria J. Wawer[1]; Thomas C. Quinn[5]; Aaron A. Tobian[3]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [2]Rakai Health Sciences Program, Kalisizo, Uganda; [3]Johns Hopkins University School of Medicine, Baltimore, MD, US; [4]Makerere University College of Health Sciences, Kampala, Uganda; [5]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD, US

Background: A randomized trial showed that although medical male circumcision (MMC) reduces herpes simplex virus type 2 (HSV-2) acquisition among men, MMC had no impact on HSV-2 transmission to female partners. We conducted a prospective observational study in Rakai, Uganda to assess HSV-2 shedding post-MMC.

Methods: HSV-2 shedding was evaluated among 176 HIV and HSV-2 co-infected men (145 self-reported antiretroviral therapy (ART)-naïve, 9 self-reported ART use with detectable plasma viral load (VL), and 22 self-reported ART with undetectable plasma VL of <400 copies/mL). All men underwent dorsal slit MMC. HSV-2 serostatus was determined by an HSV-2 ELISA (Kalon Biological Ltd, Guilford, UK) with positive serology defined as an optical density index value ≥ 1.5. Preoperative and weekly penile lavages for 6 weeks were tested for HSV-2 shedding and viral load using a real-time quantitative PCR assay with primers to glycoprotein B. HSV-2 shedding was defined as >50 copies of HSV-2 DNA/mL on two separate runs. Prevalence risk ratios (PRRs) and 95%CI were estimated using Poisson regression with generalized estimating equations and robust variance.

Results: HSV-2 shedding was detected in 9.7% (17/176) of men prior to MMC. There was a non-significant increase in the proportion of men with post-MMC HSV-2 shedding relative to baseline at weeks one (12.9%, 22/170, PRR=1.33, 95%CI=0.74-2.38, p=0.329) and two (14.8%, 23/155, PRR=1.50, 95%CI=0.86-2.38, p=0.153). HSV-2 shedding returned to baseline levels by week six after MMC (6.9%, 10/144, PRR=0.71, 95%CI=0.36-1.41, p=0.330). Post-operative HSV-2 shedding did not differ significantly between men who reported ART use compared to those who did not report ART use (PRR=0.67, 95%CI=0.24-1.80). HSV-2 shedding was lower among men with MMC wounds that were certified as healed (PRR=0.61, 95%CI=0.36-1.06, p=0.082). Among men with detectable HSV-2 shedding, the median HSV-2 $\log_{10}$VL/mL was elevated at week one (median=3.2, IQR=2.2-4.8) compared to baseline (median=2.3, IQR=1.8-2.9), though this difference was not statistically significant (p=0.09.) Levels of HSV-2 among men with detectable shedding were similar to baseline at all other post-operative visits.

Conclusions: Penile HSV-2 shedding was non-significantly increased during the first two weeks after MMC. Men undergoing MMC should be counseled on sexual abstinence until wound healing and consistent condom use thereafter.

1088 Self-Selection of Circumcision Acceptors, Risk Compensation and Effectiveness of Circumcision Among Service Recipients, Rakai, Uganda

Joseph Kagaayi[1]; Xiangrong Kong[2]; Godfrey Kigozi[1]; Fred Nalugoda[1]; Steven J. Reynolds[3]; David Serwadda[4]; Nelson K. Sewankambo[5]; Maria J. Wawer[2]; Ronald H. Gray[2]

[1]Rakai Health Sciences Program, Entebbe, Uganda; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [3]Division of Intramural Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, US; [4]Makerere University School of Public Health, Kampala, Uganda; [5]Makerere University College of Health Sciences, Kampala, Uganda

Background: There are limited data on characteristics of acceptors of safe male circumcision (SMC), risk compensation and effectiveness of SMC service programs. We compared baseline characteristics of SMC acceptors and non-acceptors, determined the effectiveness of SMC and compared trends in sexual behaviors of the two groups using data on men aged 15-49 years enrolled in the Rakai community cohort study in Uganda.

Methods: 1192 non-Muslim HIV-negative SMC acceptors were compared to a stratified random sample of 2384 uncircumcised men. Baseline behaviors and trends over time were compared using multivariable modified Poisson with generalized estimating equations. HIV incidence rates between the groups were compared using the incidence rate ratio (IRR) from a multivariable Poisson regression model.

Results: Overall SMC acceptors were younger, less likely to be currently or previously married, and had higher education attainment. Among sexually active men, baseline sexual behaviors were comparable between the groups. However SMC acceptors had 26 percent higher prevalence of genital ulcers compared to non-acceptors (p=0.025). After circumcision, the rate of increase in prevalence of sexual activity was 2.6 percent higher among SMC acceptors (p<0.001) compared to non-acceptors. On stratification by age, the difference was 3.2 percent higher, p=0.08 among youths (15-24) but no difference was seen above 24 years. The prevalence of sexual activity with women in higher risk occupations (bar attendants, alcohol brewers, restaurant workers, itinerant traders, fisher folk, housemaids), increased by 10.2 percent per year among SMC acceptors (p=0.007) but no change occurred among uncircumcised men. Trends in other sexual behaviors were similar between the groups. HIV incidence among SMC acceptors was 0.61/100 person years and 1.11/ 100 person years among non-acceptors (adj. IRR=0.50, p=0.05, 95 percent CI=0.25-1.01).

Conclusions: The higher prevalence of genital ulcers among sexually active SMC acceptors suggests that higher risk sexually active men self-selected to receive SMC. The suggestion of faster increase in sexual activity among circumcised youths and the increase in partnerships with higher risk women suggest possible behavioral disinhibition and need to be investigated in other settings. Though these behaviors, did not attenuate the effectiveness of SMC, there is need to add avoidance of high risk partners to the current SMC messaging.

NeuroAIDS Pathogenesis and Antiretroviral Therapy

56 Randomized Clinical Trial of Antiretroviral Therapy for Prevention of HAND

Fujie Zhang[1]; Robert Heaton[2]; Hao Wu[3]; Hua Jin[2]; Hongxin Zhao[4]; Xin Yu[5]; Donald Franklin[2]; Weiwei Mu[1]; Florin Vaida[2]; **Scott Letendre**[2]

[1]Chinese Center for Disease Control and Prevention, Beijing, China; [2]University of California San Diego (UCSD), San Diego, CA, US; [3]Capital Medical University, Beijing You'an Hospital, Beijing, China; [4]Capital Medical University Beijing Ditan Hospital, Beijing, China; [5]Peking University, Beijing, China

Background: Neurocognitive (NC) impairment (NCI) is common among treated HIV+ adults and can occur for several reasons, including production of viral proteins in the CNS, neuroinflammation, and antiretroviral therapy (ART) neurotoxicity. To date, clinical trials have focused on treatment of existing NCI and have been largely inconclusive. We conducted a clinical trial to determine whether one ART regimen would better prevent NCI than another.

Methods: 250 HIV+, ART-naive adults were randomized to either open-label zidovudine-lamivudine-nevirapine (ZLN) or tenofovir-lamivudine-efavirenz (TLE) at two hospitals in Beijing. All subjects were NC normal and had CD4+ T-cell counts below 350/mm^3 at entry. Subjects were followed for 96 weeks with comprehensive NC testing and safety assessments. NC performance was adjusted for local normative data and summarized by the Global Deficit Score (GDS) and by the proportion of subjects who developed incident NCI. NC change was summarized using a regression-based summary change score (SCS). Intent-to-treat completer (ITT-C, n=239) and as-treated (AT, n=189) analyses were performed.

Results: The treatment groups had similar demographic and disease characteristics, including plasma HIV RNA (mean 4.2 $\log_{10}$ copies(c)/mL in both groups) and CD4+ T-cell counts (mean 235.1 (ZLN) vs. 222.1 (TLE), p=0.32). GDS values at entry were also similar (mean 0.12 (ZLN) vs. 0.14 (TLE), p=0.15). A high proportion of subjects attained virologic suppression: 92% had plasma HIV RNA below 50 c/mL in both groups at 48 weeks (p=.65, ITT-C). TLE was associated with greater risk of incident NCI over 96 weeks than ZLN in either ITT-C (p=.009) or AT (p=0.037) analyses. Consistent with this finding, the SCS also differed between the groups at 96 weeks (ITT-C: d=.27, p=0.016; AT: d=.28, p=0.034). Safety assessments identified that 73/128 (57.0%) subjects in the ZLN group had at least one adverse event compared with 42/122 (34.4%) in the TLE group, leading to greater discontinuation of study drugs in the ZLN group (38% vs. 2%, p<.001). The most common adverse events were liver toxicity and bone marrow suppression.

Conclusions: This is the first randomized clinical trial to demonstrate that ART regimens differ in preventing NC decline using comprehensive NC testing. Possible explanations include differences between the regimens in drug distribution into the CNS and neurotoxicity. The substantial difference in other adverse events dictates additional research to identify a less toxic alternative to ZLN.

57 Neurocognitive Function in Africans Failing First-Line ART and Responses to Second Line

Andrew D. Kambugu[1]; Jennifer Thompson[2]; James Hakim[6]; Dinah Tumukunde[10]; Joep van Oosterhout[7]; Anne Hoppe[2]; Charles Kwobah[9]; Sarah Walker[2]; Nicholas Paton[8]
On behalf of the EARNEST Trial Team

[1]Infectious Diseases Institute, Makerere University Kampala, Kampala, Uganda; [2]University College London, London, United Kingdom; [3]Joint Clinical research Centre, Kampala, Uganda; [4]Queen Elizabeth Central Hospital, Malawi, Blantyre, Malawi; [5]AMPATH, Kenya, Eldoret, Kenya; [6]University of Zimbabwe, Harare, Zimbabwe; [7]Dignitas International, Zomba, Malawi; [8]National University of Singapore, Singapore, Singapore; [9]Moi University College of Health Sciences, Eldoret, Kenya; [10]Joint Clinical Research Centre, Kampala, Uganda

Background: Neurocognitive impairment is an important co-morbidity in HIV infection. Data describing neurocognitive function in patients from sub-Saharan Africa are generally sparse, with only limited data describing neurocognitive function at the time of failure of first-line therapy, and none describing the changes in neurocognitive function in response to second-line therapy.

Methods: We studied patients who were enrolled in EARNEST, a large multi-centre trial of second-line therapy conducted at 14 sites in sub-Saharan Africa. Eligible patients were >12 years old and failing first-line therapy according to WHO criteria after >12 months on an NNRTI-based regimen. Patients were randomised to take second-line therapy (open-label) with lopinavir/ritonavir (400mg/100mg twice daily) plus either 2-3 clinician-selected NRTIs, raltegravir, or as monotherapy after 12 weeks' induction with raltegravir. Neurocognitive function was tested on those aged >18 years at baseline (switch to second-line), weeks 48 and 96 using colour trails tests 1 and 2, and the grooved pegboard test. Test results were converted to a composite z-score using US test norms.

Results: 1036 patients (>86% of those >18 y enrolled in the trial) had evaluable tests at baseline, and 915 patients at week 96. Patients were 58% female, mean age 38 years, median viral load 65,000 c/ml, median CD4 count 73 cells/mm3 at first-line failure. Mean (SD) composite z-score at baseline was -2.96 ± 1.74; z-scores were independently lower in older individuals, and those with lower body weight, higher viral load, lower haemoglobin, fewer years of education, fewer working hours per week, previous CNS disease, or taking fluconazole (all P<0.05 in a multivariable model). Neurocognitive function improved markedly after starting second-line therapy (mean (SE) increase in Z-score of +1.23 (0.04) at week 96), with no difference between the arms (P=0.35; Figure 1).

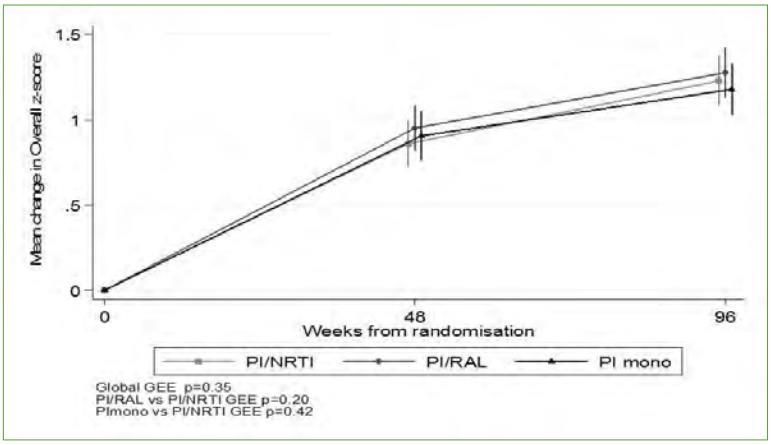

Figure 1: Changes in z-score over 96 weeks in the three randomised groups

Conclusions: Patients in sub-Saharan Africa failing first-line therapy appear to have severely impaired neurocognitive function. In part this may reflect inadequate data for normalization, but the relationship with high viral load and indicators of general debility suggest much of the impairment is HIV-related. Neurocognitive function improves markedly on second-line therapy. The lack of difference between standardised treatment regimens with very different CNS penetration indicates that this need not be a primary consideration in the choice of an optimal drug regimen for second-line therapy.

58 Compartmentalized HIV Rebound in the CNS After ART Interruption

Sara Gianella Weibel; Michelli Faria de Oliveira; Konrad Scheffler; Matt Strain; Antonio De la Torre; Scott Letendre; David M. Smith; Sergei L. Kosakovsky Pond; Ronald J. Ellis
University of California San Diego, La Jolla, CA, US

Background: If strategies currently in development succeed in eradicating HIV reservoirs in peripheral blood and lymphoid tissues, residual sources of virus may remain in anatomic compartments, including the central nervous system (CNS). To design effective eradication strategies, it is crucial to determine to what extent compartmentalized HIV reservoirs contribute to viral rebound after antiretroviral therapy (ART) interruption

Methods: Paired blood and cerebrospinal fluid (CSF) samples were collected from 14 chronically HIV-infected individuals undergoing ART interruption. At the first two available time-points following viral rebound, we sequenced HIV-1 *env* (*C2-V3*), *gag (p24),* and *pol (*reverse transcriptase) regions amplified from cell-free HIV RNA in blood and CSF using

the Roche 454 FLX Titanium platform. Analyses of viral genetic compartmentalization and evolution in CNS and blood were used to identify the likely source compartment (blood or CSF, with the latter representing the CNS anatomical compartment) of HIV RNA rebound following ART interruption. At the same time-points, we measured levels of different soluble markers of inflammation and cellular trafficking (i.e. soluble [s]CD14, sCD163, IL-2, IL-6, IL-8, TNF-α, IL-10, MCP-1 and MIP-1α in blood and CSF).

Results: In ten out of 14 participants viral rebound populations were compartmentalized between blood and CSF (F_{st}, $p \leq 0.05$ for at least one gene). Seven participants were sampled within three weeks of the first detectable HIV RNA in CSF, suggesting that rebound originated within CNS rather than migrating from blood. At the second sampled time-point, three additional participants became compartmentalized. Only one participant remained panmictic (genetically mixed populations) for the entire study follow-up. Levels of four cytokines (IL-2, IL-6, sCD163 in blood and TNF-α in CSF) were higher in non-compartmentalized participants ($p \leq 0.05$), but none was significant after adjusting for multiple testing.

Conclusions: Our study suggests that HIV reservoirs in the CNS contribute to viral rebound in most HIV-infected subjects interrupting ART. Reservoirs in all anatomic compartments need to be actively targeted to achieve a complete functional cure.

59 Impaired Blood-Brain Barrier Integrity Is Associated With Neuronal Injury in HIV

Birgitta Anesten[1]; Lars Hagberg[1]; Henrik Zetterberg[2]; Staffan Nilsson[3]; Bruce J. Brew[4]; Dietmar Fuchs[5]; Richard Price[6]; Magnus Gisslén[1]

[1]University of Gothenburg, Gothenburg, Sweden; [2]University of Gothenburg, Gothenburg, Sweden; [3]Mathematical Sciences, Chalmers University of Technology, Gothenburg, Sweden, Gothenburg, Sweden; [4]University of New South Wales, Sydney, Australia; [5]Division of Biological Chemistry, Biocenter, Medical University, Innsbruck, Austria, Inssbruck, Austria; [6]University of California San Francisco, San Francisco, CA, US

Background: Blood-brain barrier (BBB) damage is prevalent in HIV. The aim of this study was to assess the prevalence of BBB disruption in different stages of HIV-infection and study risk factors and potential association with neuronal injury.

Methods: Using a cross-sectional design and archived CSF samples from three cohorts (Gothenburg, Sweden; San Francisco, USA; Sydney, Australia), we compared BBB integrity (CSF/plasma albumin ratio) with CSF and blood concentrations of HIV RNA and neopterin, CSF WBC count, and CSF neurofilament light protein (NFL) in 7 HIV-infected groups (n=657): 4 groups of untreated 'neuroasymtpomatic' (NA) subjects defined by blood CD4+ T cells of >350, 200-349, 50-199, and <50 cells/μL; 2 groups of untreated patients with HIV-associated dementia (HAD) staged by severity (stage 1 vs 2-4); subjects on antiretroviral treatment (ART) with P HIV-RNA <50 copies/mL >6 months. An HIV-uninfected control group was also examined (n=53).

Results: The albumin ratio was significantly increased in HAD as compared to all other groups with highest levels in those with more severe dementia. 68 % of patients with HAD had increased albumin ratio compared to 16 % of NA subjects without ART. No significant difference in albumin ratio was found between NA untreated subjects, subjects on ART, and HIV-negative controls. Significant correlations between BBB integrity and CSF WBC count ($p<0.01$, $r_s=0.16$), CSF HIV RNA levels ($p<0.01$, $r_s=0.14$), blood ($r_s=0.20$) and CSF ($r_s=0.25$) neopterin, and age ($r_s=0.24$; all $p<0.001$) were found in NA untreated subjects. In a multiple linear regression analysis only age and CSF neopterin stood out as independent predictors to albumin ratio with adjusted estimates in the multivariate analysis. Furthermore, a significant correlation was found between albumin ratios and CSF NFL concentrations in untreated patients ($p<0.001$, $r_s=0.40$) as wells as in patients on ART ($p<0.001$, $r_s=0.57$). Albumin ratio was confirmed as an independent predictor of CSF NFL together with age, CD4 and CSF WBC count.

Conclusions: BBB disruption is mainly found in patients with HAD. Neither untreated neuroasymtpomatic subjects, nor patients on antiretroviral treatment had albumin ratios that were significantly different from HIV-negative controls. Intrathecal immunoactivation is a risk factor of BBB impairment and the association with CSF NFL suggest a pathogenic pathway between inflammation, BBB disruption and neural injury before development of dementia.

60 Cortical and Subcortical Brain Volumes in Primary HIV Infection

Patrick W. Wright[1]; Ashmit Pyakurel[3]; Kevin Robertson[4]; Julia Peterson[5]; Henrik Zetterberg[7]; Dietmar Fuchs[6]; Richard Price[5]; Dieter Meyerhoff[5]; Serena Spudich[2]; Beau Ances[1]

[1]Washington University School of Medicine, Saint Louis, MO, US; [2]Yale University School of Medicine, New Haven, CT, US; [3]Louisiana Tech University, Ruston, LA, US; [4]University of North Carolina, Chapel Hill, NC, US; [5]University of California San Francisco, San Francisco, CA, US; [6]Innsbruck Medical University, Innsbruck, Austria; [7]University of Gothenburg, Gothenburg, Sweden

Background: HIV enters the nervous system soon after seroconversion. Though effects of chronic HIV infection on volumes of cortical and subcortical brain regions are well characterized, little is known about the extent of volumetric alterations that may occur within the first year of infection. We assessed brain volumes in antiretroviral therapy (ART)-naïve subjects with primary HIV infection (PHI, <1 year after initial infection) and age-matched HIV-uninfected participants (HIV-). We correlated volumes with neuropsychological performance (NP), blood, and cerebrospinal fluid (CSF) biomarkers to examine mechanisms of and clinical associations with regional brain volumes during PHI.

Methods: CSF, blood, NP testing, and structural T1 magnetic resonance imaging scans were acquired from 18 HIV- and 48 PHI male participants. Volumetric measurements were obtained (using Freesurfer 5.1) from the following regions of interest (ROIs): caudate, amygdala, corpus callosum, ventricles, putamen, thalamus, cortical white matter, and total grey matter. Student's t-test assessed volumetric differences in these ROIs between the two groups. Pearson correlations examined relationships during PHI between volumetric measures and biomarkers in CSF [viral load (VL), neopterin, and neurofilament light-chain (NFL)], and blood (VL, CD4+, and CD8+ T cell count), and NP tests [digit-symbol (DSST), grooved pegboard (GPD), finger-tapping (FT), and timed gait (TG)].

Results: PHI (median 106 days after estimated infection) and HIV- participants were similar in age (36.7 and 35.2 years, respectively) and education (16.1 years and 15.42 years). Only the putamen was significantly different (decreased volume) in PHI compared to HIV- ($p=0.05$). Within the PHI group, putamen volume associated directly with decreasing CD4+ count ($p=0.004$, Fig. 1A). Trends for inverse correlations were noted for CSF/plasma albumin ratio ($p=0.07$) and CSF NFL ($p=0.09$). Reductions in putamen volume in PHI participants were associated with worse performance on the DSST ($p=0.05$), FT ($p=0.05$), and TG ($p=0.02$, Fig. 1B) tests.

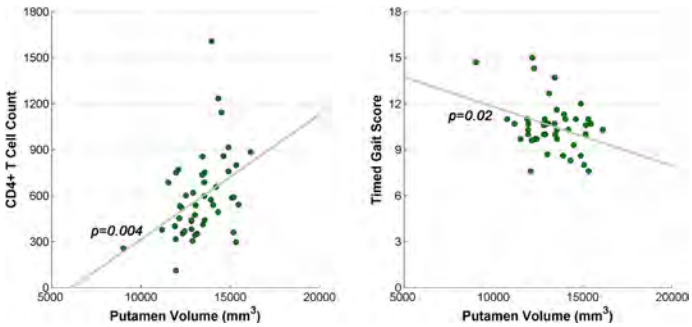

Figure 1. In primary HIV infection, the volume of the putamen (in cubic milimeters) is significantly positively correlated with CD4+ T cell count (A) and inversely associated with decreasing performance on the timed gait neuropsychological task (B).

Conclusions: Our volumetric results suggest that the putamen may be specifically affected in the first year of HIV infection, and the volume of this structure associates with systemic immune measures and neurocognitive performance during this period. Longitudinal analyses are required to assess whether early introduction of ART might stabilize or reverse these structural changes observed in PHI.

61 IRF4 Transcription Factor Associated With Integrated HIV DNA in Brain Macrophages

Benjamin B. Gelman[1]; Joshua G. Lisinicchia[1]; Tetyana P. Buzhdygan[1]; Vipulkumar Patel[1]; Tyler Clement[1]; Samantha A. Trevino[1]; Kristofer R. Jennings[1]; Dennis L. Kolson[2]

[1]University of Texas Medical Branch, Galveston, TX, US; [2]University of Pennsylvania, Philadelphia, PA, US

Background: Integrated HIV DNA (HIV_{int}) can become transcriptionally silenced and latently expressed in certain types of resting lymphocytes. In the brain viral infection occurs predominantly in macrophage type cells in which viral latency is not as thoroughly investigated. To identify the cellular targets of eradication therapy in the CNS we compared macrophage markers in human brain specimens containing high and low concentrations of latent HIV DNA.

Methods: Integrated HIV DNA, total HIV DNA and HIV RNA were measured in frontal neocortex from 40 patients using qPCR or the O'Doherty two-step Alu-Gag assay. Infected patients were separated into those with less than or greater than 3% HIV_{int} relative to the number of HIV RNA copies. Macrophage-expressed mRNAs were measured using qPCR in these groups and a group of 21 seronegative controls. Differences were evaluated with one-way ANOVA and Tukey tests.

Results: High and low HIV_{int} groups had equivalent HIV RNA copies per gram of brain tissue. The group with high HIV_{int} had significantly greater expression interferon regulatory factor 4 (*IRF4*) ($p < 0.03$). mRNAs corresponding to macrophage and microglial type marker antigens CD163, CD14, CD16, Mac387 and Iba-1 were not significantly different. IRF4 protein expression in specimens with higher HIV DNA was localized histologically in brain M2 macrophages preferentially and often was co-localized with low Zeste 2 and high JMJD3, which are two critical elements of the Polycomb Repressor Complex (PRC).

Conclusions: High macrophage *IRF4* mRNA expression is associated with a higher concentration integrated HIV DNA in the brain. IRF4 is a nuclear transcription factor involved in active macrophage polarization towards M2 phenotypes. It is regulated epigenetically by the PRC. The results suggest that HIV-infected macrophages undergoing active polarization toward M2 phenotypes via IRF4 expression contribute disproportionately to the establishment of the latent pool of integrated HIV DNA in the brain.

62 Longitudinal Assessment of Blood Brain Barrier Disruption in Primary HIV Infection

Elham Rahimy[1]; Fang-yong Li[2]; Alex Russell[4]; Julia Peterson[4]; Lars Hagberg[3]; Henrik Zetterberg[3]; Richard Price[4]; Magnus Gisslén[3]; Serena Spudich[1]

[1]Yale University School of Medicine, New Haven, CT, US; [2]Yale Center for Analytical Sciences, Yale University, New Haven, CT, US; [3]University of Gothenburg, Gothenburg, Sweden; [4]University of California San Francisco, San Francisco, CA, US

Background: Abnormal blood brain barrier (BBB) permeability has been implicated in the neuropathogenesis of chronic HIV infection. As neurocognitive impairment can persist despite effective combination antiretroviral therapy (cART), it is possible that irreversible CNS processes are initiated in early infection. We analyzed the natural history of BBB permeability in primary HIV infection (PHI), as well as the effects of cART initiated during this period.

Methods: Blood and CSF were collected from 108 cART-naive participants with PHI (94% male, median age=36, days post-transmission, dpt=91) at baseline and in follow-up visits. 57 of the 108 subjects initiated cART during follow-up for reasons independent of the study. BBB permeability was evaluated as CSF:Serum albumin ratio (QAlb). Baseline log_{10}QAlb was compared with 39 uninfected age-matched control subjects (82% male, median age=38). The mixed-effects model was used to analyze longitudinal change of log_{10}QAlb post transmission, adjusting for baseline age. Longitudinal association between log_{10}QAlb and the axonal injury marker neurofilament light chain (NFL) was examined with between-subject correlation and within-subject correlation.

Results: At baseline, PHI subjects demonstrated elevated median log_{10}QAlb compared to age-matched uninfected controls (0.721 vs. 0.635, p=0.002). Over a median follow-up of 475 dpt in the PHI cohort (median visits=3.0), log_{10}QAlb demonstrated a nearly flat trajectory (slope=-4.9E-5, p=0.532). 23 PHI participants with baseline QAlb greater than previously reported age-specific upper limits of normal (ULN) demonstrated statistically significant yet modest decreases in log_{10}QAlb over time (slope=-0.0017, p=0.013). Levels of those with baseline below the ULN did not change (slope=-7.9E-5, p=0.004). Log_{10}QAlb did not significantly change over time after cART initiated at a median 225 dpt (slope=1.39E-4, p=0.255; median 398 days of treatment, median 2 visits). Log_{10}QAlb correlated with log_{10}NFL as determined by within-subject (r=0.543, p=0.001) and between-subject (r=0.469, p<0.001) correlations.

Conclusions: BBB permeability remains elevated during the course of early HIV infection and does not demonstrate measurable improvement over a year of follow up after cART initiation. Additionally, QAlb was longitudinally associated with increased expression of the neuronal injury biomarker NFL. HIV-associated neuropathogenesis may be initiated and maintained early in the course of infection, and continue despite effective cART.

63 Declining Prevalence of HIV-Associated Neurocognitive Disorders in More Recent Years

Carmela Pinnetti; Raffaella Libertone; Pietro Balestra; Patrizia Lorenzini; Martina Ricottini; Samanta Menichetti; Maria Maddalena Plazzi; Mauro Zaccarelli; Adriana Ammassari; Andrea Antinori

National Institute for Infectious Diseases, Lazzaro Spallanzani, Rome, Italy

Background: Overall prevalence of neurocognitive impairment (NCI) has been estimated as high even in the cART era. More recently, lower NCI prevalence has been found in MSM, suggesting that it may be previously overestimated. Aim of the study was to evaluate prevalence of HIV-associated neurocognitive disorders (HAND) and predictive factors in more recent years of cART impact.

Methods: Single-centre, retrospective, cross-sectional analysis of neurocognitive profile in HIV-infected cART-treated patients. All patients underwent neuropsychological assessment (NPA) by standardized battery of 14 tests on 5 different domains. People were classified as having HAND according to Frascati's criteria. Chi-square for trend, and multivariable logistic regression were fitted.

Results: 569 consecutive HIV-infected cART-treated individuals from 2009 to 2014, contributing a total of 858 NPA tests, were included (male 82%; median age 48 years; MSMs 51%; HCV+ 15%; CD4 nadir >200 cell/ mm^3 61%; current CD4 >350 cell/mm^3 83%; HIV-RNA <40 c/mL 83%). At the time of NPA, 49% of patients were receiving a NNRTI-based, 32% a PIr-based, and 11% a NRTI-sparing regimen, for a median time of exposure to current regimen of 25 months (IQR 9-46). A cognitive complaint of memory loss, attention deficit or concentration difficulties was observed in 313 (36%) tested patients, whereas 545 (64%) were non-complaining. HAND prevalence was 48% in complaining (ANI=23%; MND=21%; HAD=4%) and 16% in non-complaining patients (ANI=12%; MND=4%; HAD=0). By calendar periods, prevalence of HAND in complaining was 50% in 2009/2010, 45% in 2011/2012 and 48% in 2013-2014 (P at chi square for trend=0.74). In non-complaining was 20%, 22% and 9%, respectively (P at chi square for trend=0.004). Factors associated to HAND by multivariable logistic regression are reported in Table.

Table. Factors predictive of HAND by multivariable logistic regression

	Complaining (n=313)			Non-complaining (n=545)		
Factors	OR	95%CI	P	OR	95%CI	P
Age (per 10 years increase)	1.29	0.87-1.72	0.078			
Nadir CD4 - 0-199 - >=200				1.00 0.57	0.33-1.00	0.051
CD4 at NPA - 0-349 - >=350	1.00 0.43	0.24-0.76	0.004			
Years of infection				1.08	1.04-1.12	<0.001
Education (per yr more)	0.82	0.76-0.88	<0.001	0.84	0.78-0.90	<0.001
HCV-coinfection	1.87	0.94-3.69	0.072			
NNRTI-based PIr-based NRTI-sparing	1.00 1.07 0.30	0.58-1.96 0.11-0.81	0.83 0.018	1.00 0.99 0.42	0.54-1.80 0.17-1.09	0.97 0.075

Multivariable models were adjusted for variables with p<0.1 at univariable analysis. The model for complaining was adjusted also for mode of HIV transmission, CDC stage and the model for non-complaining for age and CD4 at NPA.

Conclusions: In very late cART era, in a prevalent MSM population, HAND prevalence was close to 50% only in patients selected to NPA for a cognitive complaint. In people with no specific cognitive complaints, prevalence of HAND was confirmed as lower than previously detected, estimated as less than 10% in the more recent years. Higher CD4 count at NPA, higher CD4 nadir, a shorter time from HIV diagnosis and higher educational level were associated to a lower risk of NCI. Receiving a NRTI-sparing ART at cognitive assessment seems to be related to a lower risk of impaired cognition.

Harnessing Antibodies for Prevention and Therapeutics

64 Potentiating Protective Antibody Activity: A Systems Serology Approach

Margaret E. Ackerman

Thayer School of Engineering, Dartmouth College, Hanover, NH, US

Antibodies act as a nexus between innate and adaptive immunity: they provide a means to engage a spectrum of innate immune effector cells in order to clear viral particles and infected cells. This functional landscape is remarkably complex, as the humoral response is highly polyclonal, with multiple antibody variants directed to multiple epitopes on multiple viral antigens, and diversity of viral recognition characteristics is further complemented by diversity in ability to recruit the potent anti-viral effector functions of a suite of innate immune effector cells. In vivo, even neutralizing antibodies rely on this ability to act as molecular beacons for innate immunity in order to provide protection, and results from both human and macaque studies have implicated these effector functions in vaccine-mediated protection. We demonstrate a high-throughput, high-content platform for the biophysical and functional interrogation of the innate immune recruiting capacity of polyclonal HIV-specific antibodies capable of parsing this complex humoral milieu into components that can be used to develop computational models of antibody activity and provide insights into mechanisms of vaccination.

65 Impact of Repetitive Protein Boosting on RV305 HIV-1 Vaccine-Induced Antibodies

Georgia D. Tomaras

Duke University Medical Center, Durham, NC, US

Of the six HIV-1 vaccine efficacy trials to date, only one trial, RV144, demonstrated decreased transmission *versus* the placebo group, with an estimated vaccine efficacy of 60% and 31% at 12 and 42 months, respectively. Antibodies that significantly correlated with HIV-1 infection risk included IgG (in particular IgG3) non-broadly neutralizing antibodies (non-bnAbs) to the V1/V2 region of HIV-1 envelope glycoprotein. Although not broadly neutralizing, these antibodies could mediate antibody Fc-mediated antiviral functions, such as antibody dependent cellular cytotoxicity (ADCC).

A unique feature of the RV144 vaccine regimen was the inclusion of a protein boost that was antigenic for both linear strain-specific V2 antibodies, as well as for conformational V1V2-glycan epitopes bound by broad neutralizing antibodies (bnAbs). A subset of RV144 vaccinees were boosted, after a 6-8 year interval, as part of the RV305 vaccine trial. This repetitive boosting with the vaccine immunogen both expanded a pool of antibodies with many of the characteristics of V1V2 bnAbs and, as well, skewed the plasma IgG subclass profile associated with non-bnAbs. New technologies have allowed a deeper interrogation of the B cell repertoire post vaccination and provide insights on the quest to induce broadly neutralizing antibodies and / or further drive non-bnAbs with Fc-mediated antiviral functions.

66 Immunoprophylaxis by Gene Transfer: Shortcut to an HIV Vaccine

Phil Johnson

Children's Hospital of Philadelphia, Philiadlphia, PA, US

The holy grail of HIV vaccine development is an immunogen that elicits antibodies which neutralize field strains of HIV from multiple clades. However, little progress has been made in generating such vaccine candidates, and near-term prospects remain uncertain. In the meantime, we have taken a different approach to HIV immunoprophylaxis that completely bypasses the adaptive immune response. The concept is straightforward. One selects an antibody (or antibody-like molecule) with the desired neutralizing properties, clones the respective gene, and then inserts it into a recombinant adeno-associated virus (rAAV) vector. When injected (intramuscularly) into a host, the vector directs *in vivo* production of the antibody that leads to serum neutralizing activity against HIV. In other words, antibodies are produced by myofibers instead of plasma cells. We adapted this

approach for the SIV model system and engineered sterilizing immunity in monkeys against a virulent SIV challenge virus. Importantly, antibody levels in "immunized" monkeys have been stable for over 6 years. We have now moved this concept into Phase 1 human clinical trials.

67 Broadly Neutralizing Antibodies for HIV-1 Eradication Strategies

Dan H. Barouch

Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, US

We have previously shown that the broadly neutralizing monoclonal antibody PGT121 afforded substantial therapeutic efficacy in viremic, chronically SHIV-SF162P3-infected rhesus monkeys. In a recent study, we have also explored the efficacy of PGT121 in ART-suppressed, SHIV-SF162P3-infected monkeys. In addition, we recently observed that the viral reservoir is established very early following infection and prior to viremia. These data demonstrate new challenges facing HIV-1 eradication strategies and suggest novel approaches to target the viral reservoir.

Current Issues in HIV-Related Malignancies

68 HIV-Associated Malignancies: The Worldwide Epidemic

James J. Goedert

National Cancer Institute, Bethesda, MD, US

Background: Malignancies in people with HIV are a major cause of morbidity and mortality. With improving control of HIV infection, the burden and complexities of malignancies are increasing.

Methods: Recent publications and public data were reviewed, focusing on international patterns and differences between AIDS-defining cancers (ADC) and non-ADC.

Results: In the USA, the incidence and burden (total number of cases) of malignancies fell dramatically from 1993-1998, but this was exclusively ADC, specifically Kaposi sarcoma (KS) and non-Hodgkin lymphoma (NHL). Since 1998, age-adjusted incidence has been stable while burden of non-ADC has increased. From 2012-2015, ADC incidence increased 5-10% outside North America and Europe. Southern and especially east Africa continue to have the highest burden of KS. Cervix cancer has had the highest incidence and burden especially in Africa, but most cases do not have HIV. Aging is increasing the importance of ADC, the most important of which are cancers of the lung, anus and liver. Lung cancer is by far the most common ADC, but incidence fell from 1996-2010, perhaps due to smoking reduction. Anus and liver cancers are increasing, probably due to longer survival with HPV and HCV, respectively. Hodgkin lymphoma is decreasing, probably with better control of HIV. Mortality due to NADC has been increasing in most populations.

Conclusions: Implementation of programs to address malignancies are needed, especially in low and middle-income countries. Global access and use of effective antiretroviral therapy is paramount, but research is needed to integrate and optimize combined antiretroviral and cancer therapies. Reducing the burden of cervix and anus cancers will require global access and use of HPV vaccines, but VIA with simplified HPV screening could be a useful interim approach. Liver cancer burden would be reduced with broader use of HBV vaccine and HCV direct-acting agents. Smoking cessation is needed to reduce the morbidity and mortality from lung cancer and many other diseases.

69 Viral Oncogenesis: Evolving Concepts

Shannon C. Kenney

University of Wisconsin, Madison, WI, US

AIDS-related malignancies are often associated with oncogenic viruses, in particular Epstein-Barr virus (EBV) and Kaposi Sarcoma herpesvirus (KSHV). This lecture will discuss how viruses contribute to AIDS-related cancers (with particular emphasis on EBV), and describe novel virus-targeted therapies.

70 AIDS Lymphoma: Advances and Existing Challenges

Ariela Noy

Memorial Sloan Kettering Cancer Center, New York, NY, US

Despite dramatic advances in anti-retroviral therapy, HIV related lymphoma remains a challenge. Lymphoma is the largest contributor to cancer deaths among HIV infected persons and accounts for about 10% of all deaths. Though the incidence has changed, HIV infected person with good CD4 counts still have a marked increase risk of lymphoma with the exception of primary central nervous system lymphoma Gibson et al. (AIDS 2014) have recently estimated an 11 fold increase overall and 17 fold increase for AIDS defining subtypes. These authors also note an increased risk for lymphomas not previously associated with HIV.

71 HIV Malignancies in Low- and Middle-Income Countries: A Double Burden of Disease

Jackson Orem

Uganda Cancer Institute, Kampala, Uganda

One of the hallmarks of AIDS has been the elevated risk of developing cancers linked to immunosuppression. The introduction of highly active antiretroviral therapy (HAART) has greatly changed the natural history of HIV infection and associated morbidities. In Western countries the cumulative risk of developing and dying from AIDS defining cancers (ADCs) such as Kaposi's sarcoma, non-Hodgkin's lymphoma (NHL) and invasive cervical cancer, has significantly declined. On the other hand, non-AIDS-defining cancers (NADCs), such as hepatocellular carcinoma, anal cancer, lung cancer significantly increased.

Cancers therefore still represent a significant burden of HIV-associated morbidity in the current era of HAART worldwide. Few studies have highlighted clearly the impact of scale up of HAART on cancer burden in resource-limited settings such as in Sub-Saharan Africa. It is prudent to state that the highest burden of HIV and cancers are currently found in these countries. It is ironic that in practice linkage between HIV and cancers at this point in LMIC is based on extrapolation from the developed world experience. This has probably contributed to the challenges being faced in translating this model for intervention in LMIC. The resources available and background cancer risks factors in these two settings are diametrical at best.

By and large, the epidemiology of malignancies in the developing world are driven by infectious agents mainly viruses such Human Herpes virus 8(HHV8), Epstein Barr Virus (EBV), human papilloma virus (HPV) infection and hepatitis B and C (HBV and HCV). The observations from these countries still show that the cancers common in HIV-infected individual are very much reminiscent of the era before wide spread use of HAART; given the magnitude of AIDS-defining cancers such as Kaposi sarcoma, non-Hodgkin lymphoma, and cervical cancer.

There is therefore need to better understand the impact of HAART optimization on cancer burden and picture in LMIC. In doing this there must be tools and means for assessing the potential impact of optimized care in LMIC. This may include implementation of interventions that incorporate strategies for both ADC and NADC. Research aimed at understanding local situation but also answering global questions on HIV and cancers at this point can best be done in LMIC. The critical requirement for this undertaking in LMIC must emphasize infrastructure and human capacity development in these countries.

Session S-3 Symposium **Room 6AB**

4:00 pm – 6:00 pm

Current Imperatives in HIV Prevention and Treatment

72 How Has HIV Prevention Affected the Spread of Other Sexually Transmitted Infections?

Marie Laga

Institute of Tropical Medicine, Antwerp, Belgium

At the start of the HIV epidemic in the early 80's, rates of other STI were high among MSM, SW and even general population in many parts of the world. Because AIDS was deadly without cure at the time, attention to primary prevention resulted in sexual behavior change including more condom use. During the late 80thies and 90thies, STI prevalence rates declined substantially. When ART became available and later, evidence emerged that ART can also prevent HIV transmission, the epidemiology of STI changed again. Among MSM in Western countries for example, rates of classic STI (syphilis, gonorrhea) increased since early 2000, and outbreaks of "old" STI (LGV) or "new" STI (Hepatitis C) were described. The possible role of the different HIV prevention strategies on the patterns of STI in different populations will be analyzed and discussed in this presentation.

73 HIV Risks and Vulnerabilities Among Gay Men and Other Men Who Have Sex With Men Across Sub-Saharan Africa

Stefan Baral

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US

In the context of the generalized HIV epidemics across Sub-Saharan Africa, it is often proposed that key populations with specific HIV acquisition and transmission risk factors are less relevant because HIV transmission is sustained among reproductive age adults with average HIV acquisition and transmission risks. While some countries in Western and Northern Africa have concentrated epidemics, the continental countries in Southern and Eastern Africa all have generalized epidemics, a categorization independent of the burden of disease among key poplations including gay men and other men who have sex men (MSM). However, the past decade has witnessed an improved understanding of both the presence of communities of gay men and other MSM across Sub-Saharan as well as their HIV-related risks and vulnerabilities.

Where there are data among MSM, they suggest a complex mixture of individual level, network level, and structural risks for both the acquisition and transmission of HIV. Together, these risks manifest in high prevalence, and where measured, high HIV incidence among young men who have sex with men. Moreover, where phylogenetic data are available characterizing HIV transmission clusters, they often suggest overlap of the circulating strains among MSM with those among other reproductive age men and women. Moreover, there are complex structural determinants of HIV risks including widespread social stigma manifesting in fear of seeking health care, targeted violence, and further criminalization of same-sex practices and even homosexuality as a sexual orientation. These social constructs often result in a data paradox where we know the least about the HIV-risks and vulnerabilities in the places with the most stigma.

Moving forward necessitates a combined effort of academia, community, government, and implementing partners. Improved epidemiologic inputs to inform better mathematical models characterizing population attributable fraction are crucial given the limited investment into the HIV-related needs of these men. Concurrently, adding HIV prevention and treatment options combined with enhanced implementation to improve coverage of existing and future programs is important in changing the trajectory of these HIV epidemics. Lastly, building the evidence base of the adverse public health consequences associated with widespread stigma and increasingly punitive legal contexts may facilitate successful advocacy for the changing of these laws by local champions.

74 An Expanded Behavioral Paradigm for Treatment and Prevention of HIV-1

Thomas J. Coates

University of California Los Angeles, Los Angeles, CA, US

This presentation will address the social and behavioral priorities for prevention and treatment of HIV-1 infection. The approach presented will be based on the premises that (1) Social and behavioral strategies are necessary and essential, but not sufficient for preventing and treating HIV-1 infection; (2) The major advances in prevention and treatment of other infectious and chronic diseases have come about through policy, legislative, and systemic interventions, rather than those focused only on the individual; and (3) The social and behavioral agenda needs to include all of the behaviors (testing, access to care, maintenance in care, adherence to treatment) in comprehensive intervnetions that also include the organization of many actors and systems essential in facilitating prevention or improving treatment. Social and behavioral strategies for achieving high coverage, acceptability, and effectiveness will be presented.

75 Social Protection, Financial Incentives, and Prevention of HIV

David Wilson

World Bank, Washington, DC, US

Background: Social protection may be defined as public actions to reduce extreme poverty and vulnerability. Cash transfers (CTs) are an important and growing element of social protection and may be conditional (CCTs) which are contingent on specified actions or behaviors or unconditional (UCTs) which are not contigent.

A review of the literature identified over 50 randomized controlled trials (RCTs) evaluating the effects of RCTs on education, health and income, including sexually transmitted infections (STIs) and HIV.

Three World Bank RCTs with biomarker endpoints show that cash transfers reduce STI and HIV infection. In Tanzania, people offered up to $60 each annually to stay STI-free had 25 percent lower STI prevalence (De Walque et al 2012). In Malawi, girls and parents offered up to $15 monthly to stay in school had 60% lower HIV prevalence - whether they stayed in school or not (Ozler et al, 2012). In Lesotho, adolescents offered a lottery ticket to win up to $50 or $100 every four months if they stayed STI and HIV-free had a 25% lower HIV incidence - 33% lower among girls and 31% in the $100 arm (De Walque et al 2012).

Discussion: These studies are promising, but have methodological challenges. Tanzania and Malawi used STI and HIV prevalence, respectively. Two NIH HPTN studies reporting soon will provide decisive evidence. Questions to be answered include: (i) is the evidence robust enough? (2) Are cash transfers scalable and sustainable? (3) How durable are the effects, after cash transfers end? (4) Are there opportunities to combine cash transfers with other proven interventions, such as PrEP among the highest risk populations, including key populations and young women in hotspots in hyper-endemic countries?

Special Session: Ebola Virus Disease: Responding to the Challenge

76 The Médecins Sans Frontières Experience with the Current Ebola Outbreaks

Gilles Van Cutsem

Médecins Sans Frontières, Mowbray, Cape Town, South Africa

In December 2013 a two year old child in the village of Meliandou in the southern Guinean forest was infected with the Ebola virus, most likely acquired from a bat. This single zoonotic transmission event has led to the largest Ebola virus disease outbreak in history, which has killed more than 8,000 and infected more than 22,000 people in Guinea, Liberia and Sierra Leone. More than 800 health care workers have been infected; more than 500 have died. As a consequence, the extremely fragile health systems of West Africa almost came to a standstill, resulting in morbidity and mortality of other diseases adding to that of Ebola. Yet most of the response has been carried by West African health workers and communities, while the international response was slow and uncoordinated.

Since March 2014 Médecins Sans Frontières (MSF), in partnership with Ministries of Health, has admitted more than 7,700 patients, among whom nearly 5000 were confirmed with Ebola. MSF provides care in 8 Ebola Case Management Centres and two transit centres, with approximately 650 beds, and has over 300 international and 3800 national staff on the ground in January 2015. Last year, 28 MSF staff members were infected with Ebola, the vast majority in the community; 14 have died. More than 1,400 tonnes of supplies have been shipped. MSF's strategy to control Ebola is organised into six elements: isolation and supportive medical care for cases, including laboratory capacity to confirm infection; safe burial activities; awareness raising; alert and surveillance in the community; contact tracing; and access to healthcare for non-Ebola patients, including protection of health facilities and health workers. These activities are interdependent and all must be in place to contain the epidemic.

As was demonstrated in previous outbreaks as well as recently in the D.R.C., Mali, Nigeria, Norway, Senegal, Spain, the U.K. and the U.S., Ebola outbreaks can be controlled early on by rapid and vigorous outbreak control measures. Yet, the world was unable to contain this epidemic. This presentation will present challenges and lessons learned by MSF during the first year of the response. Incidence has decreased recently yet many challenges remain unaddressed. MSF has called repeatedly on the international community to provide a strong, flexible, and coordinated response, with limited success. The first lesson we must retain is that thousands have died because of international negligence.

77 Ebola Treatment and Vaccine Development and Implementation: Challenges and Opportunities

H. Clifford Lane

National Institute of Allergy and Infectious Diseases, Bethesda, MD, US

WEDNESDAY, FEBRUARY 25, 2015

Session PL-1 Plenary **4AB Auditorium**

8:30 am – 9:00 am

Preventing Pediatric HIV and Managing HIV-Infected Children: Where Are We Now and Where Are We Going?

78 Preventing Pediatric HIV and Managing HIV-Infected Children: Where Are We Now, and Where Are We Going?

Diana M. Gibb

University College London, London, United Kingdom

By 2015, the MDGs and 'Double Dividend' Initiatives aimed for 'virtual' global elimination of perinatal HIV. 2015 also marks 30 years since ACTG 076 trial showed MTCT reduction with AZT; new paediatric HIV is now rare in rich countries. However, globally, 240,000 children acquired HIV in 2015; >90% live in 22 high-burden countries, 21 in Africa. WHO 2013 guidelines recommended 'Option B' pMTCT (endorsed by recent results from the PROMISE trial) or 'Option B+' (ART for life, in high fertility/high HIV countries; now adopted by 15 countries). With pMTCT expansion, new child infections have fallen by ~50% since 2007. Option B+ is also aiding ART rollout to lower-level clinics but challenges of retention on postnatal ART, partner testing and concerns about bone safety of tenofovir for exposed children need further research. Infant HIV diagnosis remains a major challenge; in 2013, <45% exposed infants had DNAPCR by age 2months. More importantly, as >90% HIV-infected children will be born to undiagnosed mothers or those not on ART and 50% children die by their 2nd birthday, a shift is urgently needed to early clinical recognition, HIV diagnosis, and ART with cotrimoxazole prophylaxis initiated locally, alongside pMTCT/treatment for adults. Early infant ART reduced mortality 4-fold in the CHER trial; over >5 years, even ART for 1 or 2 years was superior to delayed ART. Pragmatically, WHO 2013 guidelines recommend ART for children <5years, extended to <15yrs in some countries; recent data suggest this may improve pubertal development and long-term immunological health. By 2013, 760,000 children worldwide had started ART; however, coverage for those needing ART was only 24% (36% in adults), emphasizing need for integration with MCH services and ART harmonization with adults, where possible. Paediatric solid-based combination ARTs are available, dosed by weight bands backed by African data, and as daily regimens (eg 3TC/ABC+EFV). Children respond very well to ART, with few side-effects and even after perinatal ART exposure. Daily dolutegravir for 1st/2nd-line ART is promising, will be evaluated in the planned ODYSSEY trial and may allow better future harmonisation with adults and across paediatric weight bands. With ART, children are reaching young adulthood; global cohort study collaboration through an IAS initiative is focused on adolescent outcomes and linkage of paediatric/adult cohorts; this is vital to study long-term effects of early childhood HIV/ART.

Directing Chronic Virus Infection Through Viral Regulation of Innate Immune Defenses

79 Directing Chronic Virus Infection Through Viral Regulation of Innate Immune Defenses

Michael Gale

University of Washington, Center for Innate Immunity and Immune Disease, Seattle, WA, US

Innate immune defenses are essential for restricting virus replication and spread, and for programming the adaptive immune response for protection against infection. Our studies have revealed key features of innate immunity, starting with nonself discrimination for identification of virus infection, to innate immune effector genes and responses that serve to restrict viral replication and spread. Studies of hepatitis C virus (HCV), a heptotropic RNA virus, have identified RIG-I-like receptors (RLR) signaling of interferon regulatory factor (IRF)3 activation as a critical event initiating the innate immune response to infection from within the host cell. This process propagates through induction of innate immune effectors genes, including type 1 and 3 interferons and interferon stimulated genes (ISGs). ISG products include antiviral factors that restrict virus replication, and proinflammatory cytokines and chemokines that facilitate innate immune cell activation and lymphocyte response toward the infected liver. HCV disrupts these process through the actions of the

viral NS3/4A protease that cleaves MAVS, a key adaptor protein in the RLR pathway, resulting in loss of IRF3 activation and target gene expression, thus supporting viral persistence. Comparison of innate immune signaling outcomes within cells infected with HCV or HIV defines viral regulation of IRF3, and suppression of ISG products, as shared feature of chronic virus infection. Our studies reveal specific nodes of the innate immune response that are subject to viral and host control, and whose actions impart control over the progression of acute to chronic infection transition. Targeting innate immune actions of the host should be formally considered in therapeutic strategies to interrupt persistence for clearance of chronic virus infection.

Session O-6 Oral Abstracts — Room 615

10:00 am – 12:00 pm

Intracellular and Clinical Pharmacology, Drug Interactions, and Adherence

80 Scientific Overview: The Clinical Pharmacology of HIV Prevention

Marta Boffito

Chelsea and Westminster Hospital, NHS Foundation Trust/Imperial College, London, United Kingdom

The combination of tenofovir and emtricitabine is the only PrEP agent that was studied and showed efficacy in preventing HIV transmission, and its pharmacology in this context has been studied in depth. However, prospective randomized clinical trials have reported varying efficacy due to poor adherence to the drug. Importantly, this could be overcome by the introduction of long-acting injectable PrEP agents which may be administered monthly and ensure optimal and prolonged drug exposure in HIV target tissues. Pharmacological studies in the setting of HIV PrEP are fundamental to inform on different drug pharmacokinetics, pharmacodynamics and pharmacogenetics in view of the absence of easily measurable surrogate markers of efficacy, as they play a central role in interpreting drug concentration–responses and optimal drug exposure achievement. Existing strategies for the prevention of HIV infection and ways in which pharmacology may be a valuable resource for understanding drug pharmacokinetics, determining pharmacodynamic targets, identifying optimal drug combinations/doses, frequency of dosing, and designing clinical trials will be discussed.

81 Intracellular Pharmacokinetics of Sofosbuvir In Vivo

Joseph Rower[1]; Ariel Hodara[1]; Jacob A. Langness[3]; Sarah Tise[1]; Greg Everson[1]; Aimee Truesdale[2]; Fafa Baouchi-Mokrane[2]; Lane Bushman[1]; Peter L. Anderson[1]; Jennifer J. Kiser[1]

[1]University of Colorado Denver, Anschutz Medical Campus, Aurora, CO, US; [2]Denver Health and Hospital Authority, Denver, CO, US; [3]University of Colorado Health, Aurora, CO, US; [4]University of Colorado Denver, Anschutz Medical Campus, Aurora, CO, US

Background: Sofosbuvir (SOF), an inhibitor of the Hepatitis C virus (HCV) NS5B polymerase, is a uridine nucleotide analog pro-drug. In cells, SOF is metabolized by host enzymes to GS-331007 (007) mono- (MP), di- (DP), and the pharmacologically active tri-phosphate (TP). There are limited data on the pharmacology of 007 TP in various cell types. We sought to characterize the pharmacology of SOF in peripheral blood mononuclear cells (PBMC).

Methods: PBMC were collected from HCV-infected individuals receiving SOF-based HCV treatment during routine clinic visits. HCV treatment duration was extracted from medical records and times of prior doses were by patient self-report. 007 MP, DP, and TP concentrations were determined using a validated LC-MS/MS assay linear in the range of 50-50000 fmol/sample, then normalized to a concentration per 10^6 cells (fmol/M). Log transformed data were naïve pooled to calculate 007 MP, DP and TP half-lives ($t_{1/2}$). Effects of clinical covariates on 007 phosphate concentrations were tested using unpaired t-tests for categorical covariates or Pearson correlation for continuous covariates.

Results: PBMC were obtained from 45 individuals (29 genotype 1, 28 male, 5 African-American, 31 cirrhotic, 22 decompensated) receiving SOF plus ribavirin (RBV, n=27), simeprevir (SIM, n=7), or both (n=11) for a median (range) of 29 (19, 162) days of treatment and between 2.3 and 27 hours post-dose. All TP samples were quantifiable, while 2 MP and 16 DP were below the limit of assay detection. Median (range) concentrations were 220 (51.5, 846), 70.2 (25.8, 275), and 859 (54.5, 6756) fmol/M for PBMC 007 MP, DP, and TP, respectively. Estimates of $t_{1/2}$ were 13.8 (MP) and 26.0 (TP) hours. MP (203 vs. 375 fmol/M; p=0.03) and TP (970 vs. 2280 fmol/M; p=0.01) were significantly higher in subjects taking SIM. 007 phosphate concentrations did not differ by race, sex, presence of cirrhosis or decompensation and were not significantly correlated with age, weight or creatinine clearance.

Conclusions: 007 phosphates are formed within PBMC, with the TP moiety representing the major anabolite. Higher MP than DP concentrations suggest that DP production may be a rate limiting step. 007 TP was predicted to have a long intracellular half-life in PBMC. SIM co-administration was associated with higher 007 MP and TP, possibly due P-glycoprotein inhibition by SIM. Additional well-controlled pharmacokinetic studies of intracellular SOF are needed, including an assessment of cell-specific pharmacology.

82 Drug-Drug Interactions Between Anti-HCV Regimen Ledipasvir/Sofosbuvir and Antiretrovirals

Polina German; Kimberly Garrison; Phillip S. Pang; Luisa M. Stamm; Adrian S. Ray; Gong Shen; Marc Buacharern; Anita Mathias

Gilead Sciences, Inc., Foster City, CA, US

Background: Use of some anti-HCV agents with antiretrovirals (ARVs) in coinfected patients may be complicated by drug-drug interactions (DDIs). A fixed-dose combination tablet composed of the NS5A inhibitor ledipasvir (LDV) 90 mg and NS5B inhibitor sofosbuvir (SOF) 400 mg is indicated for the treatment of chronic hepatitis C (CHC) genotype 1 infection in adults. We conducted a Phase 1 study to evaluate the potential DDI between LDV/SOF and protease-inhibitor (PI)-containing ARV regimens: ritonavir [RTV, r] boosted atazanavir (ATV/r) or darunavir (DRV/r) plus emtricitabine/tenofovir DF (FTC/TDF; TVD).

Methods: This was a multiple-dose, randomized, cross-over study in healthy volunteers. In Part A (simultaneous dosing), subjects received LDV/SOF, ARVs (Cohort [CH] 1: ATV/r (300 mg/100 mg)+TVD (200 mg/300 mg); CH 2: DRV/r (800 mg/100 mg)+TVD), and LDV/SOF+ARVs each for 10 days. In Part B (CH 3 and CH4), an evaluation of staggered (12 hour) dosing of LDV/SOF and ARVs was conducted.

LDV, SOF, GS-331007 (predominant circulating metabolite of SOF), and ARV plasma concentrations were analyzed and PK parameters were calculated. 90% CIs for the geometric least squares means ratios (%; combination vs. alone) for analytes' AUC_{tau}, C_{max} and C_{tau} were estimated by a linear mixed effect model and compared to lack of PK alteration boundaries of 70-143%. Safety assessments were conducted during the study.

Results: Ninety-five of 96 subjects (N=24/CH) completed the study; one CH 2 subject withdrew consent. Most adverse events (AEs) were Grade 1 or 2. Most commonly reported AEs were ocular icterus with ATV (22%, N=21; CH 1 and 3), headache (19%, N=18; all CH), and nausea (18%, N=17; all CH). One SAE of abdominal pain (Grade 3) was concluded related to ATV/r+TVD by the investigator.

Modest increases in LDV and GS-331007 with ATV/r+TVD and a small reduction in SOF with DRV/r+TVD were observed. Increases in ATV and RTV were also observed, and TFV exposures were elevated with both ARV regimens, following either simultaneous or staggered administration of LDV/SOF.

Pharmacokinetic Results

Change in PK Parameter	Simultaneous				12-Hour Stagger			
	Effect of LDV/SOF on ARVs							
	ATV/RTV+TVD+ LDV/SOF vs. ATV/RTV+TVD							
	ATV	RTV	FTC	TFV	ATV	RTV	FTC	TFV
AUC_{tau}	↔	↔	↔	↔	↑43%	↔	↔	↔
C_{max}	↔	↔	↔	↑47%	↔	↔	↔	↑46%
C_{tau}	↑63%	↑45%	↔	↑47%	↑108%	↑70%	↔	↑38%
	DRV/RTV+TVD + LDV/SOF vs. DRV/RTV +TVD							
	DRV	RTV	FTC	TFV	DRV	RTV	FTC	TFV
AUC_{tau}	↔	↔	↔	↑50%	↔	↔	↔	↑38%
C_{max}	↔	↔	↔	↑64%	↔	↔	↔	↑46%
C_{tau}	↔	↑48%	↔	↑59%	↔	↔	↔	↑52%
	Effect of ARVs on LDV/SOF					
	ATV/RTV+TVD+LDV/SOF vs. LDV/SOF					
	LDV	SOF	GS-331007	LDV	SOF	GS-331007
AUC_{tau}	↑96%	↔	↔	↑134%	↔	↑50%
C_{max}	↑68%	↔	↔	↑75%	↔	↔
C_{tau}	↑118%	NA	↑42%	↑164%	NA	↔
	DRV/RTV+TVD+ LDV/SOF vs. LDV/SOF					
	LDV	SOF	GS-331007	LDV	SOF	GS-331007
AUC_{tau}	↔	↓27%	↔	↔	↓37%	↔
C_{max}	↔	↓37%	↔	↔	↓31%	↔
C_{tau}	↔	NA	↔	↔	NA	↔

Note: 90% CI of the GLSM ratio were within (↔), extended above (↑), or extended below (↓) the predetermined lack of PK alteration boundaries of 70% to 143%; NA: not estimated

Conclusions: Study treatments were generally well tolerated. LDV/SOF increases TFV exposure within RTV-boosted ATV- or DRV-based regimens. The safety of higher TFV concentrations in this setting has not been established. Consider alternative HCV or ARV therapy to avoid increases in TFV. Patients should be monitored for TFV-associated adverse reactions if coadministered.

83 Emtricitabine-Triphosphate in Dried Blood Spots (DBS) as a Marker of Recent Dosing

Jose R. Castillo-Mancilla[1]; Lane R. Bushman[1]; Amie Meditz[2]; Sharon M. Seifert[1]; Jia-Hua Zheng[1]; L Anthony Guida[1]; Edward M. Gardner[3]; David V. Glidden[4]; Robert M. Grant[4]; Peter L. Anderson[1]

[1]University of Colorado-AMC, Aurora, CO, US; [2]Beacon Center for Infectious Diseases, Boulder, CO, US; [3]Denver Health and Hospital Authority, Denver, CO, US; [4]University of California San Francisco, San Francisco, CA, US

Background: Tenofovir diphosphate (TFV-DP) in red blood cells (measured in DBS) is a strong marker of cumulative adherence to tenofovir disoproxil fumarate/emtricitabine (TDF-FTC) and highly predictive of PrEP efficacy. However, because of its long half-life, TFV-DP does not discriminate recent vs. remote dosing. FTC is phosphorylated to FTC-triphosphate (FTC-TP) in red blood cells, which is simultaneously measured with TFV-DP in DBS, but the half-life and clinical utility of FTC-TP have not been elucidated. We aimed to determine the half-life of FTC-TP in DBS and to evaluate its utility as a marker of recent dosing.

Methods: DBS were collected from 13 HIV-negative and 10 HIV-infected adults participating in an intensive pharmacokinetic (PK) study of daily TDF-FTC for 30 days in HIV-negative individuals and 60 days in HIV-infected subjects. DBS were obtained following dosing on days 1, 3, 7, 20, 30 and 60 in all participants and also on days 35 and 45 (off drug) in the HIV-negative group. FTC-TP was extracted from a 3mm punch and quantified using LC-MS/MS with a lower limit of quantification (LLOQ) of 0.1 pmol/punch. Plasma TFV-FTC was quantified using LC-MS/MS with a LLOQ of 10 ng/ml. The FTC-TP half-life was determined using one-compartment first-order PK. To assess the effectiveness of FTC-TP as a marker of recent dosing, the concordance of FTC-TP in DBS with TFV-FTC in plasma was determined by comparing paired plasma/DBS samples collected at various study visits from participants receiving daily TDF-FTC in the iPrEx Open Label Extension (iPrEx OLE). Data are presented as median (range).

Results: Following dosing, FTC-TP reached Cmax at 4 (2-8) hours and exhibited a half-life of 31 (22-52) hours, with no difference according to HIV status (p=0.43). The FTC-TP average concentration at steady state was 0.25 (0.16-0.37) pmol/punch. A total of 482/515 (94%) paired plasma/DBS samples from iPrEX OLE were concordant for detection/non-detection of TFV/FTC in plasma vs. FTC-TP in DBS. When TFV/FTC were BLQ in plasma, FTC-TP was BLQ in DBS 98% of the time. When TFV/FTC were quantifiable in plasma, FTC-TP was quantifiable in DBS 90% of the time.

Conclusions: FTC-TP has a 31 hour half-life in DBS (compared with 17 days for TFV-DP). Excellent concordance (94%) was observed between detection of FTC-TP in DBS with detection of TFV/FTC in plasma, demonstrating that FTC-TP informs recent TFV/FTC dosing, thereby complimenting the long-term cumulative adherence measure provided by TFV-DP.

84 Impact of EFV PK/PG on Neuropsychological Performance in Older HIV+ Patients

Uriel S. Sandkovsky[1]; Anthony T. Podany[1]; Courtney Fletcher[1]; Andrew Owen[2]; Angela Felton-Coleman[1]; Kevin Robertson[3]; Susan Swindells[1]

[1]University of Nebraska Medical Center, Omaha, NE, US; [2]University of Liverpool, Liverpool, United Kingdom; [3]University of North Carolina, Chapel Hill, NC, US

Background: Despite being one of the most commonly prescribed first line antiretroviral agents, the pharmacokinetics (PK) and pharmacodynamics of efavirenz (EFV) and its 8-hydroxy metabolite (8-OH-EFV), have not been robustlyrobustly evaluated in older HIV-infected patients. Moreover, 8-OH-EFV has been shown to be more neurotoxic in vitro than EFV. We sought to investigate relationships between neuropsychological performance (NP) with EFV and 8-OH-EFV PK in HIV-infected individuals >50 yo.

Methods: Cross sectional study of HIV-infected adults >50 yo, on EFV containing ART > 12 weeks. 12 h and 18 h post-dose plasma EFV and 8-OH-EFV were quantified via LC-MS-MS. *CYP2B6* polymorphisms were investigated. NP battery assessed executive function, motor skills, verbal learning, memory, and speed of processing, CES-D depression scale and sleep quality index questionnaire were completed. Correlations of EFV and 8-OH-EFV plasma concentrations with NP performance, sleep, depression scores and *CYP2B6* polymorphisms were assessed (Spearman's correlation, and univariate logistic regression where appropriate).

Results: 30 participants 24 men, 6 women with mean age 57 yrs (50-68)were enrolled. Mean CD4 was 736/mm^3 (range 145-2062); 26 participants had HIV RNA <20 c/mL and 4 < 100 c/mL. Median 12h and 18h EFV plasma concentrations were 1967 ng/mL (IQR 1476-2394) and 1676 ng/mL (IQR 1120-2062) respectively. Median 12hr and 18hr 8OH-EFV plasma concentrations were 378 ng/mL (IQR 223-589) and 384 ng/mL (IQR 216-621) respectively. EFV plasma concentrations did not correlate significantly with NP performance. Higher 8-OH-EFV plasma concentrations correlated with better learning (p=0.002), language (p=0.002) and total NPZ scores (p=0.005). Neither EFV nor 8OH-EFV plasma concentrations

correlated with sleep disturbance or depression. The *CYP2B6* 516G>T polymorphism was associated with significantly higher concentrations of EFV at 12h and 18 h (p=0.02) but not NP function.

Conclusions: Better neurocognitive functioning was associated with higher 8-OH EFV but not EFV plasma concentrations. No correlation was observed with disturbed sleep or depression and exposure to EFV or the metabolite. These findings point to a need for greater understanding of the metabolic profile of EFV and 8-OH EFV in plasma and the CNS and relationships with antiviral effect and neurotoxicity.

85LB Levonorgestrel Implant + EFV-Based ART: Unintended Pregnancies and Associated PK Data

Kimberly K. Scarsi[1]; Kristin M. Darin[3]; Shadia Nakalema[2]; David Back[4]; Pauline Byakika-Kibwika[2]; Laura Else[4]; Sujan Dilly-Penchala[4]; Susan Cohn[3]; Concepta Merry[5]; Mohammed Lamorde[2]

[1]University of Nebraska Medical Center, Omaha, NE, US; [2]Infectious Diseases Institute, Kampala, Uganda; [3]Northwestern University, Feinberg School of Medicine, Chicago, IL, US; [4]University of Liverpool, Liverpool, United Kingdom; [5]Trinity College Dublin, Dublin, Ireland

Background: The subdermal levonorgestrel (LNG) implant is recommended for long-acting, reversible contraception with high efficacy (expected failure rate <1%). Efavirenz (EFV)-based antiretroviral therapy (ART) may decrease LNG pharmacokinetic (PK) exposure via cytochrome P450 mediated drug-interactions. A priori, we hypothesized that over 1 year of combined use, EFV would reduce LNG exposure, but not below the proposed threshold for contraceptive efficacy (180 pg/mL).

Methods: We present the final, 48-week results of a longitudinal, parallel group, PK evaluation of HIV-infected, Ugandan women desiring an implant for contraception. A standard dose LNG implant was inserted at entry in two groups: (1) subjects not yet eligible for ART (control group; n=17); (2) subjects with undetectable HIV-RNA on tenofovir/emtricitabine/efavirenz (EFV group; n=20). At each visit, subjects were counseled on condom use and a pregnancy test was performed. Blood was collected at 1, 4, 12, 24, 36, and 48 weeks after entry and plasma LNG concentrations were analyzed by a validated LC-MS/MS method, with an assay calibration range of 50-1500 pg/mL. Demographic data were analyzed with a T-test or chi-square, as appropriate. PK data were reported as geometric means (GM) and GM ratio.

Results: All women were Black African with a mean age of 31 years. Subjects in the EFV group were on EFV for a median of 10 (range 5-66) months prior to entry. PK data are presented in the Table and reveal a 45-57% reduction in LNG concentrations beginning at week 1 and persisting through week 48. Unexpectedly, 3 women in the EFV group became pregnant between weeks 36 and 48. No pregnancy occurred in the control group. The LNG concentration prior to pregnancy in each subject was 122, 297, and 303 pg/mL, measured 2, 8, and 2 weeks, respectively, prior to conception. For subject safety, the EFV study arm was halted. At the last study visit, 15 subjects (75%) in the EFV group, but no subjects in the control group, had LNG concentrations below 303 pg/mL (the highest concentration at which a pregnancy was observed; p<0.001).

LNG plasma concentrations over 48 weeks

Week	Control group (n=17)	EFV group (n=20)	EFV:Control GM ratio
1	1070 (783, 1356)	462 (370, 553)	0.43 (0.41, 0.47)
4	667 (541, 792)	359 (280, 437)	0.54 (0.52, 0.55)
12	590 (475, 704)	327 (268, 385)	0.55 (0.55, 0.56)
24	528 (423, 633)	280 (212, 348)	0.53 (0.50, 0.55)
36	618 (520, 716)	279 (149, 409)	0.45 (0.29, 0.57)
48	580 (477, 684)	247* (209, 285)	0.43 (0.42, 0.44)

Data presented as pg/mL and geometric mean (GM) with 90% confidence intervals, unless indicated.

* n=11; excludes 3 pregnant patients and 6 subjects who did not reach the week 48 endpoint due to study arm closure.

Conclusions: Contraceptive failures (15%) were seen among HIV-infected women on EFV-based ART within a year of receiving an LNG implant, and LNG exposure was markedly reduced. In addition, the proposed threshold for LNG efficacy (180 pg/mL) was inadequate in our study population. Alternative contraception should be offered to women on EFV-based ART plus LNG implant, but studies of novel implant dosing strategies should be pursued.

86LB A Phase IV PrEP Study Reveals Limited Ex Vivo Potency of Oral Maraviroc Against HIV-1

Julie Fox[1]; Carolina Herrera[2]; Juan Manuel Tiraboschi[1]; Akil Jackson[3]; Laura Else[4]; Natalia Olejniczak[2]; Saye Khoo[4]; David Back[4]; Robin Shattock[2]; Marta Boffito[3]
On behalf of KCL Infectious Diseases Biobank

[1]Guys and St Thomas' NHS Foundation Trust, London, United Kingdom; [2]Imperial College London, London, United Kingdom; [3]Chelsea and Westminster Hospital, NHS Foundation Trust, London, United Kingdom; [4]University of Liverpool, Liverpool, United Kingdom

Background: Oral pre-exposure prophylaxis (PrEP) may be an effective prevention strategy against HIV-1 transmission. All completed PrEP clinical trials have tested ARV acting post-viral entry in the target cell. We present results of the first PrEP study evaluating the potential of an entry inhibitor, maraviroc, in a phase IV, multi-site, open-label, randomized controlled pharmacokinetic and *ex vivo* pharmacodynamic clinical trial.

Methods: 56 healthy adult female (n=26) and male participants (n=30) were randomized to a control arm (Arm A n=6 who had tissue samples taken at two time points one month apart) or to one of 4 intervention arms (n=12 per arm) where a single oral maraviroc 300 mg dose was taken at two time points prior to sampling, one month apart (Arm B: first sampling 2 h post first dose and second sampling 24 h post second dose; Arm C: 4 h and 36 h; Arm D: 6 h and 48 h; Arm E: 12 h and 72 h). Sampling to determine maraviroc concentration included blood, oral fluid and rectal fluid for all. In addition, men provided a urethral swab and a rectal biopsy and women provided a cervico-vaginal aspirate and a vaginal biopsy. Anti-viral activity was assessed by ex vivo challenge with R5-tropic HIV-1_{BaL} of explants cut from mucosal tissue biopsies and measurement of p24 antigen levels in supernatants during 15 days of culture.

Results: Viral replication capacity of HIV-1_{BaL} was significantly reduced (p=0.0005 two-tailed *t*-test) in vaginal biopsies harvested 2h post dosing with p24 levels in culture supernatant at day 15 of culture of 26.74 ± 17.27 pg/ml compared to 200.24 ± 45.89 pg/ml in untreated tissue. No significant reduction of p24 levels were detected at any other time point in vaginal tissue and at no dosing time point in rectal tissue. No Adverse events were reported.

Conclusions: A transient inhibition of ex vivo HIV infection was demonstrated in vaginal tissue 2h after a single oral 300mg maraviroc dose. The lack of inhibition in rectal tissue, despite the ability of Maraviroc to penetrate into the rectum, reveals significant mucosal differences affecting the activity of maraviroc in vaginal and rectal transmission sites. Multi-dosing of maraviroc in humans should be investigated for HIV prevention.

Session O-7 Oral Abstracts — Room 613

10:00 am – 12:15 pm

KS and Cervical/Anal Dysplasia: Tale of 2 Tumors and TB and Other OIs

87 Pomalidomide for Kaposi Sarcoma in People With and Without HIV: A Phase I/II Study

Mark N. Polizzotto[1]; Thomas S. Uldrick[1]; Kathleen M. Wyvill[1]; Karen Aleman[1]; Margaret Bevans[2]; Cody Peer[1]; Douglas Figg[1]; Seth Steinberg[1]; Jerome B. Zeldis[5]; Robert Yarchoan[1]

[1]National Cancer Institute (NCI), Bethesda, MD, US; [2]National Institutes of Health (NIH), Bethesda, MD, US; [3]National Cancer Institute (NCI), Bethesda, MD, US; [4]National Cancer Institute (NCI), Bethesda, MD, US; [5]Celgene Corporation, Summit, NJ, US

Background: Kaposi sarcoma (KS) is a multicentric tumor caused by human herpesvirus 8 and remarkable for its responsiveness to patient immune status. Unmet clinical needs include agents that are oral, anthracycline-sparing, and deliverable in resource limited settings. We evaluated pomalidomide, an oral immunomodulatory agent, in symptomatic KS.

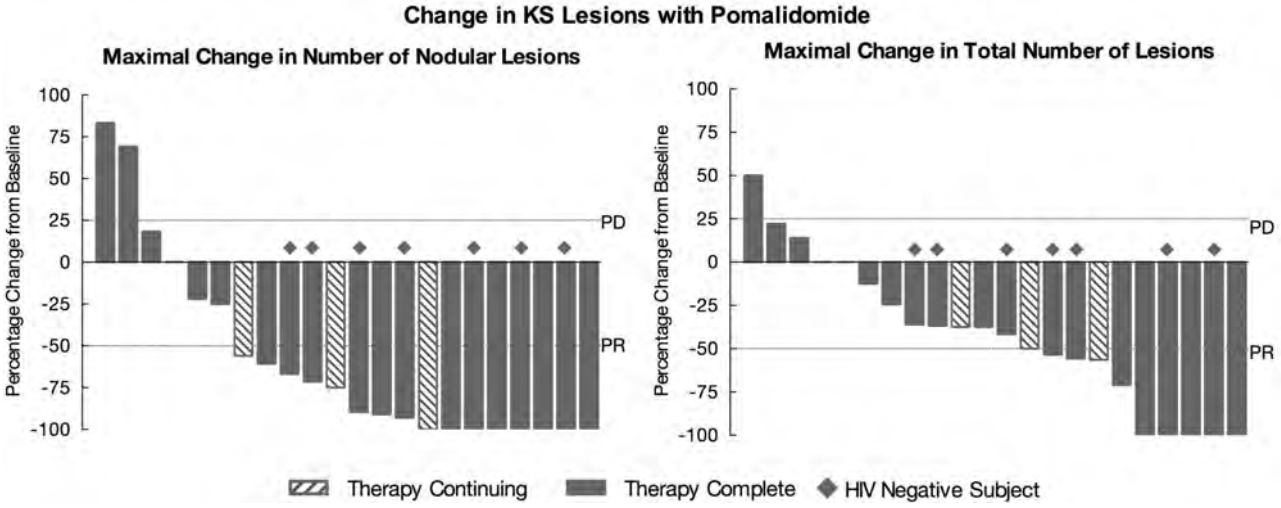
Methods: We performed a prospective phase I/II study to assess the tolerability and pharmacokinetics (PK) of pomalidomide and its anti-tumor activity at the tolerable dose. Primary dose level was 5mg 21 days per 28 day cycle, with a de-escalated level of 3mg if this was not tolerable, and aspirin 81 mg daily as thromboprophylaxis. HIV-infected patients (pts) were eligible if they had controlled viremia and either persistent KS despite 3 months antiretroviral therapy (ART) or progressive KS despite 2 months ART. Evaluations included PK day 1 and 15 cycle 1; KS response by ACTG criteria each cycle; and health related quality of life (HRQL) by FAHI end cycle 3 and end therapy. Study registration NCT1495598.

Results: Primary enrollment completed with 22 pts. All were men; 15 (68%) HIV-infected; med age 50 years (range 32-74); advanced disease (T1) in 16 (72%); prior systemic therapy other than ART in 18 (82%). In HIV-infected, med CD4 429 (135-874); time on ART 48 months (7-227); all HIV VL <50 copies/mL.

No dose limiting toxicities occurred at 5mg and this dose was taken to phase II; all pts were treated at 5mg. Of 148 cycles, grade 3/4 adverse events at least possibly attributable to therapy were: neutropenia (23 cycles [c], 10 pts); CD4 lymphopenia (2 c, 1 pt); and peripheral edema (1 c, 1 pt). Other cytopenias, constipation, rash, and fatigue were common but mild.

15 pts had objective responses (preliminary overall rate 68%, 95% CI 45.1-86.1%): 4 complete (18%) 11 partial (PR, 50%); 4 stable disease (SD, 18%) and 3 progression (13%). 1 pt with SD and 2 with PR continue to improve on therapy. Median time to response 4 weeks (4-36). HRQL showed improved satisfaction with appearance at end therapy (p=0.01), and no impairment during therapy.

PK showed $T_{½}$ 7.1±2.5 hrs, C_{MAX} 61.2±29.3 ng/mL, AUC_{LAST} 624.4±448.4, consistent with prior estimates, no accumulation and no difference by HIV status or ART type.



Waterfall plots show maximal change in the number of nodular lesions (left) and total lesions (right) during therapy for each patient.

Conclusions: Pomalidomide is well tolerated and active in KS regardless of HIV status. Responses were rapid, linked to improved self reported outcomes, and occurred even in advanced and heavily pre-treated KS. Further development could address important unmet needs.

88 Prognostic Model for Patients With Kaposi Sarcoma Treated With ART Alone in Africa

Miriam O. Laker-Oketta[1]; David V. Glidden[2]; Victoria Walusansa[1]; Jackson Orem[1]; A. Rain Mocello[2]; Toby Maurer[2]; Peter W. Hunt[2]; Andrew D. Kambugu[1]; Edward Mbidde[1]; **Jeffrey Martin**[2]

[1]Makerere University College of Health Sciences, Kampala, Uganda; [2]University of California San Francisco, San Francisco, CA, US; [3]Makerere University College of Health Sciences, Kampala, Uganda; [4]University of California San Francisco (UCSF), San Francisco, CA, US; [5]University of California San Francisco (UCSF), San Francisco, CA, US

Background: While patients with functionally disabling Kaposi's sarcoma (KS) require chemotherapy for rapid reduction in tumor burden, the management of KS which lacks functionally disabling complications is less certain. This is particularly true in sub-Saharan Africa, where the relative high cost of chemotherapy makes decisions about its use difficult and the use of antiretroviral therapy (ART) alone common as initial KS treatment. However, because a substantial fraction of patients with KS in Africa who are treated with ART alone fare poorly, it would be useful to be able to predict which patients with KS will do well on ART alone versus those who might benefit from additional interventions.

Methods: We studied HIV-infected adults in Uganda with KS with no functionally disabling complications who were initially treated with ART alone as part of the AntiRetrovirals for KS (ARKS) trial. We evaluated the predictive value of 57 variables regarding clinical history, physical exam, laboratory characterization, and radiographic findings, each

measured prior to ART. The outcome was death or KS progression necessitating chemotherapy. The Least Absolute Shrinkage and Selection Operator (LASSO) was used to identify variables with the highest predictive accuracy upon cross-validation.

Results: Among 224 subjects, 44% were women, and median values prior to ART initiation were: 34 years old, 119 CD4+ T cells/mm^3, and 5.3 $\log_{10}$ copies/ml of plasma HIV RNA. The final prediction model had 3 variables: number of anatomic sites with KS, hemoglobin, and Karnofsky performance score. The model showed adequate discrimination: area under the ROC curve = 0.84 (95% CI: 0.78-0.90), and at an optimal cutpoint, the sensitivity for predicting poor outcome was 88% and specificity 74%. Calibration was also good (Figure). At lower probabilities of observed outcome, the model tended to overestimate the probability of poor outcome, while at higher ranges of observed outcome, it slightly underestimated outcomes.

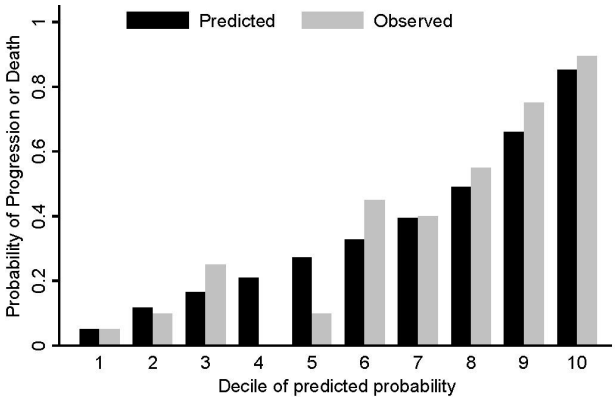


Figure. Calibration of risk prediction model. For each successive decile of predicted probability of progression/death, the mean predicted and observed probabilities for the patients in the decile group are shown.

Conclusions: A prognostic model, consisting of inexpensive measurements, can help to predict which patients in Africa with KS — who present with no functionally disabling complications — will fare poorly when treated with ART alone. The presence of number of KS-containing anatomic sites and hemoglobin in the model suggests the importance of quantitative KS burden in prognosis. The model may help clinicians better advise patients about prognosis and, importantly, inform chemotherapy decisions.

89 One-Year Follow-up of HIV+ Women Screened With VIA, Cytology and HPV in South Africa

Cynthia Firnhaber[1]; Bridgette Goeieman[1]; Lu Mao[2]; Mark Faesen[3]; Simon Levin[3]; Sophie Williams[3]; Avril Swarts[1]; Pam Michelow[1]; Tanvier Omar[1]; Jennifer Smith[2]
[1]University of Witswatersrand, Johannesburg, South Africa; [2]University of North Carolina, Raleigh, NC, US; [3]Right to Care, Johannesburg, South Africa

Background: Cervical cancer is the most common cause of cancer deaths in women in Sub-Saharan Africa. This is due to the burden of the HIV epidemic as well as poor access to screening. Visual inspection with acetic acid (VIA) has been proposed as a screening method for the region, however, there are limited follow-up data for HIV-infected women who have been screened using VIA. This information is needed to inform screening guidelines. We present one year follow up data on a prospective cervical cancer screening study performed in Johannesburg, South Africa.

Methods: HIV-infected women from were rescreened one year later with standard Pap smear and/or colposcopy, VIA and digene HC HPV test, if they had negative or low grade cervical intraepithelial neoplasia (CIN) results at the baseline visit. Associations of progression to higher cervical dyplasia on histology with baseline age, CD4 count, VIA and human papillomavirus (HPV) status were analysed using logistic regression.

Results: A total of 677 of the 1202 women enrolled at baseline were eligible for follow-up and returned at one year. 629 women qualified for colposcopic biopsy and were included in analyses. Median age of the women was 37 years (IQR 32,43). At follow-up, median CD4 count was 387 cells/mm^3 (IQR 250,571) and 93% of the participants were on antiretroviral therapy. Women with CIN 1 and HPV positive results were likely to progress to CIN-2+ [OR 3.63 (1.45-9.1) versus HPV negative]. Women with positive VIA were likely [illegible]e. At one year, 60% (127/211) of the women with either negative [illegible]omen with negative baseline VIA, 18 (4%) progressed to CIN 2+ [illegible]seline were likely to progress at one year [OR 3.09 (1.67-5.72) and

Table. Progression rates, Stratified by Baseline Results.

			Follow-up histology				
Baseline cytology and /or histology	Baseline test results		Negative (N=148)	CIN1 (N=438)	CIN2+ (N=43)	Overall (N=629)	Odds Ratio (CI 95%)
Negative	Overall		84	124	3	211	
	VIA	Negative	83	106	3	192	REF
		Positive	1	18	0	19	13.35 (1.73-102.8)
	HPV	Negative	62	89	1	152	REF
		Positive	22	35	2	59	1.0 (0.52-1.92)
CIN1	Overall		64	314	40	418	
	VIA	Negative	44	186	15	245	REF
		Positive	20	128	25	173	1.85 (0.92-3.72)
	HPV	Negative	32	142	6	180	REF
		Positive	31	172	34	237	3.63 (1.45-9.1)

CIN: cervical intraepithelial neoplasia; HPV: human papillomavirus; VIA: Visual inspection with acetic acid

Conclusions: At one year follow-up, HIV-infected women who were VIA positive at baseline were more likely to progress from negative to CIN 1+ and from CIN 1 to CIN 2+. Of women with negative baseline VIA, 4% progressed to CIN 2+ in a year. HIV-infected women with a positive VIA or HPV should be screened at one year for possible progression.

90 High Rate of HSIL on HRA in HIV+ Women Not Meeting Criteria for Anal Cancer Screening

Michael M. Gaisa; **Fanny Ita-Nagy**; Gabriela Rodriguez Caprio; Michael Mullen; Judith Aberg; Michelle Cespedes
Icahn School of Medicine at Mount Sinai, New York, NY, US

Background: HIV-infected patients have a higher burden of HPV associated high-grade squamous intraepithelial lesions (HSIL) and anal cancer. Guidelines for anal cancer screening in HIV-infected women in New York State include a history of abnormal cervical and/or vulvar histology or history of anogenital warts. The HIV Medical Association of IDSA (HIVMA) screening guidelines include these and add "or a history of receptive anal intercourse" to the criteria as another indication. Best practices for this population are poorly defined. Here we report outcomes and associated risk factors for HSIL in HIV-infected women over five years after implementation of a program which offers anal cancer screening by means of anal cytology to all HIV-infected women regardless of previous HPV disease or sexual behavior.

Methods: Data from women who underwent high resolution anoscopy (HRA) following abnormal anal cytology from April 2009 to July 2014 were reviewed. All HRA were performed by a single operator. Routine clinical data included cervical PAP history, demographics, behavioral data, and HRA results. Chi square tests were used for comparisons.

Results: 306 HIV-infected women underwent HRA, median age was 47, mean CD4 was 537 cells/mm^3, 67% had HIV viral loads <50, 72% had a history of abnormal cervical PAP, and 66% reported a history of anal receptive intercourse. HSIL was found in 28% of anal biopsies. 49% of the 55 women who did not meet criteria for anal cancer screening according to NYS guidelines had anal dysplasia on biopsy. 13 of the 55 women (24%) had HSIL requiring treatment, including one subject with minimally invasive carcinoma. Using HIVMA recommendations, an additional 35 patients met criteria for anal cancer screening. Four of the 20 women (20%) who did not meet screening criteria by either guideline had HSIL on biopsy. Neither meeting NYS criteria, HIVMA criteria, nor a history of receptive anal intercourse as the sole criterion were significantly associated with a diagnosis of HSIL (p=0.079, 0.403, and 0.093 respectively). A history of smoking was the only factor associated with HSIL on biopsy (p=0.002).

Prevalence of HSIL on HRA in HIV Infected Women by Screening Guideline Recommendations

	meets guideline criteria for screening	Number meeting criteria per category	Abnormal lesion on anal biopsy	LSIL on anal biopsy	HSIL on anal biopsy
NYS DOH AIDS Institute Guidelines	Y	251	165	104	61
	N	55	19	10	9
HIVMA of IDSA Primary Care Guidelines	Y	286	184	114	70
	N	20	8	4	4

Conclusions: Anal HSIL was commonly found in HIV-infected women in this cohort. A high rate of dysplasia on biopsy was found even among women who did not meet criteria for routine screening. These results support that all HIV infected women may benefit from anal cancer screening regardless of their cervical / genital HPV history or sex practices.

91 Xpert MTB/RIF Ultra: A New Near-Patient TB Test With Sensitivity Equal to Culture

David Alland[1]; Mazhgan Rowneki[1]; Laura Smith[1]; Jamie Ryan[2]; Mitchell Chancellor[2]; Ann Marie Simmons[2]; David Persing[2]; Robert Kwiatkowski[2]; Martin Jones[2]; Soumitesh Chakravorty[1]
[1]*Rutgers New Jersey Medical School, Newark, NJ, US;* [2]*Cepheid, Sunnyvale, CA, US*

Background: The Xpert MTB/RIF (Xpert) assay, the first near-patient test for tuberculosis (TB), detects *Mycobacterium tuberculosis* (*Mtb*) with a limit of detection (LOD) of 133 CFU/ml sputum, and detects mutations in the *Mtb rpoB* gene which cause Rifampicin resistance (RIF-R). However, despite high sensitivity overall, Xpert sensitivity is only 60 – 80% in smear-negative TB. Also, small numbers of false RIF-R have been reported recently, usually due to abnormal real-time PCR curves or miss-identification of RIF-susceptible (RIF-S) synonymous *rpoB* mutants as RIF-R. A new molecular TB test with an LOD equivalent to the 10 – 100 CFU/ml LOD of liquid culture and improved RIF-R detection is needed.

Methods: For the Xpert MTB/RIF Ultra (Ultra) assay, we developed a new sample processing cartridge that doubled the amount of purified DNA delivered to the PCR reaction. Four newly designed probes that detected mutations in *rpoB* gene replaced the five Xpert real-time probes. Real-time *Mtb* detecting probes targeting IS6110 and IS1081 were added. Cartridge fluidics and PCR cycling were optimized. Assay LODs were tested by spiking *Mtb* H37Rv and BCG cells into sputum samples, treating with Sample Reagent, splitting samples, and testing with Xpert and Ultra. RIF-R detection was tested with a panel of 30 different RIF-R *Mtb rpoB* mutants. LOD was defined as the lowest CFU that could be detected in at least 19/20 (95%) tests.

Results: Ultra was significantly more sensitive than Xpert. In sputum samples spiked with *Mtb* H37Rv, Ultra had an LOD of 5 CFU/ml compared to an LOD of 50 CFU/ml for Xpert (p=0.001). In sputum samples spiked with BCG, Ultra had an LOD of 25 CFU/ml compared to an LOD of 165 CFU/ml for Xpert (p=0.01). Ultra detected 30 different RIF-R *Mtb rpoB* mutants as RIF-R (sensitivity 100%). None of the 25 RIF-S *rpoB* wild type samples and none of the 3 RIF-S synonymous *rpoB* Q513Q (1) and F514F (2) mutant samples were detected as RIF-R (specificity 100%). Ease of use was identical for Xpert and Ultra.

Conclusions: The new Ultra assay is much more sensitive than Xpert, and is likely to be as sensitive as liquid TB culture. Ultra detects RIF-R as efficiently as Xpert; but the specificity of Ultra RIF-R is likely to be higher due to improvements in assay design. The Ultra assay should significantly increase TB detection in smear-negative patients and provide more reliable RIF-R detection.

92 Majority of XDR TB Cases Are Due to Transmission in a High-HIV-Prevalence Setting

N. Sarita Shah[1]; James C. Brust[2]; Barun Mathema[3]; Thuli Mthiyane[4]; Nazir Ismail[5]; Pravi Moodley[6]; Koleka Mlisana[8]; Salim Allana[7]; Jonathan Smith[7]; Neel R. Gandhi[7]

[1]US Centers for Disease Control and Prevention, Atlanta, GA, US; [2]Montefiore Medical Center & Albert Einstein College of Medicine, Bronx, NY, US; [3]Columbia University Mailman School of Public Health, New York, NY, US; [4]University of KwaZulu-Natal, Durban, South Africa; [5]National Institute for Communicable Diseases, National Health Laboratory Service, Johannesburg, South Africa; [6]University of KwaZulu-Natal & National Health Laboratory System, Durban, South Africa; [7]Emory University Rollins School of Public Health, Atlanta, GA, US; [8]University of KwaZulu-Natal & National Health Laboratory Service, Durban, South Africa

Background: Drug-resistant TB threatens gains made in the control of TB and HIV worldwide. In South Africa, there has been a ten-fold increase in the number of MDR and XDR TB cases over the past decade. Factors driving this rapid rise in caseload have not been fully elucidated. We sought to determine the proportion of XDR TB cases resulting from primary transmission versus inadequate treatment of MDR TB (i.e., acquired resistance).

Methods: Cross-sectional study of 400 culture-confirmed patients with XDR TB diagnosed during 2011–2014 from KwaZulu-Natal province, South Africa. Participants were interviewed about demographics, previous TB and HIV history, healthcare utilization, and potential TB exposures. Medical records were reviewed for prior treatment with first- and second-line TB medications and previous hospitalizations. All *M.tuberculosis* isolates underwent IS*6110* RFLP genotyping and targeted sequencing of nine resistance-conferring genes. Isolates from genotypic clusters with more than 20 participants also underwent whole genome sequencing.

Results: To date, 377 patients with XDR TB have been enrolled. The median age was 33 (IQR 29-43) and 57% were female. 78% were HIV-infected, with a median CD4 count of 275 cells/mm^3 (IQR 149 – 433); 90% were on antiretroviral therapy at the time of enrollment and 79% had a viral load <400 copies/ml. Participants were identified from all 11 districts in the province. Only 33% of participants had been previously treated for MDR TB, and an additional 7% had received fluoroquinolones or injectable TB medications for non-TB illnesses. Based on genotypic analysis, 87% of participants had an isolate that belonged to one of 16 clusters; only 13% had isolates that were unique. One large cluster (LAM4/KZN) accounted for 47% of participants, while the remaining cluster sizes ranged from 2–16 participants. Whole genome sequencing confirmed the highly clonal nature of the large LAM4/KZN cluster.

Conclusions: In this high HIV prevalence setting, the majority of XDR TB cases occurred due to transmission of drug-resistant TB strains, rather than prior inadequate treatment of MDR TB. Analysis of epidemiologic and geospatial data also collected in this study will provide valuable insights into identifying potential locations of transmission and opportunities to intervene. TB control efforts must focus on curbing transmission through improved TB case-finding, infection control and enhanced treatment programs.

93 Linkage to HIV/TB Care in South Africa: A Randomized Trial of Health Navigators

Ingrid V. Bassett[2]; Sharon M. Coleman[1]; Janet Giddy[4]; Laura M. Bogart[3]; Christine E. Chaisson[1]; Douglas Ross[5]; Tessa Govender[4]; Kenneth A. Freedberg[2]; Rochelle P. Walensky[2]; Elena Losina[2]

[1]Boston University School of Public Health, Boston, MA, US; [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [3]Boston Children's Hospital, Harvard Medical School, Boston, MA, US; [4]McCord Hospital, Durban, South Africa; [5]St. Mary's Hospital, Mariannhill, South Africa

Background: Despite increases in HIV testing, only a fraction of those newly diagnosed with HIV enter care and initiate ART promptly in South Africa. Our objective was to establish the efficacy of health system navigators for improving linkage to HIV care and TB treatment completion among newly diagnosed HIV-infected outpatients in Durban, South Africa.

Methods: We conducted a randomized controlled trial (Sizanani Trial, NCT01188941) among adult (≥18y) patients enrolled at 4 sites (2 hospital outpatient departments and 2 primary health clinics) prior to HIV diagnosis. HIV-infected participants underwent TB screening with sputum microscopy and culture and were randomized to receive a health system navigator intervention or usual care. Participants in the usual care arm received care according to each clinic's practice. Participants in the navigator arm had a baseline interview using a strengths-based case management approach to assist in identifying barriers to entering care and devising solutions, and then received scheduled phone calls and text messages over 4 months. The primary outcome was 3 months on ART and alive for those ART-eligible at baseline or completion of 6 months of TB treatment. We assessed outcomes via medical records at study sites and the South African death registry 9 months after enrollment.

Results: Of 6,536 subjects screened, 4,903 were eligible and enrolled; 49% were female and mean age was 34 years (SD 13). 1,899 (39%) subjects were HIV-infected, of whom 1,146 (60%) were ART eligible; 369 (19%) were co-infected with TB. In the usual care arm, 197 (21% of HIV-infected and 37% of ART eligible) reached the primary composite study outcome, compared to 212 (22% and 34%, respectively) in the navigator arm (p=0.60). 250/1,899 (13%) HIV-infected subjects died during the study period; there was no difference in death rates between study arms.

Conclusions: Less than 40% of ART-eligible individuals newly diagnosed with HIV in Durban had evidence of taking ART for ≥3 mo or completing TB treatment at the study sites during the nine months after diagnosis. This RCT did not provide evidence that a health navigator-based intervention improves ART initiation or TB treatment completion. Low rates of engagement and retention in care, coupled with the lack of efficacy of the navigator intervention, highlight the urgency of identifying more effective strategies for improving HIV and TB care outcomes.

94 Is It Safe to Stop Cotrimoxazole in Adults on ART: COSTOP, a Noninferiority RCT

Paula Munderi[1]; **Jonathan B. Levin**[1]; Zacchaeus Anywaine[1]; Ronnie Kasirye[1]; Anatoli Kamali[1]; Andrew J. Nunn[2]; Heiner Grosskurth[3]
On behalf of COSTOP Research Team

[1]MRC/UVRI Uganda Research Unit on AIDS, Entebbe, Uganda; [2]University College London, London, United Kingdom; [3]London School of Hygiene and Tropical Medicine, London, United Kingdom

Background: In Uganda, cotrimoxazole (CTX) prophylaxis is recommended as part of a package of comprehensive care. The benefits of continuing CTX in African patients who have regained immune competence through ART are not known particularly in the light of potential disadvantages such as co-toxicity with ART and increased pill burden leading to possible diminished adherence to HIV treatment The objective of COSTOP was to assess the risks and benefits of discontinuing CTX in patients achieving sustained immune restoration.

Methods: From January 2011 HIV-infected patients aged ≥18 years, stable on ART with confirmed CD4 restoration to 250 cells/mm3 and above who consented to join the double-blind trial were randomised 1:1 to one oral tablet of 960 mg of CTX daily or matching placebo. Co-primary outcome measures were (1) time to first CTX-preventable event excluding malaria, (2) time to the occurrence of the first grade 3 or 4 haematological adverse event (AE). Patients attended study clinics monthly during the first 3 months post-randomisation and 3-monthly thereafter for a range of 1 – 3 years. An endpoint review committee adjudicated the efficacy endpoints.

The analysis of the efficacy assesses the non-inferiority of the outcome in the placebo arm compared to the control; non-inferiority required the upper limit of the 90% confidence interval to be less than a 25% increased risk of an endpoint event on the placebo arm. The primary safety analysis assesses the reduction in haematological adverse events in the placebo arm. The study had a minimum of 80% power based on assumptions concerning endpoints in the CTX arm.

Results: 2180 patients were enrolled from two sites in SW Uganda; 74% female, median age 41, CD4 count 518, months on ART 48. 93.3% patients completed at least a year in the study. In the per protocol analysis a total of 124 (54 CTX, 70 placebo) first CTX preventable adjudicated events occurred, hazard ratio adjusted for site and CD4 stratum (aHR) 1.35

(90% CI 1.00,1.81), a difference of 0.9/100 person years. These findings were confirmed in ITT and sensitivity analyses. The incidence of first grade 3 or 4 haematological adverse events was reduced in the placebo arm, aHR 0.70, 95% CI 0.59, 0.82.

Conclusions: Although there was a significant reduction in grade 3 or 4 haematological adverse events in patients allocated to stopping CTX non-inferiority of this strategy with respect to CTX preventable events was not demonstrated.

95LB High-Dose Rifampin, SQ109 and Moxifloxacin for Treating TB: The PanACEA MAMS-TB Trial

Martin J. Boeree[1]; Michael Hoelscher[2]
On behalf of the PanACEA consortium
[1]*Radboudumc, Nijmegen, Netherlands;* [2]*University of Munich, Munich, Germany*

Background: Shorter regimens are urgently needed for the treatment of TB. The PanACEA MAMS-TB trial was conducted to evaluate whether 12-week combinations of high-dose rifampin, SQ109 and moxifloxacin with standard drugs reduced time to culture conversion on liquid media sufficiently to select for a phase III treatment-shortening trial.

Methods: Adult patients with drug-sensitive smear-positive TB were randomly allocated in the ratio 1:1:1:1:2 to be treated for 12 weeks of 1) Q: SQ109 together with standard dose rifampin (R), isoniazid (H) and pyrazinamide (Z), 2) 20RQ: SQ109 and 20 mg/kg R together with ZH, 3) 20RM: moxifloxacin and 20mg/kg R together with ZH, 4) 35R: 35mg/kg R together with ethambutol (E) and HZ, and a control arm for 8 weeks with standard RHZE. All patients then received standard RH to complete a total of 26 weeks of treatment, and were followed for treatment failure and relapse. The trial had a multi-arm multi-stage (MAMS) design with one interim analysis where recruitment to arms could be stopped due to lack of benefit based on pre-specified stopping rules.

Results: 365 patients were randomised from 7 sites in Tanzania and South Africa, of whom 25 (7%) were HIV positive. Recruitment to both SQ109 arms was terminated after the interim analysis; patients on these arms remained on treatment and in follow-up. At the final analysis, covariate-adjusted hazard ratios compared to control over 12 weeks were 0.82 (Q, 95% CI 0.55-1.24), 0.73 (20RQ, 0.48-1.13), 1.42 (20RM, 0.98-2.05), and 1.75 (35R, 1.21-2.55). For comparison to previous TB trials, covariate-adjusted hazard ratios compared to control over 8 weeks were 1.69 (1.02-2.80) for 20RM and 1.99 (1.21-3.29) for 35R. This is the largest reduction in time to culture conversion seen in any previous TB trial to our knowledge. Grade 3 or higher adverse events were experienced by 7(12%) Q, 7(12%) 20RQ, 9 (14%) 20RM, 9(14%) 35R and 12(10%) control patients, of which 1, 5, 7, 4 and 5 were considered at least possibly related to treatment. Hepatic adverse events leading to a change in treatment were experienced by 10 (2.7%) patients.

Conclusions: These data suggest that 35mg/kg rifampin may reduce the time to culture conversion and may be an important component in future treatment-shortening regimens. For 20mg/kg rifampin and moxifloxacin there was a modest reduction; there was no reduction with SQ109. Adaptive designs such as MAMS are feasible for multi-centre TB clinical trials and could speed regimen development.

Session O-8 Oral Abstracts — Room 6E

Factors Affecting HIV Care and Outcome: Global Perspective

96 Special Presentation: PEPFAR 3.0: Controlling the Epidemic and Delivering on the Promise of an AIDS-Free Generation

Ambassador Deborah L. Birx
US Department of State, Washington, DC, US

97 Joint Estimation of HIV Progression and Survival: A Pooled Analysis of 25 Countries

Tara D. Mangal
On behalf of the UNAIDS Working Group on CD4 Progression and Mortality Among HIV Seroconverters including the CASCADE Collaboration in EuroCoord
Imperial College London, London, United Kingdom

Background: National estimates of antiretroviral treatment (ART) need and coverage, based on CD4 cell count thresholds, are generated by most countries using the Spectrum model. This uses model parameters for survival and CD4 progression that are derived from separate analyses. We developed a model which simultaneously estimates CD4 decline and survival in HIV-positive individuals by age, sex, and geographic region. We use the largest pooled dataset to date, collating data from 50 HIV seroconverter cohorts and collaborations in Africa, Europe, North America and Asia.

Methods: We used a hidden Markov model to describe survival and CD4 decline following seroconversion in the absence of ART. The model estimates forward-only transition rates through six transient states characterised by ranges of decreasing CD4 levels, towards two absorbing states, corresponding to ART initiation and death. We stabilised variability in CD4 counts using a log transformation. Natural short-term fluctuations along with measurement errors in CD4 cell counts were accounted for using a normal measurement error model. Covariates were included on the transition rates and survival probabilities were estimated for each subgroup.

Results: The 27,511 eligible individuals had a median follow-up time of 3.55 (IQR 1.71, 6.20) years, were predominantly male (74.1%) and had a median age at seroconversion of 29.1 (IQR 24.4, 35.4) years. Of these individuals, 23,031 had recorded CD4 counts pre-ART, 1943 died, and 14,519 initiated ART. Median (95% CI) survival for males aged 20 years at seroconversion was 11.6 (10.6-12.1), 11.3 (10.5-11.7) and 9.0 (8.7-9.4) years in Africa, Europe/North America and Asia, respectively. The mean time from seroconversion to CD4 counts <500 cells/mm^3 for males in Africa aged 20 years was 3.02 years, conditional on starting above 500 cells/mm^3. Transition rates and all-cause mortality rates progressively increase with increasing age (hazard ratio [HR] 1.02, 95% CI 1.02-1.03 for every five years of age for CD4 stages, HR 1.17, 95% CI 1.17-1.18 for mortality).

Conclusions: CD4 decline and mortality after HIV infection in the absence of ART was similar in African, European and North American cohorts, but significantly faster for all ages in Asian cohorts. Older age is associated with an increased hazard for progression. Joint estimation of these parameters reveals heterogeneities between regions and ages, which should be incorporated into future HIV models to accurately estimate ART need and coverage.

98 Impact of Emergency Department HIV Testing and Linkage to Care: 25 Years' Experience

Gabor Kelen[3]; Eshan U. Patel[2]; Yu-Hsiang Hsieh[3]; Oliver B. Laeyendecker[2]; Judy Shahan[3]; William Clarke[3]; Jordyn L. Manucci[3]; Richard Rothman[3]; **Thomas C. Quinn**[2]
[1]*Johns Hopkins University School of Medicine, Baltimore, MD, US;* [2]*National Institute of Allergy and Infectious Diseases (NIAID), Baltimore, MD, US;* [3]*Johns Hopkins University School of Medicine, Baltimore, MD, US*

Background: The Johns Hopkins Hospital (JHH) Emergency Department (ED) has served as both an observational window on the HIV-epidemic for over 25 years, and as a pioneer in ED-based testing and linkage to care programs. We document the changing nature of the local epidemic in inner city Baltimore and the success of ED-based strategic approaches to curtail the epidemic.

Methods: We analyzed 7 discrete identity-unlinked serosurveys conducted on 18,240 untargeted adult JHH-ED patients between 1987-2013 for demographic trends in HIV prevalence, cross-sectional incidence estimates, viral load and HCV prevalence. JHH ED HIV testing and linkage to care programs were initiated in 2005 and continue to date.

Results: HIV prevalence in 1987 was 5.2%, peaked at >11% from 1992-2003, and then declined to 5.6% in 2013. While seroprevalence was highest for black males, (initial 10%, peak 20%, last 10%), and lowest for white females, the time trend for prevalence was consistent for all groups. Proportion of undiagnosed HIV declined over time from 77% in 1987, 28% in 1992, and 12% by 2013 ($p<0.001$). HIV incidence estimates in 2001 were 2.1% and declined steadily to 0.16% by 2013 ($p<0.001$). Proportion of HIV+ individuals with viral suppression (<400 c/ml) increased steadily from 23% in 2001 to 59% by 2013 ($p<0.001$). Consistent with increasing viral suppression, 80% of 214 HIV+ individuals surveyed in 2013 had antiretroviral drugs detected in their sera, a marked increase from 2007 (27%) ($p<0.001$). The trends in improved outlook were consistent in all demographic subgroups. However, HCV in this population remained at 18-19% from 1988 until 2007 and declined only slightly to 14% by 2013. Dual HIV/HCV infection remained relatively stable (48%-52%) from 2007 to 2013.

Conclusions: Over a 25-year period, JHH ED-based HIV testing evolved from describing the local epidemic to playing a major strategic role in locally controlling the epidemic. This is evidenced by declining undiagnosed HIV infection, increased use of ARVs with increasing viral suppression and a consequential decline in incidence among JHH ED patients. While causation is not directly addressed, the improvements in HIV status in this population coincide with JHH ED-based testing, while the linkage to care program is associated with increased ARV therapy. Noting only a comparative slight decrease in HCV infection in the same population underscores the potential for a causal relationship.

99 Linkage to Care and Viral Suppression Among New HIV Diagnoses, New York City, 2006-13

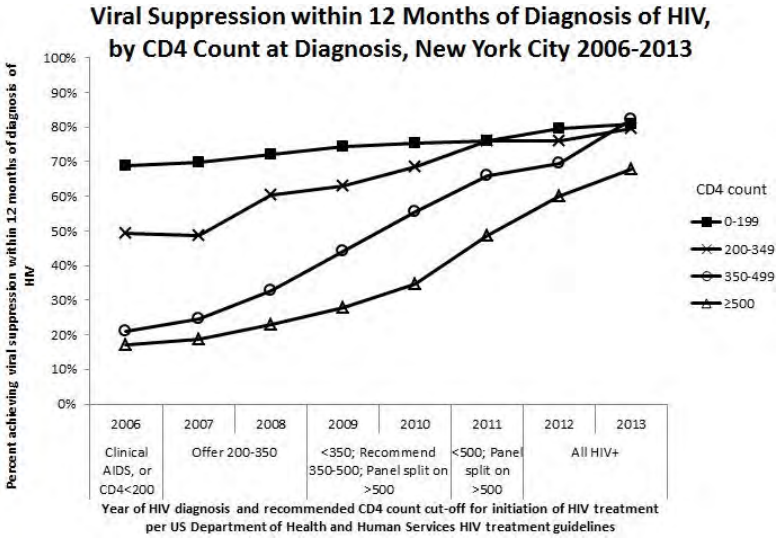
Ellen W. Wiewel; **Lucia V. Torian**; Qiang Xia; Sarah L. Braunstein

New York City Department of Health and Mental Hygiene, Long Island City, NY, US

Background: Since 2007, US Department of Health and Human Services (DHHS) HIV guidelines have advocated timely linkage to medical care (LTC) and progressively earlier initiation of antiretroviral therapy (ART) after diagnosis. A 2010 New York State law required LTC for consenting newly diagnosed persons. Less-immunocompromised and younger adults have historically had lower rates of LTC and viral suppression (VS). Trends in LTC and VS in New York City (NYC) can indicate provider uptake of new guidelines and whether differences in outcomes by immune status and age have been reduced.

Methods: Using NYC HIV surveillance registry data as of 6/30/2014, we calculated timely LTC and VS among residents 18+ years newly diagnosed in 2006-13 who survived >91 days post-diagnosis, overall and by CD4 count and age at diagnosis. Timely LTC was defined as CD4 or viral load (VL) test 8-91 days post-diagnosis. VS was defined as VL ≤400 copies/mL, measured by 6, 9, and 12 months post-diagnosis. CD4 count at diagnosis was imputed from value and timing of first CD4, assuming 50-cell/year decrement, and categorized in intervals of 0-199, 200-349, 350-499, and ≥500 cells. Trends by diagnosis year were assessed by Cochran-Armitage and differences by CD4 and age by Chi-square.

Results: Timely LTC increased overall (68% to 76%, $p<0.0001$) and across all CD4 intervals and all age groups <55; LTC did not change for persons ≥55. VS also increased overall (24% to 54% by 6 months, 32% to 65% by 9, and 36% to 69% by 12, all $p<0.0001$) and for all CD4 intervals and age groups. Percent VS by 12 months nearly quadrupled for persons with CD4 ≥350 (19% to 73%) and more than doubled for persons 18-34 (30% to 66%). Concordant with changes in guidelines, increases in LTC were steepest in 2010-11, and increases in VS escalated in 2007-8 for persons with CD4 200-349, 2008-11 for 350-499, and 2010-12 for CD4 ≥500 (Figure). In 2006, LTC and VS at 12 months differed across CD4 intervals and age groups ($p<0.0001$). However, by 2013, differences were observed only between persons with CD4 <500 and ≥500.



Conclusions: Timely LTC and VS increased over the entire period (2006-13) among persons newly diagnosed and reported with HIV in NYC, overall and in most CD4 and age groups. Some larger year-over-year increases in LTC and in VS by CD4 follow updated recommendations. These favorable trends notwithstanding, as of 2013, NYC was still far from the ideal of timely LTC and VS for all newly diagnosed residents.

100 Care and Viral Suppression Among Women, 18 US Jurisdictions

Ndidi Ike; Angela L. Hernandez; Qian An; Taoying Huang; H. Irene Hall

US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US

Background: Women comprise 25% of persons living with HIV in the United States. The HIV diagnosis rate for black and Hispanic women is 19 and 3.5 times, respectively, the rate for white women. Overall, disparities also exist in care and treatment outcomes by race/ethnicity. We assessed differences in care and viral suppression among women.

Methods: We used data from the National HIV Surveillance System reported from 18 US jurisdictions to determine care and viral suppression among women aged ≥13 years. Linkage to care, defined as ≥1 CD4 or viral load (VL) test within 3 months of diagnosis, was assessed for women diagnosed in 2012. Retention in care (i.e., ≥2 CD4 or VL tests at least 3 months apart in 2011) and viral suppression (i.e., most recent VL ≤200 copies/mL in 2011) were determined for women living with HIV during 2011. Data were statistically adjusted for missing HIV transmission categories.

Results: Among 3,903 women diagnosed with HIV in 2012, 83% were linked to care. Women aged 13-24 years had the lowest percentage of linkage to care compared to those aged ≥55 years (78% vs. 85%). Similar percent distributions by age were observed in all race/ethnicity groups. Among 102,726 women living with HIV in 2011, 52% were retained in care. The percentage in care was higher among older women (≥ 55 years, 57%) compared with younger women (e.g., 13-24, 54%; 25-34, 46%). The percentage retained in care was comparable among blacks (48%) and whites (51%) but higher among Hispanics (59%); the percentage was lowest among American Indians/Alaska Natives (33%). Overall,

44% of women had a suppressed viral load and it was higher among older (≥ 55 years, 53%) compared with younger women (13-24 years, 33%). Viral suppression was highest among Hispanics (49%), followed by Asians (48%), whites (47%), and blacks (42%), and lowest among American Indians/Alaska Native (30%). Retention in care was similar but viral suppression was lower among women who inject drugs (42%) compared with heterosexual women (46%).

Conclusions: Almost half of women living with HIV were not in regular HIV care, and retention in care and viral suppression differed by race/ethnicity and age. Black-white differences in viral suppression among women are smaller than previously observed for men and women combined. Improvements in care and treatment outcomes are needed for all women, with particular focus on younger women.

101 Time Above 1500 Copies/ml: A Viral-Load Measure for Assessing Transmission Risk of HIV-Positive Patients in Care

Lytt I. Gardner[1]; Gary Marks[1]; Charles Rose[1]; Meg Sullivan[2]; Susan Holman[3]; Jeanne Keruly[4]; Anne Zinski[5]; Allan Rodriguez[6]; Thomas Giordano[7]

[1]Centers for Disease Control and Prevention, Atlanta, GA, US; [2]Boston University School of Medicine, Boston, MA, US; [3]Colleges of Medicine and Nursing, SUNY Downstate Medical Center, Brooklyn, NY, US; [4]Johns Hopkins University School of Medicine, Baltimore, MD, US; [5]University of Alabama at Birmingham, Birmingham, AL, US; [6]Miller School of Medicine, University of Miami, Miami, FL, US; [7]Baylor College of Medicine, Houston, TX, US

Background: HIV-positive persons aware of their serostatus account for about 50% of HIV transmissions. As entry and retention in care improves, proportionally more of these transmissions will come from HIV patients in care. We assessed the HIV transmission potential of patients in care by examining the amount of person-time (PT) they spend above a viral load (VL) threshold that increases risk for transmission.

Methods: The analysis included 14,532 HIV patients in six HIV clinics in the U.S. from April 1, 2009 to March 31, 2013. We examined HIV transmission potential by using longitudinal cohort data on VLs and amount of PT spent above a VL threshold (1500 copies/ml) that increases risk for transmission. Eligible patients had to have ≥30 days between their first and last VL test (total observation time). Consecutive VLs and the duration between them were used to generate PT: when two consecutive results were ≤1500 copies, then all PT was below the threshold; when two consecutive results were >1500 copies, then all PT was above the threshold; when one result was above and the other one below the threshold, then PT was estimated based on the magnitude of the difference in the two VLs and the extent to which the larger VL exceeded the 1500 copies/ml threshold. Poisson regression with robust standard errors was used to estimate the rate (percent) of PT above the threshold. A multivariable model of time above the 1500 copies threshold controlled for demographic and clinical predictors.

Results: Overall, the HIV VL exceeded 1500 copies/ml during 23% of patients' observation time (average, 84 days per person, per year); 54% of the patients had one or more VLs above 1500. In the multivariable model, the percentage of PT above the 1500 threshold was significantly higher among: patients aged 16 to 39 (32%) and 40 to 49 (23%) vs. 50+ years (16%) ; black (26%) vs. white (16%) patients; those who injected drugs (26%) vs. those who did not (23%); patients with an initial VL >1500 copies/ml (51%) vs. <1500

Estimate of percentage of person-time with viral load (VL) exceeding 1500 copies/ml, by demographic and clinical subgroups, Retention in Care Study, 2009-2013.

Subgroups	Subgroup N (%)	% of observation time VL exceeded 1500 copies/ml	95% CI	Unadjusted rate ratio	95% CI	Multivariable adjusted rate ratio	95% CI
Overall	14,532	23.08	22.51, 23.66

Viral load > 1500 copies/ml as initial VL in analysis							
Yes	5479 (37.7)	50.81	49.72, 51.93	4.85	4.60, 5.11	4.21	3.96, 4.46
No	9053 (62.3)	10.48	10.00, 10.98	ref.		ref.	

Conclusions: Several subgroups of HIV-positive patients in care spent a quarter or more of their time with VLs above 1500 copies/ml, putting them above the threshold for potentially transmitting HIV to others. Efforts by HIV clinicians and patients to maximize the duration of time with VL below 1500 copies/ml will reduce the risk of HIV transmission.

102 Incidence and Risk Factors for Sexual Assault Among MSM and Young Women in Coastal Kenya

Adrian D. Smith[1]; Sam Rogers[1]; Elizabeth Wahome[2]; Marianne Darwinkel[2]; Susan M. Graham[3]; Eduard J. Sanders[2]

[1]Nuffield Department of Population Health, Oxford, United Kingdom; [2]Centre for Geographic Medicine Research – Coast, Kilifi, Kenya; [3]University of Washington, Seattle, WA, US

Background: Experience of rape presents direct and indirect risks for HIV transmission. Sex workers and men who have sex with men (MSM) in Africa are widely criminalized and may experience discrimination in interactions with public and organised society.

Methods: Data were from cohorts of HIV-negative and HIV-positive adults in Coastal Kenya since 2005. Follow-up included periodic risk behaviour assessment, including occurance of rape in the prior 3 months. Incidence of first rape was estimated for male and female participants separately. We estimated adjusted odds ratios (AOR) of rape for

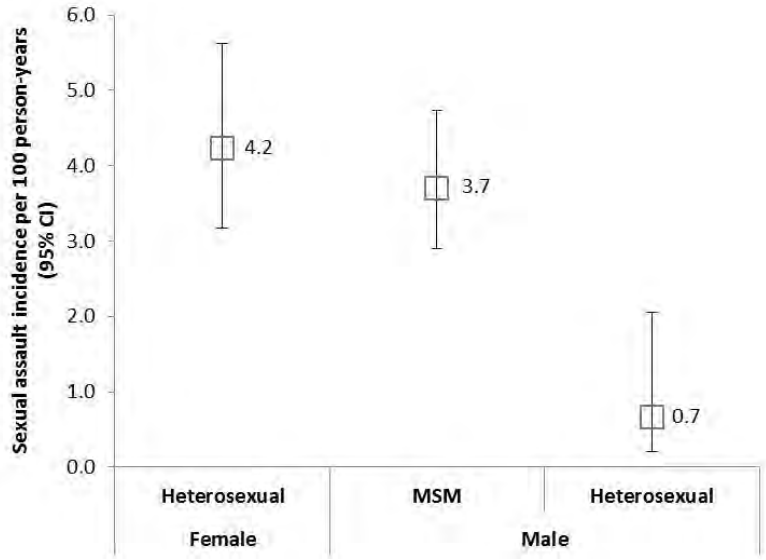
sociodemographic and behavioral covariates reported at each follow up visit using generalized estimating equations with a logit link and HIV incidence rate ratios (IRR) using Poisson regression for MSM who were HIV negative at enrolment.

Results: 1,425 adults were enrolled: 970 men (727 MSM and 243 heterosexual men) and 455 women. 86.1% of MSM, 29.2% of heterosexual men and 80.7% females reported selling sex during follow up.

8.8% MSM, 1.2% heterosexual men and 10.3% women reported being raped at least once during follow-up (rates in figure). Assailants were often family members or neighbours (MSM: 49.5% (64/727); females 55.7% (47/455) whilst 10% were public officials (MSM: 9.5%; females: 9.8%). MSM assailants were more likely to be strangers (26.7% MSM assaults vs. 9.8% female assaults p=0.010).

For men, rape was associated with selling sex in the past 3 months (AOR 3.8 [1.7-7.4] p<0.001), behavioural orientation (exclusive MSM: AOR 4.4 [1.0-18.1], bisexual MSM: 1.7 [0.4-6.9] vs. heterosexual orientation, p=0.012); young age (18-24 yrs: AOR 12.5 [1.1-138.0], 25-34 yrs: AOR 8.2 [0.8-89.3] vs. 35 yrs+ p=0.012) and participation in group sex in the last 3 months (AOR 3.0 [1.7-5.3], p<0.001). For women, rape was associated with selling sex in the past 3 months AOR 2.6 [1.0-6.6] p=0.048 and being HIV negative (AOR 4.8 [1.2-20.0] p=0.024.

Crude HIV incidence was higher among MSM reporting rape in the previous 3 months: IRR 5.7[1.8-18.0] p=0.003, but not when adjusted for behaviors common to both HIV and rape risk: AIRR 1.6 [0.5-5.2] p=0.458.



Incidence of first rape by gender and sexual orientation

Conclusions: Rates of rape among key populations in coastal Kenya are significant and events signal HIV risk for MSM. Multicomponent HIV prevention strategies for these populations should include immediate care pathways for victims of sexual abuse (including post-exposure prophylaxis). The impact of sexual assault upon mental health and prevention self-efficacy should be explored.

103LB Impact of the Ebola Epidemic on HIV Care in Macenta, Forest Guinea, 2014

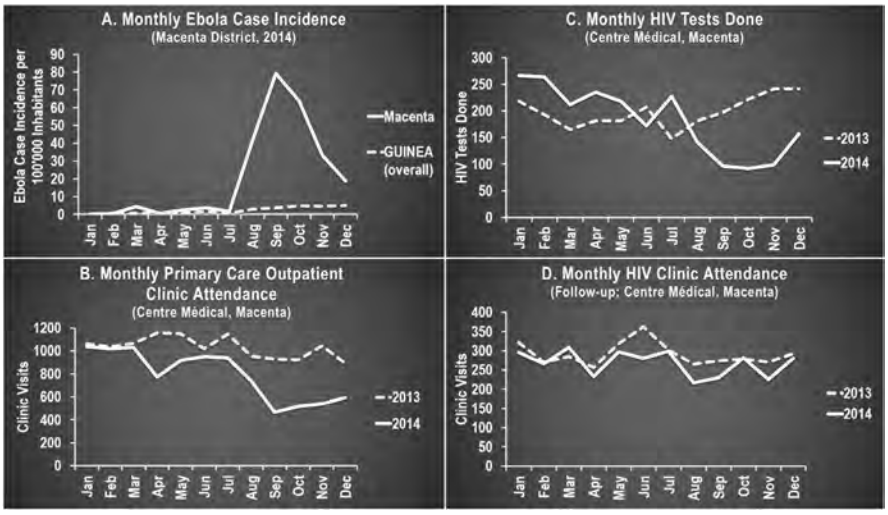
David Leuenberger[1]; Jean Hébélamou[1]; Stefan Strahm[1]; Gilles Wandeler[2]; Nathalie de Rekeneire[3]; François Dabis[3]
On behalf of International Epidemiological Databases to Evaluate AIDS - West Africa

[1]Mission Philafricaine, Conakry, Guinea; [2]Department of Infectious Diseases, University Hospital Bern, Bern, Switzerland; [3]Université Bordeaux, ISPED, Centre Inserm U897-Epidemiologie-Biostatistique, Bordeaux, France

Background: Macenta district (300,000 inhabitants) is one of the worst hit areas by Ebola virus in West Africa: cumulative incidence was 745 cases as of 12/31/2014 (250 cases/100'000, 10 times the country figure), and monthly incidence peaked at 79 cases/100'000 in September (Fig. A). The Centre Médical de Macenta, a public-private partnership between the Guinea Ministry of Health and the non-governmental organization Mission Philafricaine, offers general primary care services and runs the only HIV treatment center in the district. We assessed the impact of the ongoing epidemic on general/HIV care in Macenta.

Methods: We analyzed prospectively collected hospital data and linked them to Ebola surveillance data. Program indicators were compared between 2013 and 2014, with a focus on the epidemic period (August-December): overall use of hospital services, HIV services for new patients and for those already in care.

Results: No change in the availability of hospital services was reported throughout 2014; the catchment population was stable. Among the 60 hospital employees, there was one Ebola-related death (laboratory service) in 2014. Dispensation of antiretroviral drugs (ARV) increased by 26% from 2013 (N=675 patients in care) to 2014 (N= 780, of whom three are known to have died of Ebola). Yet there was a 40% drop in primary care outpatient clinic visits in August-December 2014 (ref. same period of 2013) (Fig. B), a 43% drop in out-of-pocket patient spendings (service fees and drug purchases), a 53% drop in newly diagnosed cases of tuberculosis, a 46% drop in HIV tests done (Fig. C), a 53% drop in patients newly diagnosed with HIV, and a 47% drop in HIV care enrolment. HIV follow-up dropped only by 11%, from 276 clinic visits per month in August-December 2013 to 247 for the same period of 2014. (Fig. D). Of the 185 patients newly enrolled in the first semester of 2014 (baseline median CD4 count 272/mm^3; IQR 106-457) 18.4% were lost to follow-up (LTFU) at six months during the epidemic period (def.: 30-day lateness after next scheduled visit). This LTFU 6-month indicator was 20.1% for the cohort of 204 patients enrolled in the first semester of 2013 (baseline CD4 count 230/mm^3; 84-410).



Ebola cases in Macenta district (A) and impact on primary care outpatient clinic attendance (B), HIV tests done (C) and HIV follow-up clinic attendance (D), all at the Centre Médical, Macenta

Conclusions: The Ebola epidemic resulted in a major drop in attendance of general outpatient services and thus in HIV testing and enrolment of new HIV+ patients, despite a continuous and unaltered service offer. We were however able to sustain HIV care for those already followed in this epidemic context.

103-ALB Favipiravir in Patients with Ebola Virus Disease: Early Results of the JIKI trial in Guinea

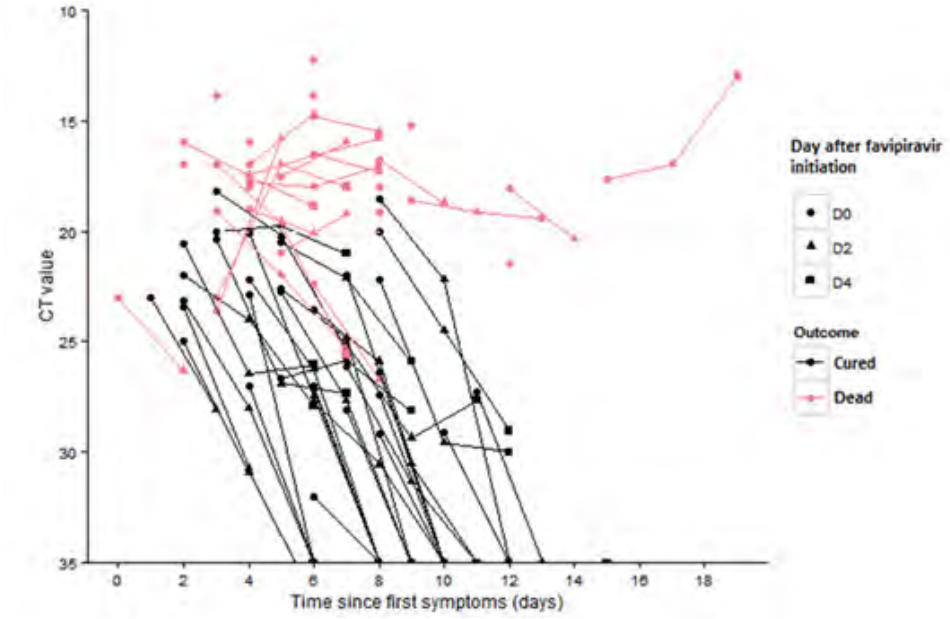
Daouda Sissoko[1], Elin Folkesson[2], M'lebing Abdoul[3], Abdoul Habib Beavogui[4], Stephan Gunther[6], Susan Shepherd[3], Christine Danel[1], France Mentre[5], Xavier Anglaret[1], **Denis Malvy**[1]

[1]Inserm U897, Université de Bordeaux, Bordeaux, France; [2]Médecins Sans Frontières, Bruxelles, Belgium; [3]ALIMA, Montreuil, France; [4]Centre de Formation et de Recherche en Santé Rurale de Maférinyah, Conakry, Guinée; [5]Inserm U738, Université Paris Diderot, Paris, France; [6]Bernhard-Nocht-Institut für Tropenmedizin, Hamburg, Germany

Background: The JIKI trial (Inserm C1463) assesses the benefits of high-dose favipiravir in reducing mortality and decreasing Ebola virus (EBOV) viral load in patients with Ebola virus disease (EVD).

Methods: JIKI is a phase II trial conducted in 2 Ebola treatment units run by MSF and ALIMA in Guinea. Inclusion criteria are: positive EBOV RT-PCR (Altona, crossing cycle threshold [CT] for positivity<40), age >1 year, ability to take oral drugs, and informed consent. Participants are prescribed oral favipiravir (adults: 6000mg Day [D]0 [H0 2400mg, H8 2400mg, H16 1200mg], and then 1200mg bid from D1 to 9). The primary endpoint is mortality. Mortality among participants is compared to mortality during the 3 month period preceding trial initiation in the same centers, as recorded in the MSF/EMLab database. On January 22, the DSMB recommended that the investigators present data on the first 69 adults and adolescents.

Results: from Dec 17, 2014 through January 20, 2015, 80 patients received favipiravir, including 69 adults and adolescents >14years (women 64%, mean age 38 years, median duration of illness 5 days). The baseline CT (BCT) was<20 in 42% and >20 in 58%; the baseline creatinine was >110 µM/L in 60% (BCT<20: 79%; BCT>20: 36%), including >300/µM in 27% (BCT<20: 43%; BCT>20: 10%); baseline ASAT level was >1000 IU in 38% (BCT<20: 77%; BCT>20: 17%); and baseline Creatine Kinase level >4000 IU in 18% (BCT<20: 24%; BCT>20: 8%). The figure shows the PCR CT values at baseline (D0) and at D2 and D4 following treatment initiation. Overall, 48% of participants died (BCT<20: 85%; BCT>20: 15%). The pre-trial mortality was 58% overall (p=0.15), 85% in patients with BCT<20 (p=0.26) and 30% in patients with BCT>20 (p=0.05). Mortality was 100% and 7% in patients with abnormal baseline creatinine values and BCT <20 or >20, respectively. The drug was well tolerated. Results of quantitative virology and PK tests will be available later.



Conclusions: In this non comparative proof of concept trial, most patients with CT< 20 had severe kidney failure and died, with no indication that favipiravir monotherapy improved survival. Patients with CT>20 had a lower mortality rate compared to pre-trial figures in the same settings. These preliminary data encourage continued testing of favipiravir with particular attention to identifying patients earlier in disease course, and to explore other therapeutic options, including combinations, in patients who present at advanced stages.

Session O-9 Oral Abstracts — Room 6D

10:00 am – 12:15 pm

New Insights Into HIV Persistence, Latency Reversal, and Viremia Rebound

104LB Durable Control of Viral Rebound in Humanized Mice by ABX464 Targeting Rev Functions

Noelie Campos[1]; Renier Myburgh[3]; Aude Garcel[1]; Audrey Vautrin[2]; Laure Lapasset[2]; Katjana Tantale[2]; Mark Wainberg[4]; Roberto Speck[3]; Didier Scherrer[1]; **Jamal Tazi**[2]

[1]ABIVAX, Montpellier, France; [2]University of Montpellier, Montpellier, France; [3]University of Zurich, Zurich, Switzerland; [4]McGill AIDS Center, Montréal, Canada

Background: Current therapies have succeeded in controlling AIDS pandemic. However, there is a continuing need for new drugs, in particular those acting through new and as yet unexplored mechanisms of action to achieve HIV infection cure. We took advantage of the unique feature of proviral genome to require both activation and inhibition of splicing of viral transcripts to develop molecules capable of achieving long lasting effect on viral replication through inhibition of rev-mediated viral RNA biogenesis

Methods: A dedicated library was designed and synthesized to modulate HIV RNA splicing (**WO2012080953, June 2012)** . The library was screened on infected PBMCs from healthy donors and ABX464 was selected.

Deep sequencing of viral RNA from treated cells established that ABX464 does not select for mutations, however, induced massive splicing of viral RNA.

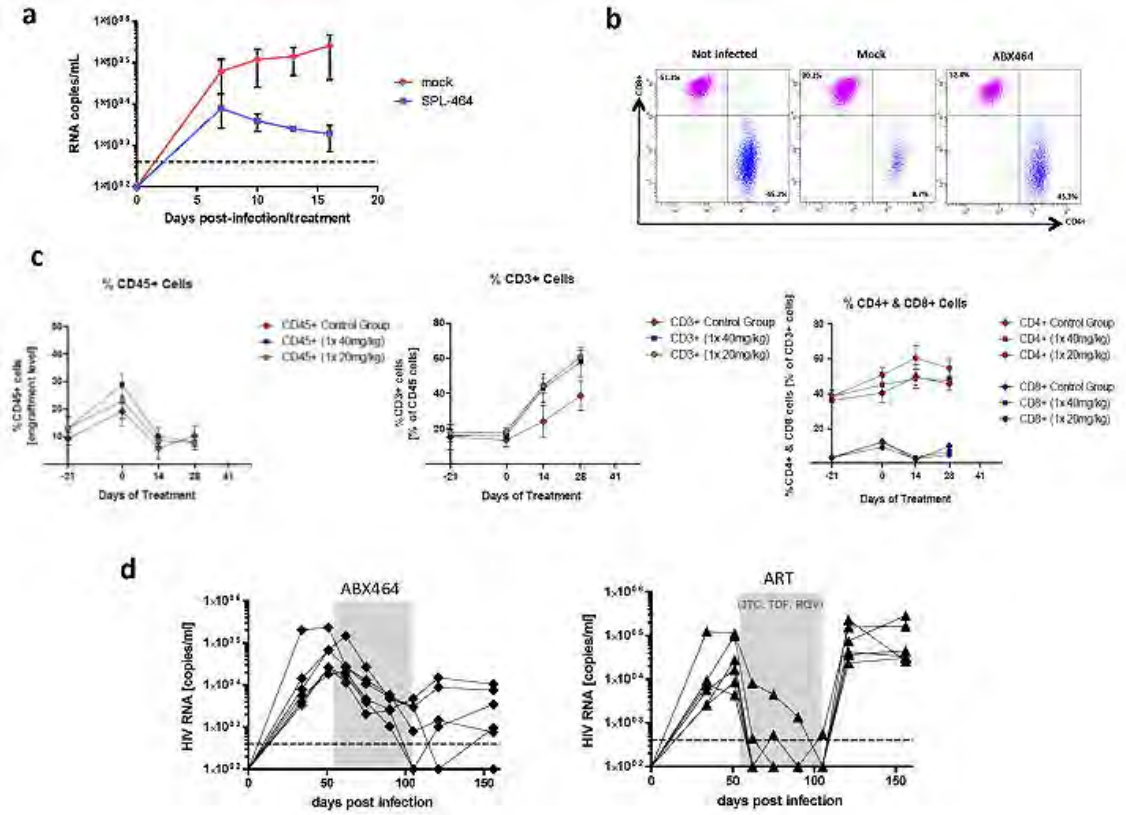
Using a system to visualize single HIV RNA molecules in living cells, we established that ABX464 interferes with Rev-mediated RNA biogenesis.

Two humanized mouse models were used to test the efficacy of ABX464 *in vivo;* SCID mice reconstituted with PBMCs and newborn NOG mice transplanted with CD34+ haematopoietic progenitor cells isolated from umbilical cord blood.

Results: ABX464 compromises HIV replication of clinical isolates of different subtypes without selecting for drug resistance in PBMCs or macrophages. ABX464 inhibits viral replication by preventing Rev-mediated export of unspliced HIV-1 transcripts to the cytoplasm. Retained viral RNA is massively spliced but normal cellular splicing is unaffected by the drug.

ABX464 alone, also efficiently compromised viral proliferation in two humanized mouse models infected with HIV that require a combination of 3TC, Raltegravir and tenofovir (ART) to achieve viral inhibition in current protocols. Crucially, there was no rebound of viral load for two months following treatment cessation of ABX464 whereas viral load increased dramatically just one week after ART treatment.

A phase I study conducted in healthy volunteers has demonstrated that a single administration of ABX464 was well tolerated up to 150 mg.



(a) Reconstituted SCID mice were infected with JRCSF HIV-1 strain by intraperitoneal injection. Control group received by gavage labrafil and 5% DMSO (n=15) and treated group 20mg/kg b.i.d of ABX464 in labrafil and 5% DMSO (n=14) for 15 days. (b) FACS analysis was performed on peritoneal wash at day 15 post-treatment to assess the CD8/CD4 ratio. (c) Engrafted NSG humanized mice were treated by oral gavage with ABX464 at either 20 mg or 40 mg/kg once a day for 30 days and indicated lymphocyte populations were monitored by FACS analysis. (d) NSG humanized mice were infected with the YU2 HIV-1 virus and treated either by oral gavage with SPL-464 at 40 mg/kg once a day for 30 days or by HAART (3TC-Tenofovir-Raltegravir and AZT).

Conclusions: ABX464 represents a novel class of anti-HIV molecules with unique properties. ABX464 has a long lasting effect in humanized mice and neutralizes the expression of HIV-1 proviral genome of infected immune cells including reservoirs and it is therefore a promising drug toward HIV cure.

105 Residual Viremia Caused by Clonally Expanded Tumor-Infiltrating CD4+ Cells

Francesco R. Simonetti[1]; Michele D. Sobolowski[2]; Shawn Hill[1]; Wei Shao[3]; Elizabeth Fyne[2]; Xiaolin Wu[1]; John M. Coffin[4]; Stephen H. Hughes[1]; John W. Mellors[2]; Frank Maldarelli[1]

[1]National Cancer Institute (NCI), Frederick, MD, US; [2]University of Pittsburgh, Pittsburg, PA, US; [3]Frederick National Laboratory for Cancer Research, Frederick, MD, US; [4]Tufts University, Boston, MA, US; [5]National Cancer Institute (NCI), Frederick, MD, US

Background: Clonal expansion of infected cells can contribute to HIV-1 persistence. We recently reported that a clonally-expanded population of HIV-infected cells was responsible for persistent viremia despite ART in a patient with metastatic squamous cell carcinoma (Maldarelli, et al., 2014). We conducted extensive ante- and post-mortem analysis of HIV-infected cells from this patient to investigate the organ and tumor distribution of this clonal variant.

Methods: Plasma and peripheral blood mononuclear cells (PBMC) were obtained ante mortem, and samples from spleen, ileum, rectum, 5 lymph nodes, and 5 tumor metastases were obtained at autopsy. Tissues were characterized by histo- and immunohistochemistry and qPCR of the genomic DNA was used to measure the levels of HIV *gag* sequences. A new single genome sequencing assay was performed to amplify the 800bp nef-U3 region from blood and tissues. Integration site flanking sequences were used to PCR amplify the full length of expanded proviruses. An ex-vivo infectious virus recovery assay was developed to characterize inducible HIV variants from PBMC-derived CD4+ cells. Sequences were subjected to phylogenetic and statistical analyses.

Results: HIV sequences (N=317) were recovered from plasma, PBMC, spleen, lymph nodes, and tumor tissues, which were infiltrated with both CD4+ and CD8+ T cells. In general, HIV variants were well mixed across blood and tissues and there was no evidence of localized replication. One provirus from a highly amplified clone (AMB-1), known to produce the majority of the HIV RNA detected in plasma, was enriched in tumor tissues. AMB-1 proviruses were present in each tumor metastasis, with an overall abundance in tumor tissue significantly (3.5-fold) greater than that detected in lymphoid tissues (p=0.0005). The full length AMB-1 sequence revealed an intact provirus and no drug resistance mutations. AMB-1 RNA was recovered in day 7 culture supernatants after stimulation (PHA, irradiated blasts) and co-culture of CD4+ T-cells with CD8-depleted allogeneic blasts but declined with continued culture associated temporally with outgrowth of other variants.

Conclusions: This study is the first report of residual viremia caused by an expanded cell carrying a specific intact HIV provirus. Cells from this clone accumulated specifically in cancer metastases. These observations suggest that immune stimuli, like tumor antigens, can contribute to cell expansion, and perhaps to the activation of the provirus and release of virions into plasma.

106 Analysis of HIV RNA in Single Cells Reveals Clonal Expansions and Defective Genomes

Ann Wiegand[1]; Jonathan Spindler[1]; Wei Shao[2]; Feiyu Hong[3]; Anthony R. Cillo[3]; Elias Halvas[3]; Elizabeth Fyne[3]; John M. Coffin[4]; John W. Mellors[3]; **Mary F. Kearney**[1]

[1]National Cancer Institute, Frederick, MD, MD, US; [2]Leidos, Frederick, MD, US; [3]University of Pittsburgh, Pittsburgh, PA, US; [4]Tufts University, Boston, MA, US

Background: Little is known about HIV-1 provirus expression in patients on suppressive ART. Characterizing cell-associated RNA (CAR) sequences in single cells can reveal their relationship to proviral populations and to persistent viremia. Here, we describe a new, sensitive method to assess the genetics of HIV CAR in viremic and virologically suppressed patients.

Methods: HIV-1 CAR was extracted from 4-6 separate aliquots of PBMCs from 3 patients using methods that were verified (by spiking known quantities of ACH2 cells into HIV negative PBMCs) to have high recovery of HIV-1 DNA and RNA. DNase-treatment and cDNA synthesis were optimized to ensure complete degradation of HIV DNA and high efficiency of long cDNA synthesis. Products were diluted to <1 HIV cDNA molecule/reaction, amplified, and sequenced (CAR-SGS). In patients who initiated ART with high HIV diversity, identical RNA sequences from the same aliquot of PBMCs were assumed to be derived from the same cell expressing HIV RNA, while identical sequences in different aliquots were assumed to be derived from clonally expanded, expressing cells. Single-genome sequences of proviral DNA and plasma HIV-1 RNA were compared to CAR sequences using standard bioinformatics methods.

Results: We developed and optimized methods for CAR-SGS to be used to profile cellular HIV-1 RNA expression in patients. 3 patients were studied: 1 was untreated and viremic and 2 were suppressed on ART. An average of 41 single cells per patient was analyzed. We found 53% of the HIV expressing cells in the viremic patient to be "high producers" (more than one RNA molecule detected) and 30% to be high producers in the suppressed patients. The diversity of the total RNA populations both before and during ART was ~1% in *pro-pol*, and G to A hypermutants were detected in the suppressed patients at similar levels to their proviral DNA populations (20% and 22%). We also detected HIV-1 expression from clonally expanded populations in one suppressed patient.

Conclusions: A new method to characterize the expression of HIV-1 proviruses that persist during ART reveals high levels of expression of RNA from infected individuals as well as clonally expanded cells. Further studies are needed to determine if HIV-1 expression results from spontaneous reactivation from latency or continuous low-level virus transcription and if these cells can be the source of viral rebound when ART is interrupted.

107 Low-Level HIV Viremias Originate in Part From Infected Proliferating Cells

Marta E. Bull[1]; Sherry McLaughlin[2]; Hannah Huang[2]; Sheila Styrchak[2]; Jaime Soria[3]; Eduardo Ticona[3]; Alberto La Rosa[4]; Caroline Mitchell[5]; James Mullins[1]; Lisa Frenkel[1]

[1]University of Washington, Seattle, WA, US; [2]Seattle Children's Research Institute, Seattle, WA, US; [3]Hospital Nacional dos de Mayo, Lima, Peru; [4]Investigaciones Médicas en Salud (INMENSA), Lima, Peru; [5]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, US; [6]University of Washington, Seattle, WA, US

Background: Understanding mechanisms that allow HIV infection to persist despite suppressive antiretroviral therapy (**ART)** may help develop cure strategies. We observed that cells with HIV integrated into genes associated with cell proliferation or cancer form persistent clones, defined as multiple cells with identical proviruses (HIV *env* C2-V5) and with identical integration sites (**IS**). We hypothesized that these cell clones can produce virions, evident as low-level viremias (**LLV**).

Methods: A subset of HIV-infected ART-naïve subjects, enrolled into a 2-year observational study just before the initiation of nevirapine-based ART, were selected for this study based on detection of LLV (40-500 copies/mL) after one-year of suppressive (<40 copies/mL) ART. Samples were collected every 3 months over the 2 year study. HIV *env* (C2-V5) sequences were derived from peripheral blood mononuclear cells (**PBMC**) and plasma prior to starting ART and at a single LLV visit by single-genome-analysis (**SGA**). Multiple chromosomal IS and associated HIV *env* sequences were generated using an integration site looping assay (**ISLA**) (PMID25011556) from PBMC at the LLV visit that was diluted to a median single infected cell. IS were aligned using Bowtie and the location in the human genome determined using BLAT. HIV *env* sequences from LLV and PBMC were aligned with MUSCLE, and phylogenetic trees generated using DIVEIN. The proportion of LLV with *env* sequences identical to those in infected proliferating PBMC were evaluated by Fisher's exact test and distances from most recent common ancestor (**MRCA)** were evaluated by Wilcoxon signed rank test.

Results: Eight participants had LLV on 21/64 study visits. A median of 21 *env* sequences (range 19-28) were generated from a single LLV, and 90% were identical within a subject. A total of 287 IS sequences were generated from PBMC samples at the LLV visit (median 42 IS/subject, range 27-47). Proliferation of infected cells, evident from multiple cells with identical IS, was observed in 6/8 subjects. Two of these six subjects had proliferating clones with *env* sequences identical to those in LLV. Three of the six subjects with LLV sequences without linkage to proliferating PBMC had evidence of ongoing viral evolution, and hence continuing viral replication.

Conclusions: Clones of HIV-infected PBMC that persist during suppressive ART are capable of producing virions. LLV appear to originate from virion expression from proliferating infected cell clones or from low–level replication.

108 Treatment With a TLR7 Agonist Induces Transient Viremia in SIV-Infected ART-Suppressed Monkeys

James B. Whitney[1]; So-Yon Lim[1]; Christa E. Osuna[1]; Srisowmya Sanisetty[1]; Tiffany L. Barnes[2]; Peter T. Hraber[3]; Tomas Cihlar[2]; Romas Geleziunas[2]; Joseph Hesselgesser[2]

[1]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, US; [2]Gilead Sciences, Inc., Foster City, CA, US; [3]Los Alamos National Laboratories, Los Alamos, NM, US

Background: Latent reservoirs of replication competent HIV-1 persist in patients on antiretroviral therapy (ART) and represent the major obstacle to HIV eradication efforts. Considerable effort has been directed to identify pharmaceutical agents capable of safely reactivating latent HIV-1 in ART-suppressed patients.

Methods: A study was conducted in SIV-infected rhesus macaques (RM) on ART to determine if administration of an oral toll-like receptor 7 (TLR7) agonist would induce transient plasma viremia and reduce viral reservoirs. Ten RM were infected with SIVmac251 by rectal challenge. Plasma SIV RNA levels were measured by RT-PCR (limit of detection 50 copies/mL). The RM received ART at ~9 weeks post-infection (PI) and became virologically suppressed by 24 weeks PI; virologic suppression was maintained through week 45. At 45 weeks PI, 4 RM were administered 7 doses of the TLR7 agonist at twice monthly intervals, while on ART. The first 3 doses were 0.1, 0.2 and 0.3 mg/kg and the last 4 doses remained constant at 0.3 mg/kg. Total viral DNA was quantified in peripheral blood mononuclear cells (PBMC), colon and lymph node biopsies taken pre- and post-completion of TLR7 treatment. Two weeks after TLR7 dosing, ART was discontinued.

Results: The first 3 doses of TLR7 agonist administered to the SIV-infected ART-suppressed RM had limited effect on plasma viremia. However, doses 4 through 7 led to transient and consistent increases in plasma virus (500 - 1000 SIV RNA copies/mL) in all treated RMs with a return to < 50 copies/mL within 4-7 days of TLR7 dosing. After completion of the TLR7 regimen, SIV DNA levels were reduced by 56-75% in PBMC, colon and lymphoid tissues. Viral DNA levels remained unchanged in the placebo control RM. To determine if these transient plasma virus blips and decreases in viral DNA content also reduced the size of the viral reservoir, ART was discontinued. While the plasma virus rebound kinetics in animals dosed with the TLR7 agonist were comparable to the placebo group after discontinuation of ART, the TLR7 treated animals showed a ~0.5 $\log_{10}$ reduction in plasma virus setpoint as compared to the placebo group.

Conclusions: Multiple oral administrations of a TLR7 agonist in SIV-infected ART-suppressed RM was safe, induced transient plasma viremia, reduced viral DNA content in PBMCs, colon and lymphoid tissues and established lower viral setpoint after ART cessation. These novel findings support clinical investigation of a TLR7 agonist in HIV-1 infected patients on ART.

109 Panobinostat Broadly Activates Latent HIV-1 Proviruses in Patients

Kirston M. Barton[1]; Thomas A. Rasmussen[2]; Martin Tolstrup[2]; Wei Shao[4]; Bonnie Hiener[1]; Ajantha Solomon[3]; Lars Østergaard[2]; Sharon R. Lewin[3]; Ole Søgaard[2]; **Sarah E. Palmer**[1]

[1]Westmead Millennium Institute and University of Sydney, Westmead, Australia; [2]Aarhus University Hospital, Aarhus, Denmark; [3]Doherty Institute for Infection and Immunity, Melbourne, Australia; [4]National Cancer Institute, Rockville, MD, US

Background: To target the persistence of quiescent HIV-1 during ART, HDAC inhibitors have been used to induce viral transcription, which could potentially facilitate viral clearance. It is important that all replication competent proviruses are activated to fully purge infection. Therefore, we performed an in-depth analysis of the panobinostat clinical trial to determine whether the observed increases in unspliced cell-associated RNA (CA RNA) were due to transcription from a subset or a broad range of proviruses.

Methods: Panobinostat was administered to 15 patients on suppressive ART three times a week every other week for eight weeks (i.e., four cycles of drug). Cell-associated DNA (CA DNA) and RNA were extracted from PBMCs collected before, twice while receiving and four weeks after the final dose of panobinostat treatment. Additionally, plasma samples were collected prior to initiation of ART (nine patients) and during a post-panobinostat analytical treatment interruption (ATI, nine patients) to assess circulating HIV-1. Single-genome sequencing of the env region was used to characterise the virus from the cell-associated DNA and RNA and plasma RNA.

Results: The sequences obtained from the preART plasma reflected the infection status of the patient (acute vs. chronic). Phylogenetic analysis revealed that the panobinostat-induced viral RNA intermingled extensively with the CA DNA sequences from the equivalent time points, indicating that panobinostat activates transcription from a broad range of proviruses. The rebound virus from the ATI plasma was composed of expansions of homogenous sequences, and the sequences from this virus were genetically similar to the panobinostat-induced CA RNA sequences. Furthermore, CA DNA sequences that were identical to the rebound virus were detected. A significantly higher percentage of the sequences from the CA RNA were hypermutated compared to the CA DNA (p=0.04).

Conclusions: Panobinostat non-selectively activates transcription from quiescent proviruses in patients on suppressive ART, supporting its ability to activate HIV-1 from latency. Furthermore, panobinostat activated virus that was genetically similar to that observed during ATI, indicating that it targets virus that drives rebound following treatment discontinuation. The high percentage of hypermutated HIV CA RNA that was detected stresses the need for assays that measure replication competent virus when assessing latency reversing agents.

110LB The Size of the Active HIV Reservoir Predicts Timing of Viral Rebound

Behzad Etemad[1]; Hayat Ahmed[1]; Evgenia Aga[2]; Ronald Bosch[2]; John W. Mellors[3]; Daniel Kuritzkes[1]; Michael Para[4]; Rajesh T. Gandhi[5]; **Jonathan Li**[1]

[1]Brigham and Women's Hospital, Harvard Medical School, Cambridge, MA, US; [2]Harvard School of Public Health, Center for Biostatistics in AIDS Research, Boston, MA, US; [3]University of Pittsburgh, Pittsburgh, PA, US; [4]Ohio State University, Columbus, OH, US; [5]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US

Background: Strategies to achieve sustained ART-free HIV remission will require validation in analytic treatment interruption (ATI) trials. Identifying virologic biomarkers that can predict time to viral rebound could accelerate the development of such therapeutics. We examined the association of pre-ATI cell-associated RNA (CA-RNA), DNA (CA-DNA), and residual viremia (RV) with timing of viral rebound during ATI.

Methods: We performed a retrospective combined analysis of participants from 5 ACTG studies who were virologically suppressed on ART and received no immunologic intervention prior to undergoing ATI. The timing of viral rebound was evaluated at either (1) confirmed viral load ≥200 HIV RNA copies/mL or (2) single viral load ≥1,000 HIV RNA copies/mL. Unspliced CA-RNA and CA-DNA were quantified using qPCR, and RV by the single-copy assay.

Results: Participants who initiated ART during acute/early infection (n=20) had lower levels of pre-ATI CA-RNA than those treated during chronic infection (n=104) (median <1.58 vs. 1.83 $\log_{10}$ HIV-1 RNA copies/10^6 PBMCs, P<0.01). No significant differences were seen in pre-ATI levels of CA-DNA or RV between those treated during acute/early vs. chronic infection. There were no significant differences by ART regimen (NNRTI vs. PI-based) in pre-ATI CA-RNA, CA-DNA, or RV. Higher pre-ATI CA-RNA levels were significantly associated with shorter time to viral rebound using a threshold of either 200 HIV-1 RNA copies/mL (≤4 wks [N=75] vs. 5-8 wks [N=35] vs. >8 wks [N=14]: 1.83 vs. 1.68 vs.<1.58 $\log_{10}$ HIV-1 RNA copies/10^6 PBMCs, Kruskal-Wallis P<0.01] or 1,000 HIV-1 RNA copies/mL (1.83 vs. 1.69 vs. <1.58 $\log_{10}$ HIV-1 RNA copies/10^6 PBMCs, P<0.01). The proportion of participants with detectable RV ≥1 copy/mL was significantly higher in those with shorter time to ≥200 HIV-1 RNA copies/mL (≤ 4 wks vs. 5-8 wks vs. ≥8 wks: 47% vs. 29% vs. 8%, Fisher's P=0.02]. No significant association was seen between CA-DNA levels and timing of viral rebound. A modest correlation was detected between levels of pre-ATI CA-RNA and CA-DNA (Spearman r=0.16, P=0.08).

Conclusions: The size of the active HIV reservoir, as reflected by levels of CA-RNA and RV, is associated with the time to viral rebound after interrupting ART. CA-RNA and RV have the potential to serve as biomarkers of efficacy for therapies aiming to achieve sustained ART-free HIV remission.

111LB Biomarkers to Predict Viral Rebound at Antiretroviral Therapy Interruption in SPARTAC

Jacob Hurst[1]; James Williams[1]; John P. Thornhill[2]; Matthew Pace[1]; Chris Willberg[1]; Elizabeth Hamlyn[3]; Abdel Babiker[4]; Rodney Phillips[1]; Sarah Fidler[2]; **John Frater**[1]
on behalf of the SPARTAC Trial Investigators

[1]University of Oxford, Oxford, United Kingdom; [2]St Mary's Hospital–Imperial College Healthcare NHS Trust, London, United Kingdom; [3]King's College London, London, United Kingdom; [4]Medical Research Council Clinical Trials Unit, London, United Kingdom

Background: Treatment of HIV-1 infection with antiretroviral therapy (ART) in the first few weeks or months following transmission may induce a state of virological remission or 'post-treatment control' (PTC), in which viraemia remains suppressed when ART is stopped. We present an analysis of 18 immunological and virological biomarkers measured in primary HIV-1 infection (PHI) to determine if they may help predict PTC after treatment interruption (TI).

Methods: We retrospectively analysed a sub-group of samples from SPARTAC - a randomised controlled study of PHI incorporating a TI after 48 weeks of ART. We measured HIV-1 specific CD4 and CD8 T cell ELISpot responses, markers of T cell activation (HLA DR, CD38, CD25, CD69) and exhaustion (Tim-3, Lag-3, PD-1, TIGIT), soluble markers (Il-6, d-dimer), HIV-1 DNA (Total and Integrated), cell-associated unspliced RNA, CD4 count, plasma viral load and the CD4/CD8 ratio. Statistical analyses explored associations between biomarkers and Total HIV-1 DNA and time to viral rebound at TI, with measurements taken, where samples permitted, pre-therapy in all participants and at 48 weeks in those undertaking TI.

Results: We analysed 154 individuals prior to starting ART, a median of 73.8 days from the estimated date of seroconversion. 47 participants undertook a TI after 48 weeks of ART. In univariable regression models undertaken with samples from pre-therapy baseline, CD4/CD8 ratio, CD4 count, plasma viral load, CD8 CD38, CD8 PD-1, CD8 HLA DR, CD4 HLA DR, CD8 Lag-3 and d-dimer were significantly associated (all $P<0.05$) with HIV-1 DNA levels, but only CD4 count, viral load, CD8 CD38, CD8 Lag-3 and d-dimer survived in multivariable analyses.

When measured pre-therapy, and adjusting for levels of HIV-1 DNA, T cell exhaustion marker expression on CD4 (PD-1, Tim-3 and Lag-3) and CD8 (Tim-3 only) T cells predicted time to the return of viraemia (n=20; Table 1), but notably not when measured at TI. Apart from Total HIV-1 DNA, in this sub-group analysis we found no evidence for any other biomarkers associating with rebound when measured at baseline or at TI.

T cell	Biomarker	Association with time to rebound* (HR [CI]; p-value)
CD4+	PD-1	1.46 [1.06-1.85]; p=0.016
	Tim-3	1.36 [1.16-1.60]; p=0.009
	Lag-3	1.08 [1.02-1.15]; p=0.007
CD8+	Tim-3	1.15 [1.06-1.26]; p=0.001

Table 1: T cell exhaustion markers pre-therapy are associated with time to viral rebound at TI. *Multivariable Cox model adjusting for the biomarker and Total HIV-1 DNA. HR: Hazard ratio; CI: 95% confidence interval

Conclusions: In the search for an algorithm of biomarkers to help stratify treated PHI patients according to likelihood of PTC, these data indicate that pre-therapy measurements may be informative and that markers of T cell exhaustion should be included alongside HIV-1 DNA levels. This may also open critical new avenues for understanding the mechanisms underlying PTC, which need to be explored in larger cohorts.

112LB HIV-1 Diversity and Tropism of Rebound Virus After Treatment Discontinuation

Maria M. Bednar[1]; Blake Hauser[1]; Jeffrey M. Jacobson[2]; Ian Frank[4]; Joseph J. Eron[3]; Ronald Swanstrom[1]
On behalf of the NWCS 379 team

[1]University of North Carolina, Durham, NC, US; [2]Drexel University College of Medicine, Philadelphia, PA, US; [3]University of North Carolina, Chapel Hill, NC, US; [4]University of Pennsylvania, Philadelphia, PA, US

Background: Suppressive antiviral therapy has not been successful in eliminating virus, as patients on suppressive therapy retain a persistent, measurable, stable low-level viremia (LLV), and people discontinuing therapy see a rebound of virus from a persistent reservoir, as seen in the ACTG study A5068. ACTG study A5068 was designed to determine the efficacy of structured treatment interruptions and/or vaccination with an ALVAC-HIV vector for controlling viral replication after therapy discontinuation. Arm A (n=24) received neither STI nor vaccination, virologic rebound was detectable 2-4 weeks after discontinuation of therapy, and reached a peak several weeks later. We have used single genome amplification (SGA) of the viral *env* gene to assess genetic diversity followed by cloning to examine the tropism of the rebound virus by performing tropism assays to determine if the virus was adapted to grow in T cells (requiring high levels of CD4) or adapted to grow in macrophages (able to enter cells with low levels of CD4).

Methods: Viral RNA was isolated from the first available blood plasma sample containing viral load >1000 copies/mL from subjects infected with subtype B HIV-1 who had stopped therapy (10 total). We performed SGA to isolate individual *env* gene amplicons, 51 of which were cloned (average of 4 amplicons per tree) and infectivity analyzed at varying CD4 levels using Affinofile cells, in order to determine the viral entry phenotype for CD4 usage.

Results: Phylogenetic analysis of the viral *env* genes showed low diversity in each subject, consistent with an initially clonal repopulation of the viral population during rebound. No evidence of macrophage-tropic virus was found meaning that all of the rebound *env* genes tested encoded proteins that required high levels of CD4 for efficient entry of pseudotyped virus into Affinofile cells.

Conclusions: The source of the rebound virus is poorly understood, with the current model assuming this virus comes from resting CD4+ T cells; however, other cell types could be the source of this virus. Our analysis further excludes a myeloid cell source, where virus was persistently infecting these cells prior to therapy. Such a virus would have adapted to be able to use low levels of CD4, and this type of virus was not detected as the rebound virus. While our analysis does not identify the cell type harboring the virus that initiated the rebound, it is consistent with a CD4+ T cell as the source of the virus.

Themed Discussion Abstracts

188 HIV-1 Exploits CD169 to Evade IFNα-Induced Antiviral State in Myeloid Cells

Hisashi Akiyama[1]; Nora Ramirez[1]; Gregory Gibson[2]; Simon Watkins[2]; Zandrea Ambrose[2]; Rahm Gummuluru[1]

[1]Boston University School of Medicine, Boston, MA, US; [2]University of Pittsburgh School of Medicine, Pittsburgh, PA, US; [3]University of Pittsburgh School of Medicine, Pittsburgh, PA, US

Background: A hallmark of HIV-1 infection in vivo is chronic immune activation concomitant with type I interferon (IFN-I) production. Although IFN-Is induce an antiviral state in many cell types, HIV-1 can replicate even in the presence of IFN-Is in vivo. We have recently identified the IFN-I-inducible protein CD169 as an HIV-1 receptor on myeloid dendritic

cells that can mediate robust infection of $CD4^+$ T cells in trans. Since CD169 expression is also induced by IFN-Is on macrophages, we hypothesized that CD169 induced by IFN-I could facilitate productive HIV-1 infection in macrophages in cis and thus offset antiviral effects of IFN-Is.

Methods: To investigate the effect of IFN-Is on HIV-1 replication in myeloid cells, a monocyte cell line, THP-1 or primary monocyte-derived macrophages (MDMs) were treated with IFNα for 48 hours and infected with HIVΔenv-luc reporter virus pseudotyped with HIV-1 Lai (HIV/Lai) or VSV-G (HIV/G) glycoproteins, or replication competent HIV-luc. HIV-1 fusion was measured by the conventional Vpr-BlaM assay. To investigate if $CD169^+$ myeloid cells are productively infected in vivo, lymph nodes (LNs) from pigtailed macaques chronically infected with RT-$SHIV_{mne027}$ were stained for $p27^{gag}$ and CD169.

Results: As reported previously, HIV/G infection was severely attenuated in IFN-treated-THP-1. Surprisingly, however, replication of HIV/Lai was enhanced in IFN-treated-THP-1 than in untreated THP-1. We found that HIV/Lai fusion was greatly enhanced in IFN-treated-THP-1, while that of HIV/G was severely attenuated. This enhanced fusion and infection depended on CD169 since pretreatment with αCD169 blocking antibody abrogated the enhancement of virus fusion and replication in IFN-treated-THP-1. IFNα treatment of MDMs also up-regulated CD169 and HIV-1 fusion in treated MDMs was enhanced (2-fold) in a CD169-dependent manner. Interestingly, CD169 enhanced virus replication in MDMs even in the presence of IFNα (>2-fold higher compared to MDMs pretreated with αCD169 blocking antibody). Finally, LNs from SHIV-infected macaques showing signatures of immune activation contained more $CD169^+$ cells than those of uninfected animals and, intriguingly, a large proportion of $p27^{gag+}$ cells were also $CD169^+$.

Conclusions: These studies suggest that HIV-1 has exploited CD169 to attenuate IFN-I-induced antiviral state in myeloid cells.

192 HIV and SIV Inhibition by RNA-Associated Early Stage Antiviral Factor (REAF)

Aine McKnight
Queen Mary University of London, London, United Kingdom

Background: The interaction of viruses with their human host is a constant war. The discovery of novel anti-viral restriction factors illuminates unknown aspects of innate sensing and immunity.

Methods: An siRNA screen of ~20,000 human genes was used to uncover those involved in inhibition of HIV replication. We identified RNA-associated Early-stage Anti-viral Factor (REAF) as an inhibitor of HIV replication

Results: 114 genes were identified to be potentially involved in intrinsic resistance. Focusing on the most potent factors led us to REAF. REAF (previously RPRD2) was annotated in the human genome but with no known function. We observed more than 50 fold rescue of HIV-1 infection following knockdown of REAF by specific siRNA. Quantitative PCR was used to measure the effect of REAF knockdown on two steps in the replication cycle – production of reverse transcripts and integration of viral cDNA. Both steps were strongly enhanced. Conversely, when REAF is over expressed in target cells fewer reverse transcripts are produced. Human REAF can also inhibit HIV-2 and simian immunodeficiency virus (SIV) infection. REAF interacts (either directly or indirectly) with HIV RNA or RNA:DNA intermediates during reverse transcription. Also, during the process of reverse transcription REAF protein is degraded, within one hour of infection, in a proteosomal dependent manner.

Furthermore, REAF can inhibit HIV replication via different routes of entry into cells. Its potency is, however, highly dependent on the pathway of entry used and we show it is the lentiviral restriction factor 2 (Lv-2) [1,2].

Conclusions: We propose that REAF is part of an anti-viral surveillance system destroying incoming retroviruses. This novel mechanism could apply to invasion of cells by any intracellular pathogen.

1 Marchant, D., Neil, S. J., Aubin, K., Schmitz, C. & McKnight, A. An envelope-determined, pH-independent endocytic route of viral entry determines the susceptibility of human immunodeficiency virus type 1 (HIV-1) and HIV-2 to Lv2 restriction. *J Virol* **79**, 9410-9418, (2005).

2 Schmitz, C., Marchant, D., Neil, S. J., Aubin, K., Reuter, S., Dittmar, M. T. & McKnight, A. Lv2, a novel postentry restriction, is mediated by both capsid and envelope. *J Virol* **78**, 2006-2016, (2004).

184 Regulation of the Innate Immune Sensing of HIV by the Viral Capsid and the Cytosolic DNA Sensor cGAS

Nicolas Manel
Institut Curie, Paris, France

Background: Dendritic cells (DCs) play an important role in the detection of viral infections through innate sensing pathways and the induction of immune responses. The pathogenic virus HIV-1 escapes cytosolic innate immune sensing by monocyte-derived DCs. Innate sensing of HIV-1 by DCs can be rescued by complementing the virus with the small protein Vpx found in HIV-2, attributing the lack of cytosolic sensing of HIV-1 to to the poor ability of the virus to replicate in MDDCs as a result of the SAMHD1 restriction. In contrast, VSV-G-pseudotyped HIV-2 efficiently infects MDDCs and activates pathways of innate immunity. HIV-2 is much less pathogenic than HIV-1, suggesting that such recognition by DCs may be important for effective anti-HIV immune responses. However, the mechanism of cytosolic HIV sensing by DCs remained to be determined.

Methods: Initial experiments showed that the viral capsid and its interaction with the cellular protein Cyclophilin A plays an important role. To study HIV sensing, we designed mutations in capsid to increase its affinity for Cyclophilin A (HIVac).

Results: Strikingly, HIVac mutated viruses maintained the ability to activate DCs but had lost the ability to infect the DCs. Using such virus, we found that innate sensing requires synthesis of the viral cDNA, but not nuclear entry and genome integration. We also find that the wild-type HIV-1 capsid normally shields the cDNA before genome integration, preventing its detection by innate sensor(s). Finally, we examined cytosolic DNA sensors using RNAi. We find that the cytosolic DNA sensor cGAS (cyclic GMP-AMP synthase) is required for innate recognition of HIV-1 and HIV-2 cDNA by DCs.

Conclusions: Altogether, these results establish that cGAS is an important innate sensor of HIV-1 and HIV-2 and uncover an essential regulation of this sensing mechanism by capsid and Cyclophilin A. We are currently investigating various aspects of these innate immune mechanisms and new findings will be presented.

203 Mapping Vpx and Vpr Specificity in Antagonism of SAMHD1

Chelsea Spragg; Michael Emerman
Fred Hutchinson Cancer Research Center, Seattle, WA, US

Background: The lentiviral accessory protein Vpx enhances infectivity of macrophages, dendritic cells, and resting T-cells by inducing degradation of the restriction factor SAMHD1, which blocks replication at reverse transcription. Vpx bridges SAMHD1 to the host ubiquitin ligase substrate receptor DCAF1, leading to polyubiquitination of SAMHD1 and degradation by the proteasome. The *vpx* gene is present in only two major lineages of lentivirus including HIV-2, but the paralagous *vpr* is present in all extant lineages. In certain cases, Vpr also has the ability to degrade host SAMHD1. SAMHD1 has evolved under positive selection due to viral antagonism, resulting in species-specificity between host SAMHD1 and viral Vpx/r. Depending on the lineage, Vpx exclusively targets either the N-terminus or the C-terminus of SAMHD1; however, the regions of Vpx/r controlling specificity

are unknown. The structure of SIVmac Vpx bound to DCAF1 and the C-terminus of SAMHD1 has been solved, but there is extreme sequence diversity in *vpr* and *vpx* from divergent viruses.

Methods: We used an evolutionary and structural approach to find appropriate and robust breakpoints in Vpx and Vpr in order to create functional, chimeric viral proteins. By assaying for the gain of ability to degrade resistant SAMHD1, these chimeric proteins assisted in mapping of determinants of specificity in Vpx and Vpr from several lentiviral lineages.

Results: We found that the majority of residues involved in binding DCAF1 were conserved in essentially all SAMHD1-degrading Vpx and Vpr. We identified highly conserved amino acids flanking the regions of SIVmac Vpx involved in binding SAMHD1. These conserved motifs served as breakpoints to create chimeric proteins between Vpr and Vpx from SIVs infecting macaque, red-capped mangabey, and African green monkeys. We were then able to retarget Vpx and Vpr from different lentiviruses to degrade heterologous SAMHD1. Depending on the lineage, the specificity of Vpx/r in degrading SAMHD1 maps to one or two regions in the viral protein.

Conclusions: The structure of Vpx and Vpr proteins and their interaction with the host ubiquitin ligase is widely conserved, despite high levels of sequence variation across lineages. Given the evolutionary constriction in maintaining this ubiquitin ligase binding, similar regions of Vpr/x are used to target SAMHD1, allowing the mapping of sites that govern SAMHD1 antagonism in species-specific interactions.

202 A Surprising New Function of SAMHD1 as a Pro-Pathogenic Factor in HIV Infection

Gilad Doitsh; Nicole Galloway; Xin Geng; Isa Monus Arias; Zhiyuan Yang; Warner C. Greene

The J. David Gladstone Institute, University of California San Francisco, San Francisco, CA, US

Background: Depletion of CD4 T cells and development of chronic inflammation are signature processes in HIV pathogenesis that propel disease progression. Due to endogenous SAMHD1 restriction activity in quiescent lymphoid CD4 T cells, the viral chain elongation phase of reverse transcription is attenuated, giving rise to incomplete cytosolic DNA transcripts. CD4 T-cell death is triggered after sensing of these cytosolic DNA intermediates by interferon gamma Inducible protein 16 (**IFI16**). Death occurs following caspase-1 activation in inflammasomes and the induction of **pyroptosis**, a highly inflammatory form of programmed cell death. These findings mechanistically connect CD4 T-cell death and chronic inflammation––the two signature pathogenic processes of active HIV infection.

Methods: Human lymphoid aggregated cultures (HLACs) prepared using tonsil and spleen, and lymph node biopsies from consenting HIV-infected volunteers were used.

Results: We now show that SAMHD1 restriction activity influences how CD4 T cells die. Degradation of SAMHD1 by Vpx encoded by HIV-2 thwarts abortive infection in resting, non-permissive lymphoid CD4 T cells redirecting the cell death pathway away from caspase-1-mediated pyroptotic pathway (inflammatory) toward caspase-3-mediated apoptotic pathway (noninflammatory). SAMHD1 effectively suppresses caspase-1 activation and pyroptosis when infection occurs with cell-free virions. However, in the context of cell-to-cell transmission, which is 100-1,000-fold more efficient, SAMHD1 restriction is only partially effective resulting in the accumulation cytoplasmic viral DNA. This DNA is sensed by IFI16 resulting in caspase-1 activation and triggering of the pyroptotic death pathway. The action of other cellular factors like TREX1 and SLX4 (single and double strand DNA nucleases) may require further increase in the levels the cytosolic DNA needed to trigger pyroptosis.

Conclusions: 1. The Vpx protein thwarts inflammatory pyroptosis following HIV-2 infection by degrading SAMHD1 thereby avoiding abortive infection and sensing of cytosolic viral DNA.

2. SAMHD1 is a bifunctional host factor capably restricting infection of resting CD4 T cells by cell-free HIV virions but functioning as a pro-pathogenic factor when resting CD4 T cells are infected by HIV-1 by the cell-to-cell route.

191 Characterization of the Activity of an Innate Immunity Protein, the Apolipoprotein L6

Nitisha Pyndiah[1]; Angela Ciuffi[1]; Amalio Telenti[2]

[1]*Institute of Microbiology, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland;* [2]*J Craig Venter Institute, San Diego, CA, US*

Background: Host restriction factors are proteins hampering virus replication, and share common features including positive selection, viral counteraction, interferon-inducible expression and differential expression among HIV+ patients. APOL6 was identified in a screen aiming at identifying novel HIV-1 candidate host restriction factors. Another member of the APOL family, APOL1, has been previously described for its protective role against the parasite *Trypanosoma brucei* and more recently as a new HIV restriction factor (Taylor *et al.*, 2013). The aim of the study was to characterize the activity of APOL6.

Methods: We evaluated the ability of APOL6 primate orthologues, chimeras and mutants to inhibit the GFP expression from an HIV-1 based genomic vector in co-transfection experiments. We also assessed the impact of APOL6 on transduction of reporter viruses. Analysis was carried out using flow cytometry

Results: APOL6-mediated restriction was validated in a co-transfection assay with an HIV-1 LTR-EF1-GFP, showing up to 10-fold reduced GFP expression in APOL6-expressing cells compared to control cells. Species-specific restriction of APOL6 primate orthologs co-transfected with HIV-1 LTR-EF1-GFP revealed a higher GFP inhibition mediated by hominids and new world monkey APOL6 compared to old world monkeys APOL6. A similar APOL6-mediated inhibition was observed when APOL6 was co-transfected with alternate GFP expression vectors. In contrast, APOL6 was not able to restrict HIV-based vector transduction nor adenovirus or LCMV. Furthermore, APOL1 and APOL3 constructs were also tested in co-transfection and transduction experiments and followed the same tendency as APOL6. Through co-transfection analyses using human and rhesus APOL6, respectively displaying high and low inhibition ability, we identified a specific APOL6 domain and residue mediating APOL6 effects.

Conclusions: All together, these data suggest that APOL6-mediated activity is not virus-specific, but rather displayed a broad action against various promoter constructs. This points out to a specific APOL6 mechanism, potentially acting at the level of nucleic acid (DNA or RNA) sensing and/or degradation. APOL6 domain and residue responsible for the activity was identified. The mechanism used by APOL6 is very likely to be shared by other members of the family. We are currently identifying APOL6 cellular interactants by Mass spectrometry to elucidate the mechanism of APOL6-mediated restriction.

531 Pharmacokinetic Interactions Between Antidiabetics and Efavirenz Using PBPK Modeling

Catia Marzolini[1]; Rajith Rajoli[2]; Luigia Elzi[1]; Manuel Battegay[1]; David Back[2]; Marco Siccardi[2]

[1]*University Hospital Basel, Basel, Switzerland;* [2]*Institute of Translational Medicine, University of Liverpool, Liverpool, United Kingdom*

Background: Diabetes has emerged as an important co-morbidity in the aging HIV population. The management of diabetes is complicated by the issue of drug-drug interactions (DDI) between antidiabetics and antiretroviral drugs and the lack of clinical data on how to manage these DDI. The antidiabetics pioglitazone (PIO) and repaglinide (REP) are metabolized by CYP2C8 and CYP3A4 and therefore are subject to DDI with efavirenz (EFV), an inducer of CYP3A4 and inhibitor of CYP2C8. The objective of this study was to simulate the pharmacokinetic (PK) interaction between PIO or REP and EFV using physiologically based pharmacokinetic (PBPK) modeling.

Methods: *In vitro* data describing the physicochemical properties, absorption, distribution, metabolism and elimination of PIO, REP and EFV, as well as the CYP induction and inhibition potential of EFV were obtained from published literature. The experimental data were integrated in a PBPK model developed using Simbiology (Matlab, R2013b),

representing molecular, physiological and anatomical processes defining PK. PIO, REP and EFV plasma profiles were simulated in 50 virtual individuals receiving either PIO 15 mg once daily (QD) or REP 2 mg thrice daily (TID) with or without EFV 600 mg QD for 14 days. Dose adjustments of PIO and REP were simulated to overcome the DDI with EFV.

Results: Simulated PK parameters were in agreement with observed clinical data. Simulated versus observed mean AUC and Cmax (± SD) were: 3699 (1413) vs 5020 (1070) ng.h/ml and 535 (80) vs 597 (115) ng/ml for PIO; 50 (16) vs 69 (78) ng.h/ml and 21 (5) vs 48 (32) ng/ml for REP; 92931 (44533) vs 58089 (23046) ng.h/ml and 6158 (1855) vs 4072 (1168) ng/ml for EFV. The geometric mean ratios with 90% confidence interval (GMR, 90% CI) of PIO or REP with and without EFV are presented in the table. An increase in PIO and REP dosage to 22.5 mg QD and 4 mg TID, respectively, was predicted to be sufficient to overcome EFV induction.

Drug	PK parameter	GMR	90% CI
Pioglitazone	AUC	0.53	0.46-0.60
	Cmax	0.77	0.73-0.80
Repaglinide	AUC	0.47	0.42-0.52
	Cmax	0.50	0.45-0.56

Conclusions: The prediction of DDI for drugs whose metabolism is concurrently induced and inhibited can be complex. The developed model, integrating both concurrent effects on CYPs and temporal changes in drug concentrations, shows that EFV has mainly an inducing effect on PIO and REP metabolism. PBPK modeling represents a useful tool to predict complex DDI as often encountered in multimorbid elderly HIV-infected patients and to support the design of prospective clinical trials.

532 In Silico Simulation of Interaction Between Rifampicin and Boosted Darunavir

Marco Siccardi; Owain Roberts; Rajith Rajoli; Laura Dickinson; Saye Khoo; Andrew Owen; David Back

University of Liverpool, Liverpool, United Kingdom

Background: The optimization of antiretroviral regimens in HIV-infected patients co-administered with anti-TB drugs is challenging since rifampicin (RIF), a principal element of the anti-TB therapy, is a strong inducer of key metabolic enzymes. Physiologically-based pharmacokinetic (PBPK) modelling represents an innovative approach to simulate clinical scenarios in the absence of clinical data, by integrating *in vitro* data in mathematical models. The aim of this research was to develop a PBPK model for the co-administration of ritonavir-boosted darunavir (DRV/r) and RIF and predict optimal dosing strategies to overcome the drug-drug interaction (DDI).

Methods: *In vitro* data describing physicochemical properties, absorption, distribution, metabolism and elimination (ADME) of DRV, ritonavir (RTV) and RIF, as well as the inhibition and induction potential of RTV and RIF were determined experimentally or obtained from the literature. A PBPK model was developed integrating experimental *in vitro* data in algorithms representing molecular, physiological and anatomical processes defining ADME. The PK of DRV/r and RIF was simulated in 100 virtual individuals. The impact of RIF (600mg *qd*) on DRV/r was determined and DRV and RTV *qd* and *bid* dose adjustments were simulated.

Results: Simulated DRV/r pharmacokinetic parameters were (mean ± SD) C_{trough} (2.02 ± 1.17 μg/ml), C_{max} (8.23 ± 1.73 μg/ml) and AUC (115.6 ± 32.9 μg/mL.h), which is in agreement with observed PK data for DRV/r 800/100 mg qd in HIV-infected patients: C_{trough} (2.11 ± 1.22 μg/ml), C_{max} (6.75 ± 1.68 μg/ml) and AUC (75.62 ± 26.44 μg/mL.h). The simulated effect of RIF on DRV exposure resulted in a decrement of 57.7% for AUC, 79.5% for C_{trough} and 34.6% for C_{max}. The effect of RIF was overcome by increasing the DRV/ r dose to 1600/200 mg *qd* or 800/100 mg *bid* (Table 1).

Table 1 Ritonavir-Boosted DRV dose adjustments (+RIF) and simulated effect on (mean ± SD) AUC_{24hr} compared to reference dosing (800/100 *qd* - RIF)

qd regimen + RIF	% of AUC_{24hr} compared to reference dosing (800/100 *qd* - RIF)	*bid* regimen + RIF	% of AUC_{24hr} compared to reference dosing (800/100 *qd* - RIF)
800/100	42 ± 18	600/100	89 ± 32
800/150	51 ± 21	600/150	93 ± 33
800/200	58 ± 26	600/200	98 ± 35
1200/100	66 ± 29	**800/100**	**118 ± 43**
1200/150	77 ± 30	**800/150**	**127 ± 44**
1200/200	83 ± 31	**800/200**	**142 ± 58**
1600/100	89 ± 43	**1200/100**	**171 ± 80**
1600/150	99 ± 53	**1200/150**	**186 ± 93**
1600/200	**111 ± 54**	**1200/200**	**197 ± 101**

Conclusions: The developed PBPK model predicted the in vivo pharmacokinetics of DRV/r and the interaction with RIF. Based on these findings, a DRV/r regimen of 1600/200 mg *qd* or 800/100 mg *bid* could mitigate the effect of RIF on DRV/r PK. Mechanistic evaluation of ADME can inform PBPK models and prediction of interaction between drugs. PBPK may be particularly helpful for the rational design of clinical trials evaluating dose adjustment strategies to overcome DDIs in patients concomitantly receiving antiretrovirals and anti-TB drugs.

533 Pharmacogenetics of Pregnancy-Induced Changes in Efavirenz Pharmacokinetics

Adeniyi Olagunju[1]; Oluseye Bolaji[2]; Alieu Amara[1]; Laura Else[1]; Ogechi Okafor[3]; Ebunoluwa Adejuyigbe[2]; Oyigboja Johnson[4]; David Back[1]; Saye Khoo[1]; Andrew Owen[1]

[1]University of Liverpool, Liverpool, United Kingdom; [2]Obafemi Awolowo University, Ile-Ife, Nigeria; [3]Bishop Murray Medical Centre, Makurdi, Nigeria; [4]Catholic Caritas Foundation of Nigeria, Makurdi, Nigeria

Background: Physiological changes during pregnancy coupled with single nucleotide polymorphisms (SNPs) in drug disposition genes are known to alter the pharmacokinetics (PK) of many drugs. In the present study the magnitude of pregnancy-induced changes in efavirenz (EFV) PK in genetically-defined subgroups was investigated.

Methods: This was an observational study with an enrichment design conducted in two phases. In the preliminary phase, we explored associations between selected *CYP2B6*, *NR1I3*, *CYP2A6*, and *ABCB1* SNPs and mid-dose EFV concentrations in an unselected cohort of HIV positive women during pregnancy and postpartum. In the second phase, patients were stratified according to *CYP2B6* 516G>T (rs3745274). Accordingly, randomly selected patients in each genotype group were invited for the intensive PK phase; samples were collected at 0.5, 1, 2, 4, 8, 12 and 24 hours after an observed evening dose of EFV.

Results: A total of 211 HIV positive women taking EFV-based regimens for prevention of mother-to-child transmission (PMTCT) of HIV during pregnancy (n = 77) or postpartum (n = 134) were recruited. Of the nine SNPs investigated, only *CYP2B6* 516G>T was independently associated with EFV plasma concentrations during both pregnancy and postpartum and was used to pre-select patients for the intensive PK phase. A global comparison showed a 42.6% increase in CL/F ($p = 0.02$), 29.8% reduction in AUC_{0-24} ($p = 0.02$) and 50.7% reduction in C_{min} ($p = 0.01$) during pregnancy compared with postpartum. The median (range) C_{min} was 1000 ng/ml (429-5190) and the change in C_{max} was not statistically significant ($p = 0.07$). However, when stratified for *CYP2B6* 516G>T status, EFV CL/F increased by 100% during pregnancy compared with postpartum ($p = 0.001$) in patients with

the *CYP2B6* 516GG genotype. The AUC_{0-24}, C_{max} and C_{min} were reduced by 50.6% ($p = 0.001$), 17.2% ($p = 0.14$) and 61.6% ($p = 0.003$) during pregnancy, with values of 25,900 ng.hr/ml (21,700-32,600), 2640 ng/ml (1260-3490) and 592 ng/ml (429-917), respectively (Table 1).

Table 1. EFV pharmacokinetic parameters* during pregnancy and postpartum based on *CYP2B6<i/> 516G>T genotypes.*

	Clearance/F (L/hr)	AUC_{0-24} (ng.hr/ml)	C_{max} (ng/ml)	C_{min} (ng/ml)
All (CYP2B6 516GG, GT and TT)				
Pregnancy (n = 25)	14.1 (2.96-27.7)	42,600 (21,700-203,000)	3490 (1260-14400)	1000 (429-5190)
Postpartum (n = 19)	9.89 (3.39-20.7)	60,700 (29,000-177,000)	4850 (2050-9760)	2030 (755-6740)

*Values are presented as median (range) and *p<i/> values are for Mann-Whitney U test.*

Conclusions: The clinical relevance of these findings is uncertain, since dose-reduction of EFV in non-pregnant adults was previously not associated with increased risk of virological failure. Nevertheless, the impact of pharmacogenetic variability on mother-to-child transmission of HIV should be further studied.

534 Antiretroviral Drug Transporters and Metabolic Enzymes in Human Testicular Tissue

Billy Huang[1]; Md. Tozammel Hoque[1]; Mohammad-Ali Jenabian[3]; Kishanda Vyboh[2]; Nancy Sheehan[2]; Pierre Brassard[4]; Maud Bélanger[4]; Nicolas Chomont[5]; Jean-Pierre Routy[2]; Reina Bendayan[1]

[1]University of Toronto, Toronto, Canada; [2]McGill University, Montréal, Canada; [3]Université du Québec à Montréal, Montréal, Canada; [4]Metropolitan Centre of Plastic Surgery, Montréal, Canada; [5]Vaccine and Gene Therapy Institute of Florida, Port St Lucie, FL, US

Background: Previous studies have reported that HIV-1 is capable of both acute and persistent infection in the testes. The naturally restrictive environment in the testes due in part to the blood-testes-barrier (BTB), suggests that this barrier could restrict antiretroviral (ARV) penetration into this tissue and contribute to the formation of a viral sanctuary. This study aims to characterize drug transporters and metabolic enzymes expression and localization in the testes of uninfected and HIV-1-infected men receiving antiretroviral therapy (ART) in order to gain further insight on the factors regulating ARV disposition in this organ.

Methods: Testicular tissues were collected from uninfected men (N=8) and HIV-1 infected men on ART (plasma viral load <50 copies/mL for at least 6 months prior to surgery, N=5) who underwent elective orchiectomy for gender reassignment surgery at the Metropolitan Centre of Plastic Surgery in Montreal. We selected four ATP-binding cassette (ABC) transporters, six solute-carrier (SLC) transporters and two cytochrome P450 (CYP450) drug metabolic enzymes to study based on their relevance to ARV disposition, and assessed their gene and protein expression as well as tissue localization.

Results: In testicular tissues, we found that MRP2 and OATP2B1 were highly expressed at the mRNA level, BCRP showed moderate expression, while expression of P-gp, MRP1, OATP1A2, OATP1B1, OAT1, OCT1, CNT1, ENT2, CYP2D6 and CYP3A4 were low. However, we were able to detect robust protein expression for all transporters and metabolic enzymes analysed with the exception of OATP1A2 and OCT1. Overall, gene and protein expression did not differ significantly between the uninfected and ART-treated HIV-1-infected men. Our fluorescence microscopy results also indicate that transporters and metabolic enzymes are not limited to BTB localization but can be found throughout the testicular tissue.

Conclusions: It has been well documented that drug transporters and metabolic enzymes are capable of interacting with many commonly used ARVs, and could significantly affect drug disposition into tissues, especially at key blood-tissue barriers such as the blood-brain barrier. Our data are the first to demonstrate protein expression and localization of key drug transporters and metabolic enzymes in the testes of ART-treated HIV-1 infected men. Their presence suggests the testes are a complex pharmacological compartment that could limit the penetration of several ARVs in this tissue. *(Supported by CIHR and OGS)*

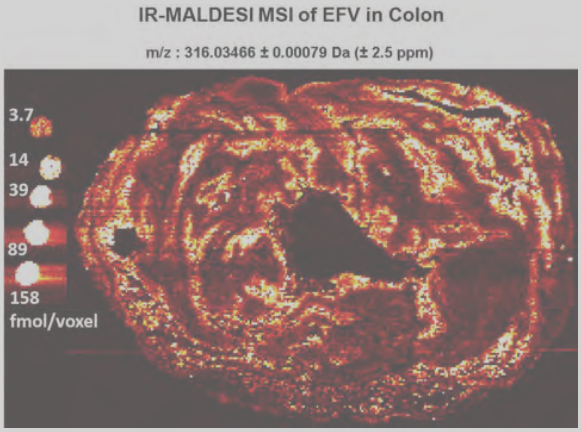
535 Imaging the Spatial Distribution of Efavirenz in Intact HIV Tissue Reservoirs

Elias P. Rosen[1]; Corbin G. Thompson[2]; Mark T. Bokhart[1]; Craig Sykes[2]; Yuri Fedoriw[2]; Paul Luciw[3]; David C. Muddiman[1]; Angela D.M. Kashuba[2]
[1]North Carolina State University, Raleigh, NC, US; [2]University of North Carolina, Chapel Hill, NC, US; [3]University of California Davis, Davis, CA, US

Background: Methods to accurately evaluate ARV biodistribution within tissues are needed to design effective HIV therapy and eradication strategies. Here, we characterize the spatial distribution of efavirenz (EFV) within suspected reservoir tissues of a primate model using a novel approach to mass spectrometry imaging (MSI).

Methods: Reservoir tissues (GALT, lymph nodes, brain, testes) were removed at necropsy from an uninfected rhesus macaque dosed orally to steady-state with EFV. 10 μm cryosections of snap frozen tissue were discretized into 10^{-4} mm^3 voxels, resolving 100 μm features, and analyzed using an infrared matrix-assisted laser desorption electrospray ionization (IR-MALDESI) source coupled to a Thermo Q-Exactive mass spectrometer. Response was calibrated by EFV standards on blank tissue, with a limit of detection of 180 attomole/voxel (57 fg/mm^3 tissue). The results were visualized using custom analysis software. Serial sections of tissue were utilized to validate MSI results by LC-MS, and stained to correlate observed EFV response with tissue morphology (H&E) and immunohistochemistry (CD3 staining).

Results: The presence of EFV was confirmed in all reservoir tissues by MSI, with varying total EFV penetration observed between tissue types. Mapping of EFV response indicated heterogeneous drug exposure. EFV concentration was substantially increased within the mucosa and lamina propria of the colorectal epithelium, specifically corresponding to high density of CD3+ T cells. No such mucosal enhancement was observed in the ileum. Lymph nodes showed focally increased signal in association with some, but not all, primary follicles. Within the brain, grey matter had enhanced EFV exposure relative to white matter. EFV concentration was lowest (167 pg/g tissue) in the basal ganglia, increasing to approximately two-fold in most other tissues (cerebrum, lymph nodes, spleen, testes, and most GALT), and highest in rectal tissue (3.6 fold).



Conclusions: This study is the first to map the biodistribution of an ARV in viral reservoir tissues. Differences in mucosal enhancement in the gut suggest potential differences in biologic transporter activity. Heterogeneous lymph node distribution may indicate insufficient exposure at important sites of viral replication. By differentiating and quantifying drug exposure between cell types within tissue, IR-MALDESI MSI offers a new capability to evaluate drug efficacy and will help inform the selection of optimal interventions to target active viral reservoirs.

724 Cancer in HIV-Infected Children: Record Linkage Study in South Africa

Julia Bohlius[6]; Nicky Maxwell[2]; Brian Eley[3]; Hans Prozesky[4]; Shobna Sawry[1]; Karl-Günter Technau[1]; Alan Davidson[2]; Cristina Stefan[5]; **Matthias Egger**[6]
On behalf of IeDEA Southern Africa
[1]University of the Witwatersrand, Johannesburg, South Africa; [2]University of Cape Town, Cape Town, South Africa; [3]Red Cross War Memorial Children's Hospital, Cape Town, South Africa; [4]University of Stellenbosch and Tygerberg Academic Hospital, Cape Town, South Africa; [5]Stellenbosch University and Tygerberg Hospital, Cape Town, South Africa; [6]University of Bern, Bern, Switzerland

Background: The incidence of AIDS- and non AIDS-defining cancers in HIV-infected children and the impact of ART has not been evaluated in sub-Saharan Africa. We examined the incidence of cancer in HIV-infected children enrolled in antiretroviral therapy (ART) programmes in South Africa, using record linkage techniques.

Methods: We linked records of patients aged ≤16 years from five ART programmes (Harriet Shezi and Rahima Moosa in Johannesburg; Khayelitsha, Red Cross and Tygerberg in Cape Town) to the records of the four corresponding paediatric oncology units (Baragwanath and Charlotte Maxeke in Johannesburg; Red Cross and Tygerberg in Cape Town). Records were linked based on folder numbers, names, birth date and sex. Missing CD4 cell counts and percentages were multiply imputed. We calculated incidence rates and hazard ratios (HR) from Cox regression models including ART, sex, age, and immunodeficiency.

Results: Data of 11,707 HIV-infected children (29,348 person-years [pys]) were included in the analysis. Median age at enrolment was 6 years in children developing and 2.5 years in children not developing cancer. We identified 24 incident cancer cases, for an incidence rate of 82/100,000 pys (95% CI 55-122). Kaposi Sarcoma and Non Hodgkin Lymphoma were the most frequent cancers with incidence rates of 34 and 31/100,000 pys, respectively. There were few non AIDS-defining malignancies. In multivariate analysis, children on ART had a lower risk of developing cancer compared to children not on ART. The risk of developing cancer increased with age and more advanced immunodeficiency (Table). In children with cancer, one year survival was 73% (95% CI 61-82%).

Risk of developing cancer among HIV-infected children in South Africa

		Univariable analyses	Multivariable analyses
		HR (95% CI)	HR (95% CI)
ART	Not on ART	1	1
	On ART	0.43 (0.15-1.22)	0.28 (0.09-0.85)
Gender	Male	1	1
	Female	0.74 (0.33-1.67)	0.71 (0.31-1.61)
Age	< 3 years	1	1
	3 to 5	2.99 (0.66 - 13.61)	2.91 (0.64 - 13.25)
	5 to 10	5.38 (1.64 - 17.65)	5.59 (1.71 - 18.35)
	> 10 years	8.30 (2.21 - 31.22)	8.69 (2.30 - 32.80)
Immunodeficiency	None/mild	1	1
	Advanced/severe	1.87 (0.40 - 8.72)	3.69 (1.11 - 12.29)

HR: hazard ratio, ART: antiretroviral therapy; CI: confidence interval

Conclusions: ART reduces the risk of developing cancer in HIV-infected children in South Africa. Early linkage to care and early start of ART may help to further reduce the burden of cancer in these children.

725 High Cancer Risk Among the HIV-Infected Elderly in the United States

Elizabeth L. Yanik; Hormuzd A. Katki; Eric A. Engels
National Cancer Institute (NCI), Rockville, MD, US

Background: HIV-infected people have higher risk of many cancers compared to HIV-uninfected people, but it is unclear if the magnitude of this elevated risk is consistent across age groups. As the proportion of HIV-infected people over age 65 is increasing over time and the elderly population is known to have high cancer risk, it is important to understand the relationship between HIV and cancer in this age group.

Methods: We conducted a case-cohort study that included a 5% sample of Medicare enrollees and all cancer cases ≥65 years of age identified through the Surveillance, Epidemiology, and End Results cancer registries. Non-melanoma skin cancers were not captured. HIV infection was defined through Medicare diagnosis claims. Weighted Cox regression was used to estimate associations between HIV and cancer incidence adjusting for age, race, sex, and calendar year. The absolute risk of cancer over time was calculated accounting for the competing risk of death.

Results: Among 469,954 people in the 5% Medicare sample, 0.08% had an HIV diagnosis. In total, 835,450 cancer cases were identified in cancer registries. Among HIV-infected people, lung and prostate cancers were most common (N=111 each), followed by non-Hodgkin lymphoma (NHL) (N=57). HIV was strongly associated with incidence of Kaposi sarcoma, anal cancer and Hodgkin lymphoma (hazard ratios of 104, 30, and 12, respectively, Table 1). HIV was also associated with incidence of liver cancer, NHL, and lung cancer, but elevations in risk were lower (hazard ratios of 5, 3 and 2, respectively). Among NHL subtypes, HIV was associated with diffuse large B-cell lymphoma and Burkitt lymphoma, but no association was found with other specified NHL subtypes (which comprised 60% of cases in uninfected people). HIV was associated with lower prostate cancer incidence. Over a 1-year period, 2.5% of the HIV-infected elderly were diagnosed with cancer; by 5 years, this proportion increased to 10.2%.

Table 1: Cancer incidence among HIV-infected and HIV-uninfected individuals over the age of 65

	Incidence Rate*(N)		Hazard Ratio (95%CI)	
Cancer Type	HIV+	HIV-	Unadjusted	Adjusted†
Kaposi sarcoma	63.5 (12)	0.9 (398)	68.81 (38.14-124.15)	104.49 (56.66-192.69)
Non-Hodgkin lymphoma	304.0 (57)	113.2 (49,918)	2.63 (1.97-3.51)	3.48 (2.59-4.67)
Diffuse large B-cell lymphoma	139.0 (26)	30.1 (13,235)	4.53 (3.02-6.80)	6.24 (4.14-9.41)
Burkitt lymphoma	16.1 (3)	0.7 (304)	22.73 (7.24-71.37)	25.15 (7.99-79.14)
Other Specified	75.0 (14)	68.3 (30,071)	1.07 (0.62-1.83)	1.36 (0.79-2.34)
Unspecified	75.0 (14)	14.4 (6,308)	5.10 (2.97-8.76)	7.61 (4.41-13.12)
Hodgkin lymphoma	42.3 (8)	4.0 (1,752)	10.50 (5.18-21.29)	11.50 (5.65-23.42)
Anus	141.9 (27)	5.0 (2,212)	27.68 (18.56-41.27)	29.96 (19.98-44.92)
Liver	116.5 (22)	22.2 (9,806)	5.15 (3.33-7.98)	4.86 (3.12-7.56)
Lung	582.0 (111)	336.6 (148,217)	1.69 (1.35-2.12)	1.78 (1.42-2.23)
Colorectum	212.6 (40)	230.0 (101,085)	0.91 (0.65-1.27)	1.08 (0.77-1.51)
Breast‡	325.5 (16)	362.1 (94,257)	0.88 (0.51-1.52)	0.96 (0.56-1.65)
Prostate‡	805.1 (111)	854.2 (148,504)	0.92 (0.73-1.17)	0.78 (0.61-0.99)

*Incidence is per 100,000 person-years.

†Hazard ratios are adjusted for sex, race, age at start of follow-up, and calendar year at start of follow-up.

‡Breast cancer incidence was only assessed among women. Prostate cancer incidence was only assessed among men.

Conclusions: HIV infection in the elderly is associated with higher risk for many cancers identified as HIV-associated in younger populations. The relative elevation in NHL incidence is notably lower, but this reflects the high frequency in elderly adults of NHL subtypes less strongly associated with HIV. Given the increased risk associated with both aging and HIV, the elderly HIV-infected population has a sizeable absolute risk of cancer, highlighting the need for cancer prevention and screening efforts in this group.

726 Smoking Outweighs HIV-Related Risk Factors for Non–AIDS-Defining Cancers

Keri N. Althoff[1]; Stephen J. Gange[1]; Chad Achenbach[2]; Lisa P. Jacobson[1]; Angel M. Mayor[3]; Michael J. Silverberg[4]; Amy Justice[5]; Richard Moore[6]; Yuezhou Jing[1]; Kelly Gebo[6]
On behalf of the North American AIDS Cohort Collaboration on Research and Design

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [2]Northwestern University, Feinberg School of Medicine, Chicago, IL, US; [3]Universidad Central del Caribe, Bayamon, US; [4]Kaiser Permanente Northern California, Oakland, CA, US; [5]Veterans Affairs Connecticut Healthcare System and Yale Schools of Medicine and Public Health, New Haven, CT, US; [6]Johns Hopkins University School of Medicine, Baltimore, MD, US

Background: The increased burden of non-AIDS-defining cancer (NADC) in HIV-infected adults is likely driven by both HIV-related and other cancer risk factors. The objective of this study is to estimate the population attributable fraction (PAF) for smoking and HIV-related risk factors for NADC, interpreted as the proportion of NADC that could be avoided in HIV-infected adults if all participants had the reference group exposure level.

Methods: Adults (≥18 years) participating in one of 16 contributing cohorts to the North American AIDS Cohort Collaboration on Research and Design who were observed for validated NADC diagnosis from January 1, 2000 to December 31, 2009 were included in this analysis. HIV-related risk factors included CD4 count <200 cells/mm^3, HIV RNA ≥200 copies/mL, and clinical AIDS diagnosis. Hepatitis B (HBV) and C (HCV) infections and smoking were also examined. Data on alcohol use, BMI, and HPV infections were not currently available. Risk factors were measured at study entry, with the exception of time-dependent CD4 count and HIV RNA. Cox proportional hazard models with piecewise constant baseline hazard functions were used to estimate adjusted hazard ratios (aHR) and 95% confidence intervals ([,]). The PAFs for the modifiable risk factors of interest were estimated using the methodology described by Laaksonen, *et al*.

Results: Among 39,554 adults who contributed 159,914 person-years, there were 592 incident cancer outcomes distributed as 101 (17%) lung, 96 (16%) anal, 60 (10%) prostate, 54 (9%) Hodgkin, 42 (7%) liver, and 42 (7%) breast cancers. No other cancer type represented more than 5% of the NADC. At baseline, participants who developed NADC were older and had greater proportions with a history of smoking, dyslipidemia, HBV, HCV, and an AIDS diagnosis compared to those without NADC. The PAFs for the variables in the final model can be seen in Figure 1. After excluding lung cancers from the analysis, the PAF for smoking was 39% [23%, 52%].

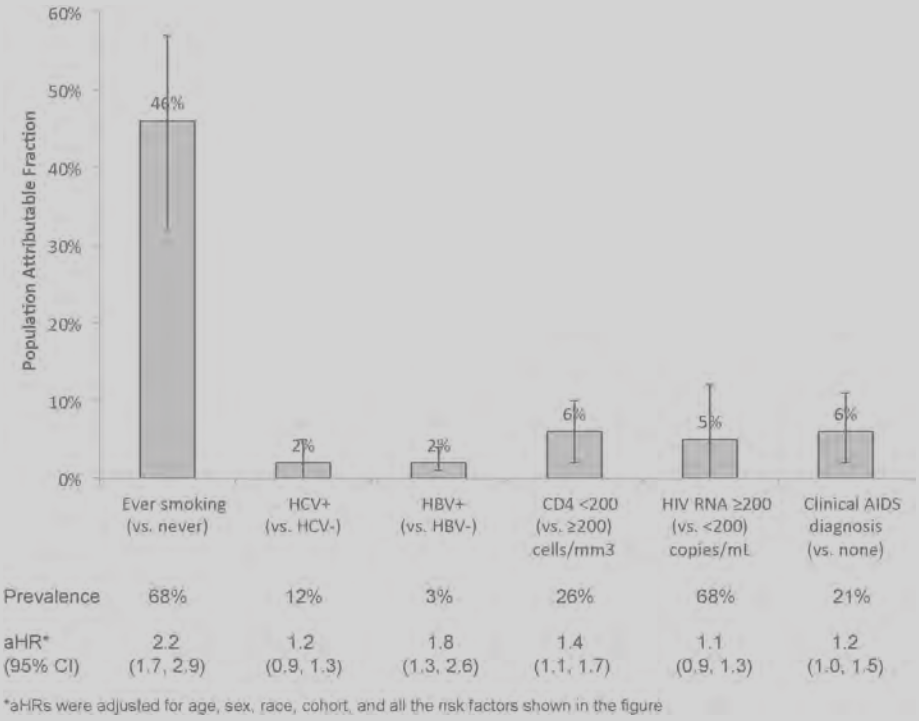


Figure 1: Population attributable fractions and 95% confidence intervals for smoking and HIV-related risk factors for non-AIDS-defining cancers

Conclusions: Programs to prevent smoking initiation among adolescents and young adults at-risk for HIV could prevent up to 46% of NADC in HIV-infected adults. Using ART to preserve immune status, maintain HIV viral suppression, and prevent AIDS-defining illnesses could prevent up to 6% of NADC in HIV-infected adults. In order to reduce the NADC burden in HIV-infected adults, effective interventions to reduce smoking are needed with a continued focus on HIV treatment.

727 High Frequency of Early Lung Cancer Diagnosis With Chest CT in HIV-Infected Smokers

Alain Makinson[1]; Sabrina Eymard-Duvernay[2]; François Raffi[3]; Fabrice Bonnet[4]; Laurence Thirard[5]; Pierre Tattevin[6]; Sophie Abgrall[7]; Jacques Reynes[1]; Vincent Le Moing[1]
on behalf of the ANRS EP48 HIV CHEST Study Team

[1]University Hospital Montpellier, UMI233, Montpellier, France; [2]UMI 233, IRD, University Montpellier 1, Montpellier, France; [3]Nantes University Hospital, Nantes, France; [4]University Hospital Bordeaux, Inserm U897, Bordeaux, France; [5]Tourcoing University Hospital, Tourcoing, France; [6]Pontchaillou University Hospital, Rennes, France; [7]University Hospital Avicennes, Bobigny, France; [8]ANRS, Paris, France

Background: The National Lung Screening Trial has provided compelling evidence of the efficacy of lung cancer screening using chest low-dose computed tomography (LDCT) to reduce lung cancer mortality, but further studies are needed to evaluate LDCT screening in different populations. We sought to study the feasibility and to identify specificities of early lung cancer diagnosis with LDCT in HIV-infected smokers.

Methods: The ANRS EP48 HIV CHEST study is a French, multicentre, prospective study consisting of a one round, millimetric, chest LDCT of HIV-infected subjects ≥ 40 years with a history of cumulative smoking within the last 3 years ≥ 20 pack-years, a CD4 T-lymphocyte nadir cell count < 350/µl, and a last CD4-T cell count > 100 cells/µl. A significant nodule on baseline CT, inducing CT follow up or immediate diagnostic procedures, was defined by a solid or partly solid nodule ≥ 5 mm or a non solid nodule ≥ 8 mm. Follow up and biopsy procedures were suggested in a workup algorithm, with a systematic follow-up of 2 years. Under the hypothesis of a 2.6 increased risk of lung cancer in HIV-infected smokers versus HIV-uninfected counterparts, we estimated lung cancer prevalence to be 3%. Hence, we aimed to enrol 445 patients, and expected 13 diagnosis of lung cancer [95% Confidence Interval, 7-22].

Results: Between March 2011 and June 2012, 442 subjects were enrolled. Median age was 49.8 years, (interquartile range (IQR) 46.3-53.9), 84% were men, median cumulative smoking was 30 pack-years (IQR 25-40), median last CD4 and nadir CD4 cell counts were 574/µl (IQR 408-765) and 168/µl (IQR 75-256) respectively, and 90% had a plasma HIV RNA < 50 copies/ml. A significant nodule was reported in 94 (21%) subjects on baseline CT. Lung cancer (5 staged IA) was diagnosed in 8 subjects (1.81 %), all but one in subjects aged < 55 years (table). There were no serious adverse events due to diagnostic procedures, and 29 subjects were lost to follow up.

Age (yr)	Sex	Lung cancer type	Stage	Smoking (pack-years)	Nadir CD4 count (cells/µl)	Last CD4 value (cells/µl)	Time (wks) between baseline CT and lung cancer diagnosis
45	M	Adenocarcinoma	IA	30	160	637	23
46	F	Adenocarcinoma	IV	52	132	597	76
49	M	Adenocarcinoma	IA	45	321	378	70
50	F	Adenocarcinoma	IV	27	60	590	12
52	M	Adenocarcinoma	IV	35	236	568	66
52	M	Adenocarcinoma	IA	60	214	859	7
54	M	Squamous cell	IA	28	71	345	23
56	M	Adenocarcinoma	IA	34	201	480	7

M : Male; F: Female

Conclusions: Early lung cancer diagnosis and nodule follow up with LDCT are feasible in HIV-infected smokers. Prevalence of lung cancer was within expected range and 5/8 cancers were surgically curable stage IA. The rate of significant nodules on baseline CT was not higher than the ranges published in non HIV-infected screening studies. Lung cancer

screening of subjects between the ages of 55-74 years as recommended in the general population may miss substantial numbers of cancers in HIV-infected smokers with a nadir CD4 cell count < 350/μl.

728 CD4 Measures as Predictors of Lung Cancer Risk and Prognosis in HIV Infection

Keith Sigel[1]; Kristina Crothers[2]; Kirsha Gordon[3]; Sheldon Brown[4]; David Rimland[5]; Maria Rodriguez-Barradas[6]; Cynthia Gibert[7]; Matthew B. Goetz[8]; Roger Bedimo[9]; Robert Dubrow[10]

[1]Icahn School of Medicine at Mount Sinai, New York, NY, US; [2]University of Washington School of Medicine, Seattle, WA, US; [3]VA Connecticut Healthcare System and Yale University Schools of Medicine and Public Health, New Haven, CT, US; [4]James J. Peters VA Medical Center, Bronx, NY, US; [5]Atlanta VA Medical Center, Atlanta, GA, US; [6]Michael E. DeBakey Veterans Affairs Medical Center, Houston, TX, US; [7]Washington DC Veterans Affairs Medical Center, Washington, DC, US; [8]Los Angeles VA Medical Center, Los Angeles, CA, US; [9]Veterans Affairs North Texas Health Care System, Dallas, TX, US; [10]Yale University School of Public Health, New Haven, CT, US

Background: Immunodeficiency may adversely affect both lung cancer risk and outcomes in the setting of HIV infection. Using data from a large HIV cohort, we investigated relationships between 1) recent and cumulative measures of CD4 and CD8 count and lung cancer incidence and 2) CD4 measures and lung cancer prognosis.

Methods: We followed 26,065 HIV+ subjects from the Veterans Aging Cohort Study (VACS) for a minimum of 2 years, during 1999-2010. We linked VACS with the VA Central Cancer Registry to obtain incident, pathologically confirmed lung cancer cases. Our exposures of interest were longitudinal CD4 (<200 cells/mm^3 [c/mm^3], 200-500 c/mm^3 or >500 c/mm^3), CD4/CD8 (<0.4 or ≥0.4) and CD8 (≥850 c/mm^3 or <850 c/mm^3). We used Cox regression models to investigate the effect of time-updated CD4, CD4/CD8 ratio and CD8 measures on lung cancer risk, including values lagged 12 months, and 12- and 24-month simple moving averages. Models were adjusted for age, sex, race/ethnicity, smoking, and history of pneumonia and COPD. We then collected all non-small cell lung cancer cases from the full VACS (HIV+ and HIV- subjects from 1996-2010) and used conditional probability function regression (a competing risks method to account for higher risk of non-lung cancer death in HIV+) to compare lung cancer-specific survival in 3 groups: HIV- (n=679), HIV+ with CD4≥200 c/mm^3 at cancer diagnosis (n=299) and HIV+ with CD4<200 c/mm3 at cancer diagnosis (n=113). These analyses were adjusted for demographics, comorbidity score, cancer stage and histology, cancer diagnosis year, and cancer treatment.

Results: We identified 325 (1.2%) cases of incident lung cancer in our cohort. In adjusted models (Table 1), a 12 month lagged CD4 count <200 c/mm^3 as well as moving averages of both CD4<200 c/mm^3 and CD4 200-500 c/mm^3 were significantly associated with increased lung cancer incidence. In similar adjusted models, 12-month moving averages of CD4/CD8 ratio <0.4 were also significantly associated with increased risk of lung cancer. Among lung cancer cases, lung cancer-specific survival did not differ between either of the HIV+ groups and the HIV- group (p>0.05) after adjustment.

Table 1. Adjusted hazard ratios for lung cancer by CD4, CD4/CD8 ratio, and CD8 exposures.

Analyses	Lung Cancer Incidence	
	Hazard Ratio*	95% CI
CD4 Analyses		
12 Month Lagged Value		
<200 cells/mm^3	1.6	1.2-2.2

*Individual time-updated Cox regression models for risk of lung cancer adjusted for age, sex, race/ethnicity, smoking status, history of pneumonia, and history of COPD

Table 1. Adjusted hazard ratios for lung cancer by CD4, CD4/CD8 ratio, and CD8 exposures.

Conclusions: In our large HIV cohort, we found that several measures of recent and cumulative exposure to immunodeficiency were associated with increased lung cancer risk. CD4 count at time of cancer diagnosis was not associated with cancer-specific survival after accounting for competing risk of non-lung cancer death.

834 Local and Systemic Humoral Responses to Cryptococcal Meningitis in Patients With AIDS

Erin E. Finn[1]; Jordan Janoff[1]; Jeremy Rahkola[1]; David B. Meya[2]; Samuel Okurut[2]; Andrew D. Kambugu[2]; Paul Bohjanen[3]; Kirsten Nielsen[3]; David R. Boulware[3]; Edward N. Janoff[1]

[1]Mucosal and Vaccine Research Colorado, Aurora, CO, US; [2]Makerere University College of Health Sciences, Kampala, Uganda; [3]University of Minnesota, Minneapolis, MN, US

Background: Antibodies may support protection against meningitis caused by *Cryptococcus neoformans* (CM), a prominent cause of disease and death in persons with AIDS, among whom antibody defects are common.

Methods: We measured total and Cryptococcus-specific IgG and IgM antibody levels by ELISA in serum and cerebrospinal fluid (CSF) from 41 antiretroviral therapy naïve adults with AIDS at the time of CM diagnosis in Kampala, Uganda. Cryptococcus-specific antibodies were directed against capsular glucuronoxylomannan (GXM) or unencapsulated organisms. Immune complexes (IC) were dissociated and neutralized with acid treatment and glycine.

Results: The median CD4+ T cell count was 16/μL and log_{10} HIV RNA was 5.33 copies/mL. CSF-analysis showed median protein of 70 mg/dL, WBC of 30/mL [43% had <5 cells], cryptococcal antigen (CrAg) titer of 1:4,000 and cryptococcal colony forming units of log_{10} 5.4/mL. Total IgG in CSF exceeded IgM by over 20 fold (median 127 vs. 5.8 μg/mL). Levels of IgG and IgM specific to GXM were greater than levels specific to unencapsulated organisms. We detected GXM-specific IgG and IgM in CSF of 46% and 24% of subjects, respectively, and in 100% of sera. The antibodies detected in CSF were specific for GXM based on cross-adsorption with heterologous polysaccharides and proteins, but the specificity of IgM exceeded that of IgG. In the CSF, GXM-IgM was produced locally, whereas the GXM-IgG was likely transferred from serum based on the ratios of GXM-specific to total IgM and IgG in CSF and serum. The majority of GXM-IgG but not IgM in the CSF was bound by local capsular GXM as levels increased by 10-fold upon dissociation of IC. IC-bound antibodies had greater avidity than antibodies freely circulating in CSF. Levels of GXM-IgG or -IgM did not correlate with CSF WBC, protein, CrAg titer or mortality (11 of 41 died [26.8%] within 30 days).

Conclusions: Specific antibodies that recognize the predominant capsular polysaccharide of *C. neoformans* (GXM) are present in the CSF of a subset of AIDS patients with CM. GXM-IgM, although present in fewer patients, was higher in concentration, specificity and avidity than GXM-IgG and was more likely produced locally at the site of infection. Enhancing levels of such antibodies may support opsonization of *C. neoformans*, promote cytokine production and cellular immune responses to the organism, and thereby faciliate protection against these common and often fatal infections.

835 Antiretroviral Therapy Alters the CSF Immune Response in Cryptococcal Meningitis

James E. Scriven[1]; Britta Urban[1]; Lisa Graham[2]; Charlotte Schutz[2]; Robert J. Wilkinson[3]; David R. Boulware[4]; David Lalloo[1]; Graeme Meintjes[2]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom; [2]University of Cape Town, Cape Town, South Africa; [3]Imperial College London, London, United Kingdom; [4]University of Minnesota, Minneapolis, MN, US

Background: Cryptococcal meningitis (CM) is an important opportunistic infection in sub-Saharan Africa. Animal models suggest a M2 (alternatively activated) macrophage phenotype and Th2 response are detrimental during infection but studies in humans are limited. To address this we characterized the CSF immune response in HIV-associated CM, examined the effects of ART, and explored the relationship between CSF immune response, fungal burden and mortality.

Methods: A prospective cohort study was conducted in South Africa. Persons with CM were enrolled and followed for 12 weeks. CSF immune response was examined using 11-colour flow cytometry and 17-plex luminex analysis. Fungal burden was measured using quantitative culture. Data were analysed using principal component analysis; p<0.05 with a false discovery rate (q) <0.1 were used to infer statistical significance.

Results: 57 subjects were enrolled: 42 not taking ART, 8 on effective ART and 7 with virological failure on ART. Median CD4 count was 34 cells/μL and median CSF WCC 18/μL. CD8 T cells were the most frequent CSF cell followed by neutrophils, macrophages and CD4 T cells (median 50%, 12%, 6.7% and 6.2% WCC respectively). Compared to individuals not on ART, the CSF of those taking effective ART had significantly increased CD4 T cells, decreased CD8 T cells, increased CD4/CD8 ratio and increased CD206 expression on CD14+ and CD14- macrophages - suggesting M2 phenotype (**table 1**). CD206 expression was inversely correlated with plasma viral load (even in persons not taking ART (r=-0.59, p=0.0001)) but was not associated with fungal burden (r=-0.02, p=0.893). Fungal burden was inversely correlated with CSF GCSF, IL6, CD4, CD8, CD4-CD8- and NK cells (r= -.49, -.41 -.61, -.55, -.49, -.40 respectively; all p <.05 and q<.1). Non-survivors had decreased CSF CD4-CD8- T cells and reduced CSF IFNγ but this was not significant when adjusted for multiple comparisons (p=.021 q=.92; p=.038, q=.97; respectively).

CSF Parameter	Effective ART		No ART		p	q
	Mean (geo)	95% CI	Mean (geo)	95% CI		
CD4 (%WCC)	13.7	7.7-24.8	4.5	3.4-6.1	0.0026	0.040
CD8 (% WCC)	19.1	11.1-32.8	47.5	40.5-55.7	0.0000	0.002
Large T cells (%WCC)	0.10	0.03-0.3	1.05	0.73-1.52	0.0000	0.023
CD4/CD8 ratio	0.72	0.29-1.75	0.08	0.05-0.13	0.0006	0.001
HLA-DR+ (% CSF CD4)	29	19-46	45	40-50	0.0075	0.060
CD206 CD14+M (MFI)	6568	3229-13227	2752	2143-3498	0.0055	0.050
CD206 CD14-M (MFI)	3327	1003-11038	938	702-1253	0.0019	0.023
CD16 CD14-M (MFI)	413	299-571	238	197-286	0.0120	0.073

Table 1. *Immune parameters that differed significantly between subjects taking effective ART and those who were not. Geometric means are displayed; parametric tests were performed on log2 transformed variables. Q values refer to the false discovery rate. "Large T cells" were a secondary population of T cells with increased forward scatter. WCC=white cell count; M=macrophage*

Conclusions: In CM, ART is associated with an increased CSF CD4/CD8 ratio and an increased M2 macrophage phenotype, likely mediated through effects on HIV viral load. In contrast to animal data the M2 phenotype was not associated with increased fungal load or fatal outcome. Instead, fungal burden was negatively correlated with CSF T cells (CD8, CD4 and CD4-CD8-) and concentrations of pro-inflammatory cytokines. This is supportive of the theory that a paucity of CSF inflammation is associated with severe disease in CM.

836 Detrimental Outcomes of Unmasking Cryptococcal Meningitis With Recent ART Initiation

Joshua Rhein[1]; Katherine H. Hullsiek[1]; Nathan C. Bahr[1]; Reuben Kiggundu[3]; Darlisha Williams[3]; Henry W. Nabeta[3]; Abdu Musubire[3]; David B. Meya[3]; David R. Boulware[1]

[1]University of Minnesota, Minneapolis, MN, US; [2]University of Minnesota, Minneapolis, MN, US; [3]Makerere University College of Health Sciences, Kampala, Uganda

Background: Cryptococcal meningitis (CM) remains a major cause of HIV-related mortality in Africa. Increased antiretroviral therapy (ART) availability coupled with a lack of pre-ART cryptococcal antigen screening has led to a greater proportion of patients developing CM after initiating ART. Despite this changing epidemiology, data regarding CM in patients already receiving ART are lacking. We compared the clinical presentation and outcomes in ART-naïve and ART-experienced Ugandans.

Methods: We enrolled a prospective cohort of 165 HIV-infected persons with cryptococcosis in Kampala, Uganda from Aug 2013 to Aug 2014. Subjects were classified by ART status, the timing of ART initiation, and previous CM history. The primary endpoint was 2-week mortality. Statistical comparisons were made with Kruskal-Wallis or Fisher's Exact tests.

Results: 87% (144/165) of subjects presented with their first episode of CM whereas 13% (21/165) had a previous history of CM. Of those with first CM episode, 40% (58/144) were receiving ART at presentation, having initiated ART a median of 110 (IQR, 20-519) days prior to CM diagnosis. Those receiving ART had higher CD4 (median 32 (IQR, 10-73) vs 12 (IQR, 6-39) cells/mcL; *p*=.02) and lower CSF fungal burdens (median 4.0 (IQR, 2.5-4.9) vs 4.8 (IQR, 3.9-5.6) log_{10} CFU/mL CSF; *p*<.001). 55% (32/58) had initiated ART within the last 4 months, and 22% (13/58) initiated ART within the last 14 days. Persons starting ART <4 months prior were more likely to present with altered mental status (44% vs 19% with GCS<15, *p*=.05) despite having lower CSF fungal burdens (median 3.7 (2.3-4.3) vs 4.5 (3.4-5.1) log_{10} CFU/mL; *p*=.04) compared to those initiating ART >4 months prior to

CM diagnosis. CSF WBC did not differ. The 2-week mortality was significantly higher in those on ART for <14 days (54%) compared to those on ART for 15 days to 4 months (16%; p=.05), >4 months (12%; p=.01), or ART-naïve (24%). CM presenting after >4months on ART was an indication of virologic failure.

Conclusions: The occurrence of CM after initiating ART is now common in Africa. Although these patients have higher CD4 counts and lower fungal burdens, outcomes do not appear to be improved. Patients developing CM within 14 days of initiating ART are at a higher risk of death. Immune recovery in the setting of a CNS infection is detrimental, and management of this population requires future study. Implementing pre-ART cryptococcal antigen screening would decrease CM occurring early after ART initiation.

837 Impact of ART on Mortality in Cryptococcal Meningitis Patients: High-Income Settings

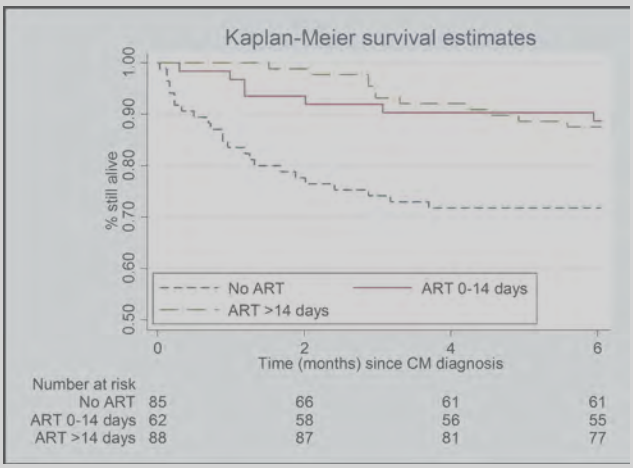
Suzanne M. Ingle[1]; Jose M. Miro[2]; Hansjakob Furrer[4]; Amy Justice[5]; Michael S. Saag[6]; Christian Manzardo[2]; Anna Esteve[7]; Lauren E. Cain[3]; Jonathan A. Sterne[1]; Margaret T. May[1]

[1]University of Bristol, Bristol, United Kingdom; [2]Hospital Clínic–L'Institut D'Investigacions Biomèdiques August Pi i Sunyer, University of Barcelona, Barcelona, Spain; [3]Harvard School of Public Health, Boston, MA, US; [4]Bern University Hospital and University of Bern, Bern, Switzerland; [5]Yale University School of Medicine, VA Connecticut Healthcare System, New Haven, CT, US; [6]University of Alabama at Birmingham, Birmingham, AL, US; [7]Centre d'Estudis Epidemiològics Sobre ITS/VIH/SIDA de Catalunya, Barcelona, Spain

Background: Randomised trials (RCTs) from low-income countries have shown that early ART among antiretroviral-naïve HIV-1–infected patients presenting with cryptococcal meningitis (CM) is associated with higher mortality than delayed ART. There is limited information on the impact of timing of ART on short-term mortality in patients with CM cared for in high-income settings.

Methods: Data on ART-naive patients diagnosed with CM between 1998 and 2009 were combined from cohorts contributing to the COHERE, NA-ACCORD and CNICS collaborations. Follow-up time was calculated from date of CM diagnosis to the first of death, last follow-up or 6 months post-diagnosis. We mimicked an RCT comparing regime A ("start ART within 14 days of CM diagnosis") with regime B ("defer ART until 14 -56 days after CM diagnosis"). Marginal structural models were used to compare the effects of these regimes on all-cause mortality. Models were adjusted for gender, age, mode of transmission, CD4, viral load (VL), AIDS (other than CM), year of diagnosis and whether data were European/North American.

Results: Of 235 patients (84% male) from 28 cohorts across Europe and N. America with full covariate data, 42 (18.0%) died within 6 months. Median age at CM diagnosis was 38 years (IQR 34-44). Of 150 patients (64%) who started ART, 18 (12%) died within 6 months. 7/62 (11%) patients died among those who started ART within 2 weeks of CM diagnosis, compared with 11/88 (12%) among those who started ART after 2 weeks. The graph shows crude survival over time, according to when the patient started ART. In data mimicking an RCT, there were 15 deaths (33.3 years follow-up) in regime A and 26 deaths (47.8 years) in regime B. The crude and adjusted hazard ratios comparing deferred with early treatment were 1.29 (95% CI 0.68-2.43) and 1.30 (0.66-2.55).



Kaplan-Meier survival estimates according to time of starting ART

Conclusions: We found little evidence that early ART was associated with higher mortality after CM than deferred ART, although confidence intervals were wide. Although we adjusted for potential confounding factors, confounding and selection bias may not be fully adjusted for; we aim to address this limitation by ascertaining additional information on treatment of CM after diagnosis. Mortality among patients cared for in high income settings was clearly lower than reported in the RCTs conducted in low-income countries.

838 Adjunctive Sertraline for the Treatment of HIV-Associated Cryptococcal Meningitis

Joshua Rhein[1]; Katherine H. Hullsiek[1]; Bozena Morawski[1]; Kyle Smith[1]; Ali Al-Hadab[1]; Abdu Musubire[2]; Darlisha Williams[2]; Kristen Nielsen[1]; David B. Meya[2]; David R. Boulware[1]

[1]University of Minnesota, Minneapolis, MN, US; [2]Makerere University College of Health Sciences, Kampala, Uganda

Background: Mortality from HIV-associated cryptococcal meningitis (CM) remains unacceptably high. Identifying new effective antifungals is of paramount importance. We evaluated the efficacy of adjunctive sertraline, previously demonstrated to be active against *Cryptococcus neoformans* both *in vitro* and in murine models.

Methods: 144 HIV-infected persons with first episode of CM were prospectively enrolled in a phase IIb, open-label clinical trial in Kampala, Uganda between Aug 2013-2014. Sertraline at doses of 100-400 mg/day was added to standard therapy (amphotericin + fluconazole 800mg/day). Early fungicidal activity (EFA) was measured as the rate of cryptococcal clearance in serial quantitative CSF cultures and calculated by mixed effect model for all participants with at least 2 CSF cultures (N=122). Sertraline concentrations in plasma were measured using high performance chromatography–mass spectrometry in 77 subjects to evaluate how rapidly sertraline achieves steady state. *In vitro* susceptibility was assessed on a subset of *C. neoformans* isolates (N=95) to determine target 90% minimum inhibitory concentration (MIC90).

Results: Those receiving any dose of sertraline had 28% faster rate of clearance compared with recent historical controls (Table): EFA -0.39 vs. -0.30 for those with vs. without sertraline (p=0.03). Sertraline reached steady state in plasma by day 7, with a median level of 215 (IQR, 126-305) ng/mL at 200mg/day and 400 (IQR, 281-556) ng/mL at 400mg/day. Plasma levels were 68% of steady state levels by day 3. The projected steady state brain tissue concentration at 200mg/day was a median of 3.5 (IQR, 2.1-5.0) mcg/mL and at 400mg/day was 6.6 (4.6-9.2) mcg/mL. Among *Cryptococcus* isolates, the MIC90 was ≤1 mcg/mL for 9.5%, ≤2 mcg/mL for 30.5%, ≤4 mcg/mL for 84%, and ≤8 mcg/mL for 99% of isolates. *In vitro* synergy studies (n=9) found a median 2-fold reduction in the MIC90 with a combination of sertraline and fluconazole. For sertraline at doses 200-400mg/day, the incidence of paradoxical IRIS or relapse through 12 weeks was 1%.

Table: Early Fungicidal Activity of the Rate of CSF Clearance in Cryptococcal Meningitis

Anti-Fungal Induction Regimen	N	EFA[1] (95% CI) log_{10} CFU/mL
Standard therapy [2] + 100 mg/day sertraline	13	-0.37 (-0.41, -0.24)
Standard therapy [2] + 200 mg/day sertraline	40	-0.40 (-0.48, -0.31)
Standard therapy [2] + 300 mg/day sertraline	38	-0.39 (-0.47, -0.32)
Standard therapy [2] + 400 mg/day sertraline	31	-0.37 (-0.47, -0.29)
Standard therapy + all sertraline regimens	122	-0.39 (-0.43, -0.34)
Standard therapy without sertraline [2,3]	189	-0.30 (-0.32, -0.28)

[1] EFA (Early Fungicidal Activity) estimated with longitudinal mixed models. Values are population means with 95% confidence intervals (95% CI).

[2] Standard therapy: Amphotericin B deoxycholate (0.7-1.0mg/kg/day)+ fluconazole 800mg/day.

[3] Historical controls, enrolled from November 2010 through July 2013.

Conclusions: Sertraline provides fungicidal activity against *C. neoformans* with improvements in CSF clearance rates and appears to reach therapeutic levels *in vivo*. This widely available off-patent oral medication ($0.05 per 100mg tablet) provides a promising adjunct for CM treatment when added to standard antifungal therapy. This pilot justifies a larger randomized trial to elucidate whether sertraline has a survival benefit for the treatment of CM.

1060 Trends in Sexual Behaviors Among Men Who Have Sex With Men in the United States, the Role of Antiretroviral Therapy and Seroadaptive Strategies

Gabriela Paz-Bailey[1]; Maria Mendoza[1]; Binh Le[1]; Charles E. Rose[1]; Teresa Finlayson[1]; Cyprian Wejnert[1]; Henry F. Raymond[2]; Joseph Prejean[1]

[1]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US; [2]San Francisco Department of Public Health, San Francisco, CA, US

Background: CDC data from the National HIV Behavioral Surveillance System (NHBS) suggest that condom use has decreased among men who have sex with men (MSM). The reasons for this decrease are not known but may reflect the adoption of risk-reduction strategies other than consistent condom use, such as engaging in unprotected sex only with partners perceived to have the same HIV status as one's own (sero-adaptive behaviors). We used data among MSM participating in NHBS to evaluate changes from 2005 to 2011 in condomless anal sex at last sex.

Methods: MSM were recruited through venue-based sampling in 2005, 2008 and 2011 in up to 21 U.S. cities. Among men reporting ≥1 male partner and self-reporting as HIV-positive or HIV-negative, we evaluated changes in condomless anal sex at last sex with a partner reported to have 1) HIV concordant status (proxy for sero-adaptive behavior), or 2) HIV-discordant or unknown status, by participant's reported HIV status and antiretroviral therapy (ART) use (HIV-positive only). We used GEE modeling with a robust variance estimation, and assumed a Poisson distribution to explore whether temporal changes in the outcomes varied by selected characteristics.

Results: In adjusted analyses among 23,125 HIV-negative MSM, concordant condomless sex at last anal sex increased significantly (20%, 22% and 24%, in 2005, 2008 and 2011, respectively, p<0.001) as well as discordant/unknown condomless sex (7%, 10%, 11%, respectively, p<0.001). Among 3,785 HIV-positive MSM, there were no significant changes in concordant (19%, 21% and 26%, p=0.14) or discordant/unknown condomless sex (14%, 16%, and 14%, p=0.11). Concordant condomless sex increased among MSM on ART (18%, 22%, and 26%, p<0.001) but not among MSM not on ART (21%, 20% and 27%, p=0.11). There were no significant changes in discordant/unknown condomless sex by ART use.

Conclusions: There were modest increases in condomless sex at last sex both with partners of concordant and discordant/unknown HIV status among HIV-negative MSM, and only with a partner of concordant status among HIV-positive MSM on ART. These data suggest that the increases in condomless sex among MSM are in part due to the adoption of sero-adaptive behaviors but that discordant condomless sex is also increasing among HIV-negative MSM. HIV-negative MSM who engage in condomless sex would benefit from having access to risk-reduction interventions, including pre-exposure prophylaxis.

1061 Changes in Condomless Sex and Serosorting Among MSM After HIV Diagnosis

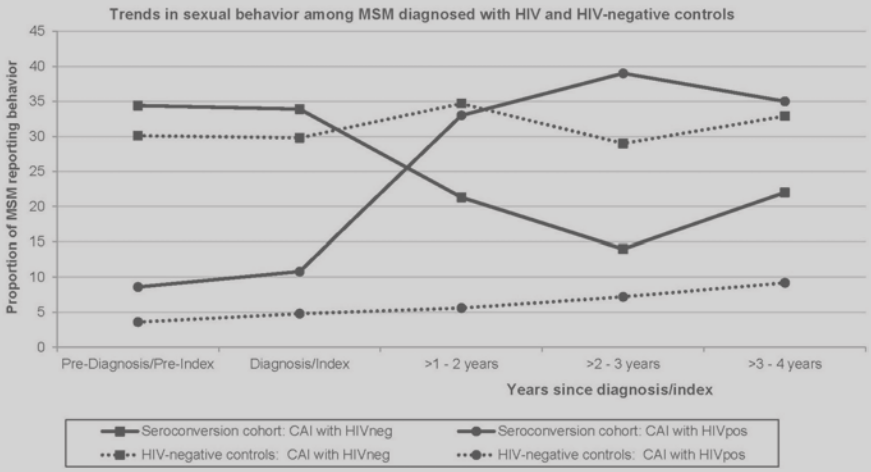
Christine M. Khosropour[2]; Julia C. Dombrowski[2]; David A. Katz[2]; Matthew R. Golden[2]

[1]University of Washington, Seattle, WA, US; [2]University of Washington, Seattle, WA, US

Background: Among men who have sex with men (MSM) diagnosed with HIV, high-risk sexual behaviors may decline in the year after diagnosis, but changes in serosorting post-diagnosis are not well defined. Few studies have assessed changes in these behaviors both pre-diagnosis and for several years after.

Methods: We created a retrospective cohort (seroconversion cohort) of MSM attending an STD clinic in Seattle, WA who tested HIV positive between 2002-2013 and had a negative HIV test ≤2 years prior to diagnosis (pre-diagnosis visit). Potential controls were MSM who never tested HIV-positive and had a negative test ≤2 years prior to a randomly selected index visit. We randomly selected 1,000 controls frequency-matched to the seroconversion cohort based on HIV diagnosis year/index date. Sexual behavior data in the 12 months prior to each visit were collected by clinicians using standardized forms or a computer self-interview as part of routine clinical care. We examined condomless anal intercourse (CAI) with HIV-negative and -positive partners at 5 time points: before diagnosis/index, at diagnosis/index, and each year up to 3 visits after diagnosis/index. We used McNemar's chi-square to compare behaviors reported at the 2 visits before/at diagnosis vs. the 3 visits after diagnosis and used linear regression to examine trends over time.

Results: There were 655 (2.5%) new HIV diagnoses at 26,144 clinic visits where MSM tested for HIV; 186 (28%) men with a new diagnosis tested negative ≤2 years before diagnosis and were included in the seroconversion cohort. The 1,000 persistently HIV-negative controls were selected from 3,083 eligible MSM. In the seroconversion cohort, the percent reporting CAI with HIV-negative partners declined after diagnosis (34% vs 19%, P=.003) while the percent reporting CAI with HIV-positive partners increased (10% vs 35%, P<.001; Figure). Thus, the proportion who serosorted (i.e. reported only HIV concordant CAI) did not change before or after diagnosis (34% vs 35%, P=.85) and remained stable in the years after diagnosis (P-value for trend post-diagnosis=.79). Among HIV-negative controls, serosorting and CAI with HIV-positive partners remained relatively constant.



Conclusions: Among MSM in our clinic, those diagnosed with HIV modified their sexual behaviors post-diagnosis based on partner HIV status and this change was sustained several years after diagnosis. These findings suggest that, among MSM, changes in sexual behavior following HIV diagnosis are large and durable.

1062 Serosorting and Sexual Risk Behavior Influenced by Perceived HIV Serostatus Among MSM

Kathleen A. Brady; Jennifer Shinefeld; Catherine Mezzacappa

Philadelphia Department of Public Health, Philadelphia, PA, US

Background: According to the CDC, unknown HIV serostatus and unprotected anal sex among men who have sex with men (MSM) contribute to high levels of new infections in this population. This study used data from the National HIV Behavioral Surveillance System (NHBS) to analyze the relationship between perceived HIV serostatus and high-risk sexual behaviors among MSM.

Methods: NHBS is conducted annually in 20 metropolitan areas using a standardized survey and free HIV testing to analyze trends in HIV risk behaviors and prevalence among high risk groups including MSM. HIV testing included a rapid test at time of interview and a confirmatory test. We combined data from the 2008 and 2011 MSM cycles in Philadelphia and performed bivariate analyses of sexual risk behaviors at last sexual encounter across perceived HIV serostatus. Perceived HIV serostatus was defined as 'known negative' for a man who had a negative HIV test in the past year, 'known positive' for a man who had ever tested positive for HIV, and 'unknown' for a man who had not had an HIV test in the past year nor previously tested positive. Serosorting is the practice of choosing a partner known to be of the same HIV serostatus in order to reduce the risk of acquiring or transmitting HIV.

Results: Of 1194 respondents, 31.3% were known negative, 5.5% known positive, and 63.2% unknown perceived serostatus. Testing revealed that 3.0% of known negative and 4.4% of unknown perceived serostatus were HIV positive. There were no differences in frequency of insertive anal sex at last encounter across perceived serostatus. Known negative men were less likely to use a condom during receptive anal intercourse (p=0.006). Approximately two-thirds of all respondents knew the HIV status of their most recent partner. Among those who knew their partner's HIV status, serosorting was extremely prevalent: 73.9% of known positive men had sex with an HIV positive partner, compared to 5.6% of unknown, and 4.4% of known negative men, (p<0.0001).

Table 1. Behaviors at last sexual encounter by perceived HIV status

	Known Negative N=373	Known Positive N=66	Unknown N=755	p-value
Actual HIV status				
Negative	97.0% (356/367)	0	95.6% (673/704)	
Positive	3.0% (11/367)	100% (66)	4.4% (31/704)	
Type of partner				
Main	34.3% (71/207)	36.1% (13/36)	37.0% (114/308)	0.37
Casual	52.2% (108/207)	41.7% (15/36)	52.0% (160/308)	
Exchange	13.5% (28/207)	22.2% (8/36)	11.0% (34/308)	
Had insertive anal sex (IAS)	61.0% (219/359)	61.5% (40/65)	59.9% (408/681)	0.92
Did not use a condom during IAS	30.1% (66/219)	37.5% (15/40)	25.5% (104/408)	0.17
Had receptive anal sex (RAS)	52.8% (189/358)	56.9% (37/65)	60.4% (411/681)	0.06
Did not use a condom during RAS	42.1% (80/190)	29.7% (11/37)	29.0% (119/411)	0.006
Relative age of partner				
Younger	31.2% (110/353)	41.5% (27/65)	34.0% (226/665)	0.30
Older	35.7% (126/353)	27.7% (18/65)	30.5% (203/665)	
Same age	33.1% (117/353)	30.8% (20/65)	35.5% (236/665)	
Knew HIV status of partner	64.1% (230/359)	70.8% (46/65)	65.5% (446/681)	0.57
Partner was HIV positive (among those who knew HIV status of partner)	4.4% (10/229)	73.9% (34/46)	5.6% (25/443)	<0.0001

Conclusions: Knowledge of HIV serostatus influences sexual behaviors among MSM, particularly through serosorting. However, over 60% of men surveyed had not been tested for HIV in the previous year and a third of men did not know the HIV status of their most recent partner. Prevention efforts should be tailored to reach those MSM who remain unaware of their HIV status.

1063 Use of the Seroadaptive Strategies of Sexual Positioning and Serosorting by MSM in Nigeria

Cristina M. Rodriguez-Hart[1]; Hongjie Liu[2]; Ifeanyi K. Orazulike[3]; Sam Zorowitz[4]; Sylvia Adebajo[5]; Lindsay Hughes[6]; Stefan Baral[7]; Merlin L. Robb[6]; William Blattner[1]; Manhattan Charurat[1]

[1]University of Maryland School of Medicine, Baltimore, MD, US; [2]University of Maryland School of Public Health, College Park, MD, US; [3]International Center on Advocacy and Rights to Health, Abuja, Nigeria; [4]Massachusetts General Hospital and Harvard Medical School, Boston, MA, US; [5]Population Council, Abuja, Nigeria; [6]US Military HIV Research Program, Bethesda, MD, US; [7]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US

Background: Sexual positioning and serosorting are two seroadaptive strategies adopted by some men who have sex with men (MSM) as HIV harm reduction strategies. The current analysis investigated these factors among MSM in Nigeria, where rates of infection are 10 fold higher than in the general population, who participated in the TRUST study.

Methods: Using respondent-driven sampling, 392 eligible MSM were interviewed. A subject was considered to be engaged in sexual positioning if an HIV positive MSM who knew his status prior to the study reported only receptive anal sex for the previous 12 months or an HIV negative MSM who knew his status prior to the study reported only insertive anal sex for the previous 12 months. A subject was considered to be engaged in serosorting if he knew his HIV status prior to the study and reported having only sex partners of the same HIV status. Logistic regression with generalized estimating equations was used to analyze factors associated with engagement in positioning or serosorting.

Results: Of the 390 participants with HIV testing history and who were tested for HIV at baseline, 21% (85/390) were HIV positive and reported knowing their status, 29% (114/390) were HIV negative and reported knowing their status, 23% (89/390) were HIV positive and reported not knowing their status, and 25% (97/390) were HIV negative and reported not knowing their status.

Among HIV positive MSM who knew their HIV status, 21% (18/85) practiced receptive sex only. Among HIV negative MSM who knew their status, 39% (44/114) practiced insertive sex only. Engagement in sexual positioning was associated with older age (OR=2.15; 95%CI: 1.07-4.32), not being married to a woman (OR=2.94; 95%CI: 1.03-8.33), and communication with partners about HIV status (OR=1.84; 95%CI: 1.01-3.36). The 384 MSM who reported any sex partner data generated 1565 sex partner dyads. Serosorting took place only among 192 dyads (12%). Engagement in serosorting was associated with communication with partners about HIV status (OR=3.78; 95%CI: 2.12-6.75) and stronger friendship (OR=1.40; 95%CI: 1.11-1.76).

Table 1. Sexual positioning and serosorting by HIV testing history and HIV serostatus among men who have sex with men (MSM) in Abuja, Nigeria

	Ego Self-Reported Knowing their HIV Status Prior to the Study		Ego Self-Reported Not Knowing their HIV Status Prior to the Study	
	HIV+ Crude % (n)	HIV- Crude % (n)	HIV+ Crude % (n)	HIV- Crude % (n)
Sexual Positioning (n=number of egos)[a]	n = 85	n = 114	n = 89	n = 97
Ego's Sexual Position				
Only insertive (n=103)	15.3 (13)	38.6 (44)	16.9 (15)	32.0 (31)
Only receptive (n=81)	21.2 (18)	20.2 (23)	20.2 (18)	22.7 (22)
Dual Practice (n=201)	63.5 (54)	41.2 (47)	62.9 (56)	45.4 (44)
Serosorting (n= number of ego-alter dyads)[b]	n = 357	n = 452	n = 353	n = 403
Alter's HIV Status				
Positive (n=58)	12.6 (45)	1.3 (6)	1.1 (4)	.7 (3)
Negative (n=415)	19.0 (68)	32.5 (147)	26.3 (93)	26.6 (107)
Unknown (n=1092)	68.3 (244)	66.2 (299)	72.5 (256)	72.7 (293)

[a] 7 egos were excluded from the analysis of sexual positioning. Of the 7, sexual positioning could not be calculated for 5 egos and 2 egos reported being HIV+ and knowing this status before the study but tested negative for HIV at study baseline.
[b] 8 egos were excluded from the analysis of serosorting. Of the 8, 6 did not report information on any alters in their sexual network and 2 egos reported being HIV+ and knowing this status before the study but tested negative for HIV at study baseline.

Conclusions: With this low level of engagement in harm reduction strategies among Nigerian MSM, interventions that promote communication between sex partners to adopt harm reduction and engage the full spectrum of combination prevention strategies promoted by the TRUST intervention are a focus of ongoing study, including how to influence normative behaviors in sexual networks.

1104 The Lifetime Medical Cost Savings From Preventing HIV in the United States

Bruce R. Schackman[1]; John Fleishman[6]; Amanda Su[2]; Richard Moore[5]; Rochelle Walensky[2]; David Paltiel[3]; Milton Weinstein[4]; Kenneth Freedberg[2]; Kelly Gebo[5]; Elena Losina[2]

[1]Weill Cornell Medical College, New York, NY, US; [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [3]Yale School of Public Health, New Haven, CT, US; [4]Harvard School of Public Health, Boston, MA, US; [5]Johns Hopkins University School of Medicine, Baltimore, MD, US; [6]Agency for Healthcare Research and Quality, Rockville, MD, US

Background: Enhanced HIV prevention interventions, such as pre-exposure prophylaxis for high-risk individuals, require substantial investments. We sought to estimate the medical cost saved by averting one HIV infection in the United States.

Methods: We estimated lifetime medical costs in persons with and without HIV to determine the cost saved by preventing one HIV infection. We used a computer simulation model of HIV disease and treatment (CEPAC) to project CD4 cell count, antiretroviral treatment status, and mortality after HIV infection. Annual medical cost estimates for HIV-infected persons, adjusted for age, sex, race/ethnicity, and transmission risk group, were from the HIV Research Network (range $1,854-$4,545/month) and for HIV-uninfected persons were from the Medical Expenditure Panel Survey (range $73-$628/month). Results are reported as lifetime medical costs from the US health system perspective discounted at 3% (2012 US dollars).

Results: The estimated discounted lifetime cost for persons who become HIV infected at age 35 is $326,500 (60% for antiretroviral medications, 15% for other medications, 25% for non-drug costs). For individuals who remain uninfected, but at high risk for infection, the discounted lifetime cost estimate is $96,700. The medical cost saved by avoiding one HIV infection is $229,800. The cost saved would reach $338,400 if all HIV-infected individuals presented early and remained in care. Cost savings are higher taking into account secondary infections avoided and lower if HIV infections are temporarily delayed rather than permanently avoided.

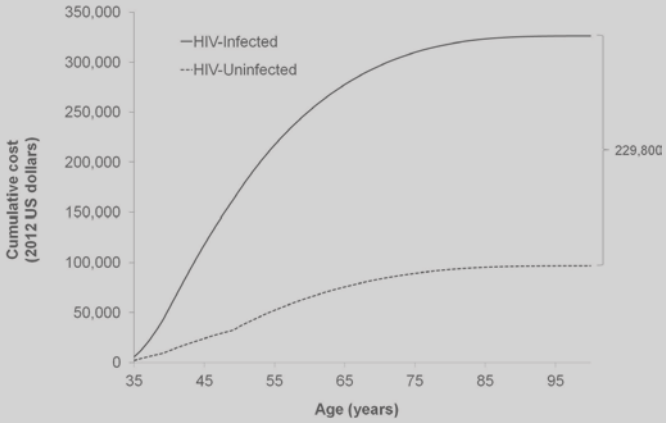


Figure 1: Cumulative discounted lifetime costs from time of infection at age 35 (2012 US dollars)

Conclusions: The potential medical cost savings from HIV prevention in the US are substantial given the high cost of HIV disease treatment.

1119 Survival Benefits Attributable to the Brazilian National ART Policy

Paula M. Luz[1]; Michael P. Girouard[2]; Beatriz Grinsztejn[1]; Kenneth Freedberg[2]; Valdilea Veloso[1]; Elena Losina[4]; Claudio Struchiner[1]; Robert Parker[2]; David Paltiel[3]; Rochelle Walensky[2]

[1]Fundacao Oswaldo Cruz, Rio de Janeiro, Brazil; [2]Massachusetts General Hospital, Boston, MA, US; [3]Yale School of Public Health, New Haven, CT, US; [4]Brigham and Women's Hospital, Boston, MA, US

Background: In Brazil, universal provision of antiretroviral therapy (ART) has been guaranteed free of charge to patients since 1996. We sought to quantify the survival benefits attributable to this policy.

Methods: We used a mathematical model of HIV disease (CEPAC-International) to estimate life expectancy of HIV-infected patients initiating ART between 1997 and 2013 in Brazil. We divided this timeframe into 5 eras, reflecting improvements in virologic and immunologic response to ART and in regimen sequencing over time. Input parameters were from the HIV Clinical Cohort at the Evandro Chagas Clinical Research Institute (Oswaldo Cruz Foundation) and from published Brazilian governmental data. Era-specific mean CD4 count at ART initiation ranged from 134/μL (Era 1) to 384/μL (Era 5). We included a loss to follow-up rate in each cohort of 10.1/1000 person-years. The 2014-censored and lifetime survival benefit attributable to each era were calculated as the sum of patients initiating ART in each cohort of a given era multiplied by the per-person survival increase attributable to ART in that era compared to pre-ART prophylaxis alone.

Results: In total, 556,829 individuals were estimated to have initiated ART in Brazil between 1997 and 2013 (Figure 1). Patients initiating ART in Era 1 had an estimated 2014-censored per-person life expectancy of 6.3 years compared to 2.9 years for pre-ART prophylaxis. Assuming no further improvements in care over time, projected lifetime per-person life expectancy increased from pre-ART (2.9 years) to 11.4, 17.0, 20.6, 23.7, and 25.7 years in Eras 1, 2, 3, 4, and 5, respectively. Total estimated population lifetime survival benefit for all persons starting ART from 1997 to 2013 in Brazil was 9.2 million life-years, with 1.3 million life-years realized as of 2014.

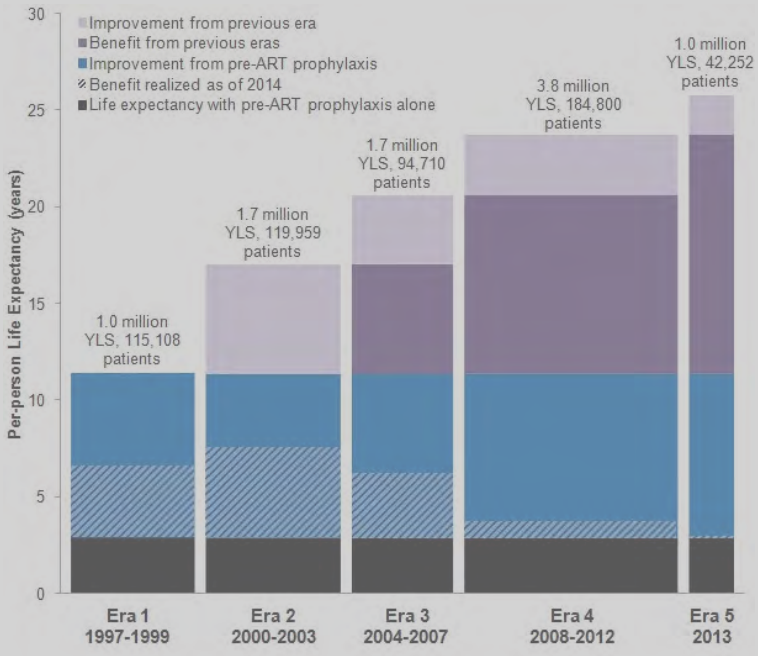

Figure 1. Years of life saved per person in each era produced by model simulations with a mean age at treatment initiation of 37 years (SD, 10 years). Bar width corresponds to the number of patients in each era and total colored area corresponds to lifetime survival benefits. Survival benefits realized as of 2014 are shaded with diagonal lines.

Conclusions: Brazil's national policy of free-of-charge ART access to patients has led to dramatic survival benefits, the vast majority of which have yet to be realized. Earlier HIV diagnosis, increased numbers accessing care, and improvements in ART regimens have all contributed substantially to these benefits.

1110 The Cost-Effectiveness of Early ART Initiation in South Africa: A Quasi-Experiment

Jacob Bor[1]; Ellen Moscoe[2]; Natsayi Chimbindi[3]; Kobus Herbst[3]; Kevindra K. Naidu[3]; Frank Tanser[3]; Deenan Pillay[3]; Till Barnighausen[3]

[1]Boston University School of Public Health, Boston, MA, US; [2]Harvard School of Public Health, Boston, MA, US; [3]Wellcome Trust Africa Centre for Health and Population Studies, Somkhele, South Africa

Background: Clinical trials are not well suited to evaluate the effectiveness and cost-effectiveness of interventions in "real world" settings. Using a quasi-experimental regression-discontinuity design (Bor et al. 2014), we establish the causal effect of early (vs. deferred) ART initiation on patient survival in rural South Africa, and obtain empirical (as opposed to modeled) cost-effectiveness estimates.

Methods: Demographic data from a large population surveillance in rural KwaZulu-Natal were linked to clinical records from South Africa's public sector ART program. 4391 patients enrolled in HIV care between 2007 and 2011. CD4 counts were collected upon entry into care regardless of ART initiation. Subjects were eligible for ART if CD4 < 200 cells/μL, as per national guidelines during this period. Dates of death were obtained from the demographic surveillance; dates of initiation and follow-up CD4 counts were obtained from clinical records. Patients were followed for up to five years. We estimated the causal effect of immediate ART eligibility on survival, immune health, and time spent in pre-ART and on ART, which were used to estimate costs. Effects were estimated using a regression-discontinuity design, which exploits the quasi-random nature of treatment assignment for patients with first CD4 counts close to the eligibility threshold. Patients just above vs. just below the threshold are similar on all observed *and unobserved* factors; but they receive different treatment assignments.

Results: Patients presenting with a CD4+ count just below 200 cells/μL were 4.3% points (95% CI 0.6, 8.0) more likely to be alive at two years compared to patients presenting with a CD4+ count just above the cut-off, an advantage that persisted at five years (Fig 1). These effects imply a 14.9% point two-year survival advantage for patients who actually initiated ART because they had an eligible CD4+ count. Large, persistent gains in clinical immune function were also observed among patients who were ART eligible. Over a five-year horizon, the additional medical care provided to ART-eligible patients implied a cost of $1967 per life year saved compared to treating patients with CD4+ counts close to 200 cells/μL.

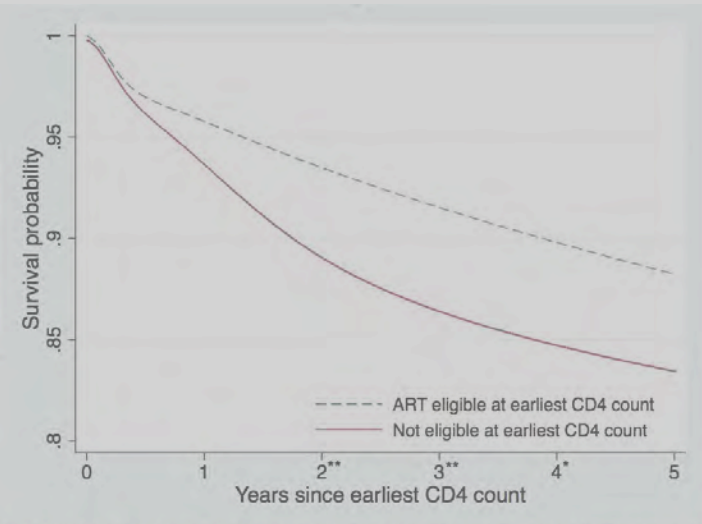

Fig 1. Predicted survival curves for patients with first CD4 counts just below (eligible) and just above (not eligible) the 200-cell threshold. Survival curves were estimated based on flexible-parametric survival models, adapted for use in regression discontinuity designs.

Reference: Bor J, Moscoe E, Mutevedzi P, Newell ML, Bärnighausen T. Regression discontinuity designs in epidemiology: causal inference without randomized trials. Epidemiology. 2014 Sep; 25(5):729-37.

Conclusions: In a real-world setting, referral of patients to pre-ART care (vs. immediate ART eligibility) led to large losses of life and health. These losses could have been avoided with immediate ART, which was found to be "very cost effective" at conventional benchmarks.

1111 Community-Based Strategies to Strengthen the Continuum of HIV Care Are Cost-Effective

Jennifer A. Smith[1]; Monisha Sharma[2]; Carol Levin[2]; Jared Baeten[2]; Heidi van Rooyen[3]; Connie Celum[2]; Timothy Hallett[1]; Ruanne V. Barnabas[2]

[1]Imperial College London, London, United Kingdom; [2]University of Washington, Seattle, WA, US; [3]Human Sciences Research Council, Sweetwaters, South Africa

Background: Closing gaps in the continuum of HIV care is a priority for public health strategies that aim to reduce HIV-associated morbidity, mortality and HIV incidence. Facility-based HIV counselling and testing (HTC) has achieved limited testing coverage and linkage to care, particularly among asymptomatic persons. Home HTC and linkage to care achieved high testing coverage and linkage to care in KwaZulu-Natal, South Africa, but its impact on population-level health and cost-effectiveness compared to existing facility-based testing has not been evaluated.

Methods: We developed an individual-based HIV transmission model parameterized with epidemiologic and cost data from home HTC and linkage studies in rural KwaZulu-Natal, South Africa. The HTC and linkage studies measured the change in the proportion of all HIV-positive persons with suppressed viral load between study enrolment and 12 months. The model simulated the intervention impact and projected the effect on health outcomes over 10 years. The incremental cost-effectiveness ratios (ICERs) were calculated for the intervention relative to existing facility-based testing per HIV incident infection and disability adjusted life year (DALY) averted.

Results: With the high coverage (91%) and linkage to ART (80%) observed in the home HTC studies, HIV-associated disability and incident infections were reduced compared to current testing modalities, especially at higher ART initiation criteria: as the ART initiation threshold increased from ≤200 cells/mm^3 to universal eligibility, 10-22% of DALYs and 11-48% of HIV infections were averted over ten years. Home HTC is "very cost effective" by WHO standards across all ART initiation thresholds: US$1,080, $925, $985 and $1,150 per DALY averted and $7,000, $7,580, $7,100 and $6,560 per infection averted with ART initiation at ≤200 cells/mm^3, ≤350 cells/mm^3, ≤500 cells/mm^3 and universal eligibility, respectively. ART costs exceeded all other costs, accounting for 48-85% of total programme costs; with universal eligibility and a reduced ART cost, the ICER per DALY averted is reduced four-fold.

Conclusions: Home HTC can strengthen linkage to care and enhance the increases in ART uptake that will result from South Africa's expanding ART eligibility criteria. As treatment programs move forward to implement '90% of HIV-infected persons tested, 90% treated, 90% achieving viral load suppression', insights from this analysis find that community-based HTC and linkage is a cost-effective strategy for HIV prevention.

1114 Global Fund Cost Projections for Implementing WHO 2013 Guidelines

Obinna Onyekwena; Ade Fakoya; Michael Johnson; Michael Olszak-Olszewski; Mark Dybul

The Global Fund to Fight AIDS, Tuberculosis and Malaria, Geneva, Switzerland

Background: Although recent global cost estimates indicate overall investments needed for implementation of the World Health Organization 2013 consolidated ART guidelines, detailed financial estimates for individual countries are limited. The aim of this study was to estimate additional costs for the transition of Global Fund grants to implement ART eligibility recommendations of the new guidelines.

Methods: The thirty-two countries which represent 83% of current Global Fund country allocations for HIV were included in the review. Data on treatment targets, ARV costs, and financing contributions to ARV were extracted from the Global Fund reporting database, grant documents and National AIDS Spending Assessment reports. Global projections for additional numbers of persons eligible for treatment, reported by WHO, were applied to country treatment targets to derive country-level number projections for 2015 to 2017. A weighted average ARV cost was used to determine associated ARV cost projections. Due to inter-program variability, facility and adherence support costs were not included. Treatment numbers and cost projections were disaggregated by new eligibility criteria and compared to current total allocations for HIV.

Results: ARV medicine cost for 2014 Global Fund commitments in 32 countries was estimated to be $628 million for 5 million patients on antiretroviral treatment. Additional cost of ARV medicines expected from ART eligibility recommendations was projected to be US$695 million to the end of 2017, for an additional 1.7 million persons on treatment. Costs for implementation of Option B+ and treating all HIV positive children below the age of five were US$53 million and US$106 million respectively; while initiating HIV positive persons with a CD4 count between 350 and 500 cells per mm^3 and in serodiscordant relationships had estimated additional costs of US$294 million and US$242 million respectively. The total ARV medicine cost projections represented approximately 41% (US$2.6 billion) of the total HIV allocations projected from 2015 to 2017 for the 32 countries analysed.

Conclusions: ARV medicine scale up costs alone will account for a significant portion of HIV resources allocated by the Global Fund to national HIV programs. This does not take into account additional facility and adherence support costs needed for quality service delivery. Understanding differential cost data in the implementation of treatment guidelines should strengthen strategic investments and portfolio optimisation.

Session O-10 Oral Abstracts — Room 6C

4:00 pm – 6:15 pm

New Antiretroviral Agents, Strategies, and HIV Drug Resistance

113LB Tenofovir Alafenamide (TAF) in a Single-Tablet Regimen in Initial HIV-1 Therapy

David Wohl[1]; Anton Pozniak[2]; Melanie Thompson[3]; Edwin DeJesus[4]; Daniel Podzamczer[5]; Jean-Michel Molina[6]; Gordon Crofoot[7]; Christian Callebaut[8]; Hal Martin[8]; Scott McCallister[8]

[1]University of North Carolina, Chapel Hill, NC, US; [2]Chelsea and Westminster Hospital, NHS Foundation Trust, London, United Kingdom; [3]AIDS Research Consortium of Atlanta, Atlanta, GA, US; [4]Orlando Immunology Center, Orlando, FL, US; [5]Hospital Universitari de Bellvitge, Barcelona, Spain; [6]Hopital Saint Louis, Paris, France; [7]Gordon Crofoot Research, Houston, TX, US; [8]Gilead Sciences, Inc, Foster City, CA, US; [9]Gilead Sciences, Inc, Foster City, CA, US

Background: Tenofovir alafenamide (TAF) is a novel tenofovir (TFV) prodrug that, when administered in the single tablet regimen elvitegravir/cobicistat/emtricitabine/TAF (E/C/F/TAF), has >4-fold increase in intracellular TFV diphosphate and >90% lower plasma TFV levels compared to tenofovir disoproxil fumarate (TDF). Two Phase 3 studies of identical design were conducted in distinct geographic areas comparing 2 single tablet regimens, E/C/F/TAF and E/C/F/TDF, in treatment-naïve HIV-1^+ adults.

Methods: Patients were randomized 1:1 to receive a single tablet regimen of E/C/F/TAF or E/C/F/TDF once daily in two Phase 3 double blind studies. Primary endpoint was Week 48 virologic response by FDA Snapshot algorithm in a pre-specified analysis of the combined studies.

Results: 1,733 subjects were randomized and treated: 15% women, 43% non-White, 23% viral load ≥100,000 copies/mL. Median baseline characteristics were: age 34 yrs, VL 4.58 $\log_{10}$c/mL, and CD4 count 427 cells/μL. The primary objective was met, as E/C/F/TAF was non-inferior to E/C/F/TDF with 92% and 90%, respectively, having HIV RNA <50 copies/mL at week 48 (difference +2%, 95% CI -0.7% to +4.7%, p=0.13). The rates of virologic success between E/C/F/TAF and E/C/F/TDF were similar across subgroups according to age, sex, race, baseline HIV1 RNA level, baseline CD4 cell count, region (US versus exUS), and study drug adherence. Mean change in CD4 count at Week 48 was 230 cells/μL in the E/C/F/TAF arm vs. 211 cells/μL for E/C/F/TDF (p=0.02). Virologic failure with resistance occurred in 0.8% in the E/C/F/TAF arm and 0.6% on E/C/F/TDF. Treatment related SAEs were rare: E/C/F/TAF 0.3% (n=3), E/C/F/TDF 0.2% (n=2). There were no reports of proximal renal tubulopathy (including Fanconi Syndrome) in either arm. No single AE led to discontinuation of more than 1 subject on E/C/F/TAF. Grade 2, 3, or 4 AEs occurring in ≥ 2% were: diarrhea (3.3% vs. 2.5%), nausea (2.2% vs. 2.0%), headache (2.9% vs. 2.1%), and URI (3.6% vs. 3.1%) in the E/C/F/TAF and E/C/F/TDF arms, respectively.

	E/C/F/TAF (n=866)	E/C/F/TDF (n=867)	p-value	Difference in Percentage (95% CI)
HIV-1 RNA < 50 at Week 48	800 (92.4%)	784 (90.4%)	0.13	2.0% (-0.7% to 4.7%)
Virologic Failure at Week 48	31 (3.6%)	35 (4.0%)		
HIV-1 RNA > 50	20 (2.3%)	23 (2.7%)		
Discontinued/lack of efficacy	2 (0.2%)	3 (0.3%)		
Discontinued/other, last VL > 50	8 (0.9%)	8 (0.9%)		
Added new ARV	1 (0.1%)	1 (0.1%)		
No data in window	35 (4.0%)	48 (5.5%)		
Discontinued due to AE/death	8 (0.9%)	14 (1.6%)		
Discontinued/other, last VL < 50	21 (2.4%)	31 (3.6%)		
Missing data/on study drug	6 (0.7%)	3 (0.3%)		
Virologic failure with drug resistance	7 (0.8%)	5 (0.6%)		

Conclusions: Through 48 weeks of treatment, high virologic response rates were seen in patients receiving E/C/F/TAF or E/C/F/TDF, and similar responses were seen across subgroups evaluated. Drug resistance was <1%. Both regimens were well tolerated, and no unique AEs associated with TAF occurred. These data support the use of E/C/F/TAF, the first TAF-based single tablet regimen, as a potential new regimen for initial treatment of patients with HIV-1 infection.

114LB Antiviral Activity/Safety of a Second-Generation HIV-1 Maturation Inhibitor

Carey Hwang[1]; Dirk Schürmann[2]; Christian Sobotha[2]; Heather Sevinsky[1]; Palanikumar Ravindran[1]; Hong Xiao[1]; Neelanjana Ray[1]; Mark Krystal[3]; Ira B. Dicker[3]; **Max Lataillade**[3]
[1]Bristol-Myers Squibb, Princeton, NJ, US; [2]Charité Research Organisation GmbH, Berlin, Germany; [3]Bristol-Myers Squibb, Wallingford, CT, US

Background: BMS-955176 is a 2nd-generation HIV-1 maturation inhibitor (MI). A 1st generation MI (bevirimat) showed clinical efficacy in early-phase studies, but ~50% of subjects had reduced viral susceptibility associated with naturally occurring polymorphisms in Gag. We assessed BMS-955176 antiviral activity, safety, and exposure–response during 10 days of monotherapy in HIV-1, subtype B-infected subjects.

Methods: AI468002 (NCT01803074) is a Phase 2a, randomized, multi-part trial. Forty HIV-1, subtype B-infected subjects with HIV-1 RNA ≥5000 c/mL and CD4+ T-cell counts ≥200 cells/μL were randomized 1:1:1:1 to BMS-955176 dose groups of 5, 10, 20 or 40 mg, then 4:1 to receive an oral suspension of BMS-955176 or placebo once daily (QD) for 10 days. Twenty additional subjects were later randomized to 80 and 120 mg QD dose groups. The primary endpoint was change in HIV-1 RNA from baseline to Day 11; safety and exposure–response were secondary endpoints.

Results: Overall, 60 subjects were randomized to receive either BMS-955176 (n=48) or placebo (n=12). Median change in HIV-1 RNA from baseline to Day 11 ranged from –0.15 to –1.36 $\log_{10}$ c/mL and maximum median change between baseline and Day 24 (study discharge) ranged from –0.50 to –1.70 $\log_{10}$ c/mL across the BMS-955176 groups. An exposure–response relationship was observed; there was an increase in maximum median response over the range of 5–40 mg QD, which plateaued at ~–1.64 $\log_{10}$ c/mL at doses of 40–120 mg QD. Maximum median declines in HIV-1 RNA were similar for the 40–120 mg QD dose groups regardless of baseline Gag polymorphisms (positions evaluated: V362, Q369, V370, and T371). BMS-955176 was generally well tolerated at all doses. There were no deaths, serious adverse events (SAEs), AEs leading to discontinuation, grade 3–4 related AEs or clinically relevant grade 2–4 laboratory abnormalities.

Conclusions: BMS-955176 achieved maximum median declines of >1 $\log_{10}$ c/mL in HIV-1 RNA at doses of 20–120 mg QD. Response increased with doses up to 40 mg QD, with a plateau of ~–1.64 $\log_{10}$ c/mL observed at 40–120 mg QD. The greatest response achieved was a maximum median change of –1.70 $\log_{10}$ c/mL in the 40 mg group. Unlike 1st-generation MIs, in this proof-of-concept study BMS-955176 showed similar antiviral activity in subjects with wild-type HIV-1 or HIV-1 with Gag polymorphisms. BMS-955176 was generally well tolerated at all doses. Phase 2b studies for BMS-955176 will begin Q2, 2015.

115LB Early ART and IPT in HIV-Infected African Adults With High CD4 Count (Temprano Trial)

Christine Danel[1]; Raoul Moh[2]; Delphine Gabillard[1]; Anani Badje[4]; Jerome Le Carrou[1]; Gerard M. Kouame[4]; Jean Baptiste Ntakpe[4]; Hervé Ménan[3]; Serge Eholie[2]; Xavier Anglaret[1]
On behalf of the Temprano Study Group
[1]Inserm, Bordeaux, France; [2]Université Felix Houphouet Boigny, Abidjan, Côte d'Ivoire; [3]CHU de Treichville, Abidjan, Côte d'Ivoire; [4]Programme PACCI, Abidjan, Côte d'Ivoire

Background: We present the final results of the Temprano ANRS 12136 trial that assessed the benefits of early ART and/or early 6-month isoniazid prophylaxis (IPT, 300 mg/day) among HIV-infected adults with high CD4 counts and no WHO criteria for starting ART.

Methods: Temprano was a randomized 2x2 factorial superiority trial conducted in 9 HIV care centers in Côte d'Ivoire from March 2008 through January 2015. Inclusion criteria were: HIV-1 infection, age ≥18 years, CD4 nadir ≤800/ul, and no criteria for starting ART according to the most recent WHO guidelines. Participants were randomized to one of four arms: ART initiation according to WHO criteria (WHOART); immediate 6-month IPT plus ART initiation according to WHO criteria (WHOART-IPT); immediate ART initiation (EarlyART); immediate 6-month IPT plus immediate ART initiation (EarlyART-IPT). First-line ART consisted of tenofovir plus emtricitabine plus either efavirenz, zidovudine or lopinavir/ritonavir. The primary endpoint was severe HIV morbidity (AIDS-defining diseases, non-AIDS-defining malignancy, or non-AIDS-defining invasive bacterial diseases),or any-cause mortality at 30 months. The secondary endpoint was any other grade 3-4 defining morbidity. We used multivariate Cox proportional models to compare outcomes between the WHOART and EarlyART arms, and between the IPT and no IPT arms. We tested for interaction between earlyART and IPT.

Results: Of 2,076 patients randomized, 2,056 were included in the analysis (78% were women; 91% classified at WHO stage 1-2; median age 35 years; median CD4 nadir 465/ul; median HIV-1 viral load 4.7 $\log_{10}$ copies/ml). They were followed for 4,755 patient-years, during which 47 died, 175 experienced 204 episodes of severe morbidity (TB 85, invasive bacterial diseases 56, other AIDS-defining diseases 11, non-AIDS malignancy 5), 287 experienced 364 episodes of severe grade 3-4 morbidity (hematologic 256, hepatic 31 renal, 22, cardiovascular 9, others 46), and 44 (2.2%) were lost-to-follow up. There was no interaction between EarlyART and IPT. The risk of severe morbidity was 44% lower with EarlyART vs. WHOART (Table) and 35% lower with IPT vs. no IPT. EarlyART significantly decreased morbidity overall and when restricted to patients with baseline CD4 >500/ul. The risk of Grade 3-4 morbidity did not differ between strategies.

Severe morbidity	N	TAR (PY)	Rate (/100PY)	AHR	(95% CI)
Overall					
WHOART	111	2,247	4.94		
EarlyART	64	2,310	2.77	0.56	(0.41 - 0.76)
No IPT	104	2,225	4.67		
IPT	71	2,332	3.04	0.65	(0.48 - 0.88)
Baseline CD4 >500/ul					
WHOART	38	918	4.14		
EarlyART	23	964	2.39	0.56	(0.33 - 0.93)
No IPT	37	918	4.03		
IPT	24	965	2.49	0.61	(0.37 - 1.02)

N: number of events. PY: person-years; TAR: time at risk; AHR: adjusted hazard ratio; CI: confidence interval

Conclusions: In Côte d'Ivoire, both immediate ART and IPT dramatically and independently decreased the risk of severe morbidity, and should be recommended as the standard of care for HIV.

116 Antiretroviral Drug Screening Provides Key Insights Into HIV Drug Resistance

Iris Chen[1]; Matthew B. Connor[2]; William Clarke[1]; Mark A. Marzinke[1]; Vanessa Cummings[1]; Sheldon D. Fields[3]; Darrell P. Wheeler[4]; Kenneth H. Mayer[5]; Beryl A. Koblin[6]; Susan H. Eshleman[1]
[1]Johns Hopkins University School of Medicine, Baltimore, MD, US; [2]Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US; [3]Florida International University, Miami, FL, US; [4]Loyola University Chicago, Chicago, IL, US; [5]Fenway Health, Boston, MA, US; [6]New York Blood Center, New York, NY, US

Background: The HIV Prevention Trials Network (HPTN) 061 study enrolled HIV-infected and HIV-uninfected Black men who have sex with men in six cities in the United States who were at a high risk of HIV infection. Most of the HIV-infected men in the study reported that they were unaware of their HIV status or that they were aware of their status but were not in care. HIV drug resistance was detected in 48 (28.4%) of 169 HIV-infected men who were not virally suppressed at study enrollment. We used a high-throughput assay to screen for the presence of antiretroviral (ARV) drugs in samples from these study participants.

Methods: Plasma samples were obtained at the HPTN 061 enrollment visit from the 169 HIV-infected men described above. Samples were tested for the presence of 15 ARV drugs using a qualitative assay based on high-resolution mass spectrometry. Self-reported data on prior and current ARV drug use for pre-exposure prophylaxis, post-exposure prophylaxis, and ARV treatment were collected in the HPTN 061 study.

Results: ARV drugs were detected in 60 (35.5%) of the 169 men, including 27 (56.3%) of the 48 men who had drug-resistant HIV. Eighteen (37.5%) of those 48 men had at least one ARV drug detected that was not consistent with their drug resistance mutations. Unusual combinations of ARV drugs were detected in some samples. Thirty-one of the 137 men who reported no prior or current ARV drug use had drug-resistant HIV; based on these data alone (self-reported ARV drug use and resistance testing), the estimated rate of transmitted drug resistance (TDR) was 22.6%. However, 14 of the men with drug-resistant HIV also had at least one ARV drug detected. After excluding those men, the estimated rate of TDR was 12.4%. Five (29%) of the 17 men with TDR had multi-class drug resistance.

Conclusions: ARV drug testing can provide important information relevant to the emergence and transmission HIV drug resistance. In addition to the high levels of drug resistance previously observed in this cohort, ARV drug testing indicated that a significant portion of the men were at risk of acquiring additional drug resistance mutations. ARV drug testing also provided a more accurate estimate of TDR by identifying men who were using ARV drugs but chose not to disclose this to study staff. These findings demonstrate the benefit of combining HIV drug resistance testing with ARV drug testing for the analysis of HIV drug resistance.

117 Untimed Drug Levels and Resistance in Patients Experiencing Low-Level HIV Viremia

Alejandro Gonzalez-Serna; Luke C. Swenson; Adriana Nohpal; Birgit Watson; Kate Auyeung; Julio Montaner; Richard Harrigan
BC Centre for Excellence in HIV/AIDS, Vancouver, Canada

Background: HIV resistance testing in HAART patients experiencing low-level viremia (LLV, 50-999 HIV-RNA copies/mL) predicts the risk of subsequent virologic failure (VF, ≥1000 copies/ml). Suboptimal plasma drug levels can arise as a result of poor adherence and/or pharmacokinetic issues. Here, our aim was to evaluate whether retrospective analysis of plasma levels also provides insight into patient outcomes after experiencing LLV.

Methods: The first documented LLV episode of 2176 patients was analyzed. A total of 328 consenting patients with drug levels, genotypic resistance data and with follow-up clinical data while on constant therapy available were eligible. Untimed plasma drug levels (UDL) of PIs and NNRTIs in the sample corresponding to the first LLV episode were measured by HPLC-tandem MS. Drug levels were categorized as 'therapeutic' or 'suboptimal' based on target trough concentrations from DHHS guidelines. Resistance was assessed using the Stanford algorithm (GSS, corresponding to the number of 'active' drugs prescribed). Time to VF after LLV was evaluated by Kaplan–Meier analysis and Cox proportional hazards regression.

Results: 78 of 328 patients (24%) had suboptimal drug levels at LLV, compared with 63 (19%) having GSS<3. Both suboptimal UDL and GSS<3 independently increased the risk of future pVL >1000. Within a year, 56/78 (72%) patients with suboptimal UDL had failed, compared to 45/63 (71%) with GSS <3 and to 103/206 (50%) with both optimal GSS and UDL. Of those with suboptimal UDL, 43/78 (55%) had undetectable levels of PI/NNRTI, with most (81%) failing by one year. Only 18 patients had both suboptimal UDL and GSS<3.

In the adjusted multivariable model, variables associated with VF were suboptimal UDL (Adjusted Hazard Ratio, AHR 2.9, 95%CI 2.0-4.2, p<0.001), female gender (AHR 1.9, 95%CI 1.3-2.9, p=0.001), GSS<3 (AHR 1.5, 95%CI 0.9-2.3, p=0.098) and being HAART-naïve (AHR 1.7, 95%CI 1.1-2.7, p=0.031). When UDL and GSS categories were combined, the lowest VF was found for optimal UDL &GSS≥3 (P<0.001). Numerous sensitivity analyses confirmed these findings.

Conclusions: A single untimed drug level (UDL) and GSS independently predict subsequent VF, with suboptimal UDL having a greater hazard than GSS<3, especially if drug levels are undetectable. Together, UDL and GSS can explain a higher proportion of treatment failures than either measure alone. These results could justify the potential investigation of UDL in prospective of management of LLV.

118 Pretreatment HIV Drug Resistance Increases Regimen Switch in Sub-Saharan Africa

Tamara Sonia Boender[1]; Bernice M. Hoenderboom[1]; Kim C. Sigaloff[1]; Maureen Wellington[2]; Margaret Siwale[3]; Cissy M. Kityo[4]; Alani Sulaimon Akanmu[5]; Mariette E. Botes[6]; Tobias F. Rinke de Wit[1]
On behalf of the PASER Study Group

[1]*Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands;* [2]*Newlands Clinic, Harare, Zimbabwe;* [3]*Lusaka Trust Hospital, Lusaka, Zambia;* [4]*Joint Clinical Research Centre, Kampala, Uganda;* [5]*Lagos University Teaching Hospital, Lagos, Nigeria;* [6]*Muelmed Hospital, Pretoria, South Africa*

Background: After the successful scale-up of antiretroviral therapy (ART) in Africa, there are concerns about emerging drug-resistant HIV and an increasing need for more costly second-line regimens. We investigated the impact of pretreatment drug resistance (PDR) on 2 and 3 year ART outcomes and switch to second-line in the first 3 years of ART within the Pan-African Studies to Evaluate Resistance Monitoring (PASER-M) cohort.

Methods: The PASER-M cohort followed HIV-1 infected individuals initiating first-line ART for 2 years (13 sites) or 3 years (5 sites) in 6 African countries. Viral load (VL) and *pol* genotypic testing (if VL>1000 cps/ml) was performed at ART initiation and annually thereafter. PDR was defined as a decreased susceptibility to at least one prescribed drug, using the Stanford algorithm and IAS-USA mutation list. The effect of PDR on (I) switch to second-line with acquired drug resistance, (II) virological failure (VL>400 c/ml) and (III) acquired drug resistance during the first 3 years of ART was assessed using cumulative incidence plots, multivariate cox-models and multilevel logistic regression. Unnecessary switch was defined as switch with VL<1,000 cps/ml or VL>1,000 cps/ml with wild-type virus.

Results: For 2,579 (94.2%) of 2,737 participants genotypes were available at ART initiation; in 5% (n=139) PDR was present. After 3 years, 112 (4.3%) participants had switched to second-line regimen of whom 78 (69.6%) had VL results and genotypes available; 33.3% (n=26) switched unnecessarily. Most switches with drug resistance took place after 1 year of ART (figure). Incidence density of switch was 1.1 per 100 person-years. PDR increased the risk of: (I) switch with drug resistance, subhazard ratio 7.8 (95%CI 3.9-15.6) during 3 years; (II) virological failure, odds ratios (OR) 2.9 (95%CI 1.4-5.8) after 2 years and 2.8 (95%CI 1.1-7.2) after 3 years, and (III) acquired drug resistance, OR 2.5 (95%CI 1.2-5.4) after 2 years and OR 5.0 (95%CI 1.8-14.3) after 3 years of first-line ART. PDR was not associated with mortality or new AIDS events.

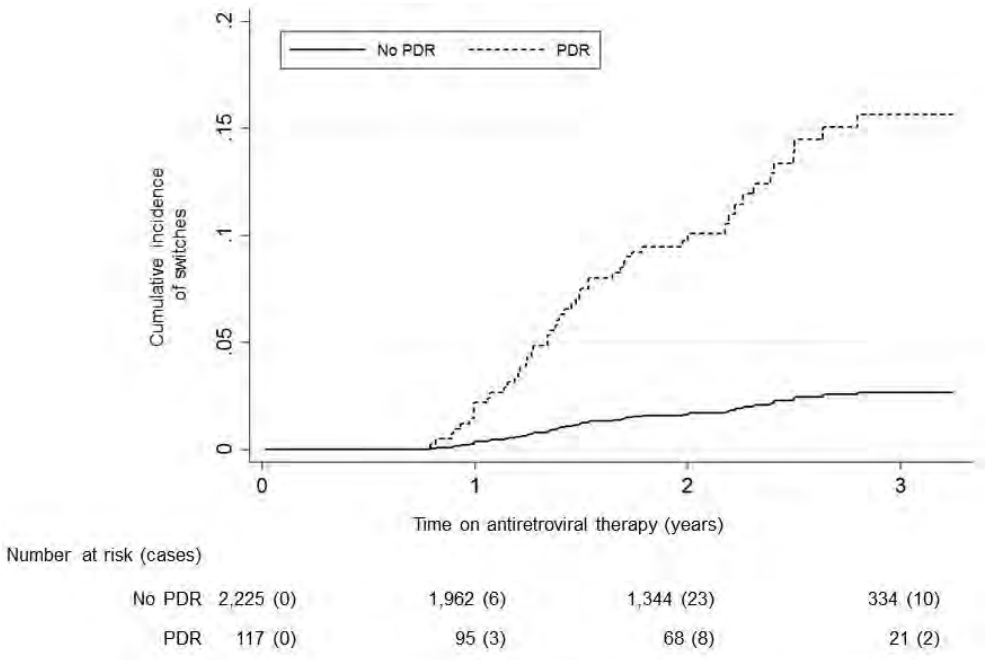

Figure. Cumulative-incidence curve of switches to second-line antiretroviral therapy, by pretreatment drug resistance (PDR).
Switch is defined as a change to second-line regimen with acquired drug resistance.

Conclusions: PDR is strongly associated with switching to second-line ART, but does not cause excess mortality or AIDS related events. VL monitoring can enable timely detection of therapy failure and avoid unnecessary switches. In view of rising PDR levels in Africa, these findings have important implications for allocation of ART resources and renders mitigating PDR a priority.

119 Impact of NRTI Cross-Resistance on Second-Line PI + NRTI Therapy Outcomes in Africa

Nicholas Paton[1]; Cissy Kityo[2]; Jennifer Thompson[5]; Leonard Bagenda[2]; James Hakim[6]; Joep van Oosterhout[4]; Andrew D. Kambugu[3]; Anne Hoppe[5]; Sarah Walker[5]
On behalf of the EARNEST Trial Team

[1]National University of Singapore, Singapore, Singapore; [2]Joint Clinical Research Centre, Kampala, Uganda; [3]Infectious Diseases Institute, Kampala, Uganda; [4]University of Malawi, Blantyre, Malawi; [5]MRC Clinical Trials Unit at University College London, London, United Kingdom; [6]University of Zimbabwe Clinical Research Centre, Harare, Zimbabwe

Background: Extensive NRTI resistance, common at the time of switch to second-line therapy in ART programme settings, is expected to affect outcomes. We examine the impact of baseline NRTI resistance on responses to PI+NRTIs in the EARNEST trial.

Methods: 1277 patients aged ≥12y who met WHO-defined treatment failure criteria after >12 months on NNRTI-based first-line ART in African rollout programmes were randomised to receive bPI (standardised to lopinavir/ritonavir 400mg/100mg bd) with either 2/3 NRTIs selected by clinician based on algorithms without resistance testing (PI/NRTI); with raltegravir (RAL 400mg bd)(PI/RAL), or as monotherapy (+RAL induction for first 12 weeks)(PI-mono). PI-mono was stopped after 96 weeks; other groups continued randomised treatment to week 144. Drug resistance at baseline (done in 391/426 in PI/NRTI) and VL during study were tested retrospectively on stored samples (results blinded during trial).

Results: Patients had advanced treatment failure (42% VL≥100,000 c/ml, 62% CD4<100 cells/mm^3) at baseline. In PI/NRTI, 80% received TDF+3TC/FTC (±ZDV). Based on resistance testing, the PI/NRTI regimen contained 0 predicted active NRTIs (at most low-level resistance, Stanford criteria) in 230 (59%, PI/NRTI(0)), 1 active NRTI in 128 (33%, PI/NRTI(1)) and ≥2 active NRTIs in 33 (8%, PI/NRTI(2)). VL suppression in PI/NRTI(0) was markedly superior to PI-mono (76% vs 44% respectively <50 c/ml at week 96; P<0.001), and similar to PI/RAL (76% vs 72% <50 c/ml for PI/NRTI(0) and PI/RAL respectively at week 144, P=0.28, Figure). Response in PI/NRTI(1) was identical to PI/NRTI(0) (both 76% < 50 c/ml at week 144; P=0.92) but slightly lower in PI/NRTI(2) (62% < 50 c/ml; P=0.12 vs PI/NRTI(1)).

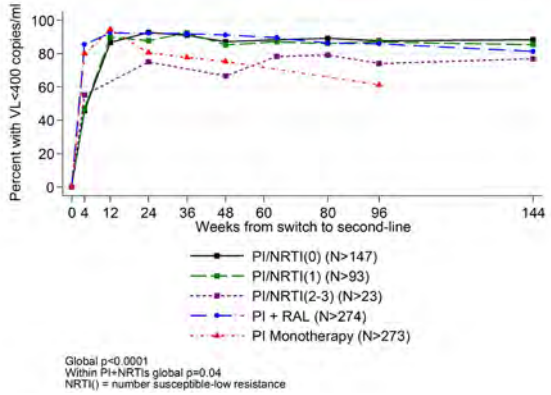

Figure: VL suppression in PI/NRTI arm by genotype-predicted NRTI activity, compared to supression in PI/RAL and PI-mono arms

Conclusions: Even when there is little or no predicted activity due to resistance, NRTIs make a major contribution to efficacy of PI/NRTI second-line therapy with clear added activity over the PI alone, equivalent to adding a drug from a new class. No difference between 0 and 1 active NRTIs suggests this contribution is not due to direct drug activity (possibly represents a viral fitness effect). The paradoxical trend to worse outcome with 2 active NRTIs may reflect a small group of patients with very poor adherence on first-line, continued during second-line. Algorithmic NRTI drug selection and attention to adherence are likely to achieve optimal outcomes in standardised PI/NRTI second-line therapy in resource-limited settings with resistance testing to select NRTIs of little added value.

120 Fitness Effects of Drug-Resistant Strains Across the United States HIV-1 Transmission Network

Joel O. Wertheim[1]; Alexandra M. Oster[2]; Neeraja Saduvala[2]; Walid Heneine[2]; Jeffery A. Johnson[2]; William M. Switzer[2]; Angela L. Hernandez[2]; H. Irene Hall[2]

[1]University of California San Diego, San Diego, CA, US; [2]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, US

Background: Drug resistance associated mutations (DRAMs) can reduce the effectiveness of antiretrovirals (ARVs). DRAMs from multiple drug classes can have deleterious effects on intrahost viral fitness (replication) and may reduce transmissibility. We used genetic transmission network analysis to assess the effect of DRAMs on interhost viral fitness (transmission, or network links).

Methods: We analyzed 66,235 HIV-1 *pol* sequences reported to the US National HIV Surveillance System for persons diagnosed through 2012; 30,200 were collected within 3 months of diagnosis in ARV-naïve persons. We aligned all sequences to a reference sequence (HXB2), removed DRAM-associated codons, and constructed a transmission network by linking sequences with ≤1.5% Tamura-Nei genetic distance, indicating potential transmission between two persons. Among ARV-naïve persons, we determined the percentage that clustered with ≥1 sequence, by presence of DRAMs, overall and by drug class, and conducted multivariable analysis to account for potential confounders.

Results: Of 30,200 ARV-naïve persons, 12,539 (42%) clustered. Protease and non-nucleoside reverse transcriptase inhibitor DRAMs were not associated with clustering. However, nucleoside reverse transcriptase inhibitor (NRTI) DRAMs were associated with reduced clustering (33% with NRTI DRAMs clustered vs. 42% without NRTI DRAMs, $p<0.0001$). After adjusting for age, race/ethnicity, transmission category, geographic region, and diagnosis year, having NRTI DRAMs was still associated with reduced clustering. No single mutation appears responsible for the reduced clustering. M184V, which has known deleterious intrahost fitness consequences, was associated with a lower prevalence of clustering (18%) and was present in only 8% of persons with an NRTI DRAM. Persons in the 7 largest DRAM clusters (≥30 person, ≥90% sharing a mutation) did not differ significantly from those in the 26 largest non-DRAM clusters (≥30 person) with respect to sex, race/ethnicity, or transmission category. However, persons in DRAM clusters were significantly more likely to be diagnosed in the last 3 years of the analysis period. These DRAM clusters contained mutations from all three drug classes.

Conclusions: With the exception of NRTI mutations, DRAMs did not have deleterious effects on interhost transmission. Our findings likely reflect compensatory mechanisms that improve fitness or insignificant impact of DRAMs on transmissibility and highlight the propensity for drug-resistant HIV-1 to spread.

121 Dolutegravir Resistance Requires Multiple Primary Mutations in HIV-1 Integrase

Arne Frantzell; Christos J Petropoulos; **Wei Huang**

Monogram Biosciences, South San Francisco, CA, US

Background: HIV-1 integrase sequences containing mutations at positions 143, 148 and 155 represent major resistance pathways to integrase inhibitors (INI). These genetic pathways are generally distinct for raltegravir and elvitegravir; the emergence of more than one primary mutation in a single virus genome is rarely observed. In a clinical trial, the viruses of four of seven virologic failure cases treated with a dolutegravir (DTG) based regimen contained combinations of mutations at positions 143, 148 and 155. To understand how the combined effects of primary mutations enable HIV to escape DTG drug pressure, we examined the impact of combinations of primary mutations on DTG susceptibility and replication capacity, with and without additional secondary mutations.

Methods: A series of laboratory viruses containing site directed mutations at HIV-1 integrase positions 143, 148 and 155 alone, in combination, or with secondary mutations T97A or G140S, were constructed. INI susceptibility and replication capacity (RC) were determined using a pseudovirus luciferase reporter assay.

Results: Single mutations at positions 143, 148 or 155 alone did not confer reductions in DTG susceptibility. Double mutations Y143R+N155H and Q148H+N155H produced modest reductions in DTG susceptibility (FC=3.1, 4.2, respectively), whereas the Y143R+Q148H double mutations did not (FC=0.7). The addition of G140S, a Q148 pathway mutation, to the double mutants Y143R+Q148H and Q148H+N155H further reduced DTG susceptibility (FC=6.2, 35, respectively) and fully restored the RC of the Y143R+Q148H and Q148H+N155H viruses (RC=17%, 3%, respectively). In contrast, the addition of G140S dramatically decreased the RC of the Y143R+N155H mutant from 60% to 5%. The addition of T97A, a Y143 or N155 pathway mutation, to the Y143R+N155H mutant did not confer a further reduction in DTG susceptibility, but did reduce RC.

Conclusions: This study demonstrates that HIV-1 variants containing combinations of INI resistance mutations at positions 143, 148 and 155 exhibit reduced susceptibility to DTG. Viruses that harbor mutations belonging to the 148+155 escape pathway are less susceptible to DTG and exhibit similar or greater RC than viruses harboring mutations belonging to the 143+148 or 143+155 pathways. Thus, in the face of DTG pressure, HIV-1 variants with 148 and 155 mutations likely possess a replication advantage over variants with 143 and 148 mutations or 143 and 155 mutations.

Session S-4 Symposium — Room 613

4:00 pm – 6:00 pm

Making Sense of Sensing: Innate Immunity and HIV Infection

122 Role of Tetherin in the Evolution and Spread of HIV-1

Daniel Sauter

Ulm University Medical Center, Ulm, Germany

The interferon-inducible protein tetherin (also known as BST-2 or CD317) has emerged as a key component of the intrinsic immunity against retroviruses. Initially, tetherin was shown to restrict HIV-1 in the absence of the viral protein U (Vpu) by inhibiting the release of budding virions from infected cells. More recently, it has become clear that tetherin also acts as a pattern recognition receptor inducing NF-κB-dependent expression of antiviral and proinflammatory genes in HIV infected cells. Notably, tetherin does not only restrict retrovirus release but has activity against diverse enveloped viruses including Arena-, Filo- and Herpesvirues. Whereas the ability to restrict virion release is highly conserved among mammalian tetherin orthologs and probably an ancient function of this protein, innate sensing seems to be unique to the human and chimpanzee orthologs and thus an evolutionarily recent activity. The potent and broad antiviral activity of tetherin has driven the evolution of antagonists in many viruses. Simian (SIV) and human immunodeficiency viruses, for example, use at least three different proteins (Nef, Vpu or Env) to antagonize tetherin. The continuous arms race of tetherin with viral antagonists is probably also the reason for a unique deletion in the cytoplasmic tail of human tetherin that renders it resistant against SIV Nef. Since most SIVs - including the direct precursors of HIV-1 - use Nef to antagonize tetherin in their respective hosts, human tetherin poses a significant barrier to successful cross-species transmissions to humans. Interestingly, the four groups of HIV-1 (M, N, O and P) which arose from independent cross-species transmissions, have evolved different mechanisms to overcome this hurdle. Whereas pandemic HIV1 group M viruses switched from Nef to Vpu to counteract human tetherin, rare group P and N Vpus do not or only poorly antagonize this restriciton factor. In contrast, Nef

proteins of epidemic HIV1 group O viruses target a region adjacent to the deletion in human tetherin to increase virion release from infected CD4+ T cells. Thus, potent tetherin counteraction may be a prerequisite for the efficient spread of lentiviruses in the human population. The coevolution of tetherin with primate lentiviruses, the molecular mechanisms underlying its antagonism and implications for spread and pathogenesis of human immunodeficiency viruses will be presented.

123-A Innate Sensing of HIV-1 in Macrophages

Martin R. Jakobsen

Aarhus University, Aarhus C, Denmark

Given the important role of cytosolic DNA in stimulating innate immune responses, there is an intense interest in defining the sensors of HIV DNA and the cellular mechanisms underlying subsequent induction of Interferon (IFN). The innate immune response is orchestrated in a complex manner where various pathogen recognition receptors scavenge for pathogen associated molecular patterns. Within the last years our understanding of how HIV is sensed by immune cells has increased significantly. The major break-through was the identification of cyclic GMP-AMP (cGAMP) synthetase (cGAS) as the innate sensor of foreign DNA. Activation of cGAS initiates the production of cGAMP, which in turn acts as the second messenger binding to the ER-bound protein STING and triggering IFN production. The role of cGAS as the pivotal DNA sensor is very compelling and supported by in vitro data, crystal structures, and a strong phenotype of cGAS-deficient mice. Accumulating evidence suggests, however, that another DNA sensor, Interferon gamma inducible factor 16 (IFI16), also play a key role in the recognition of HIV DNA. IFI16 was originally described as a nuclear protein involved in the regulation of transcription, and chromatic remodeling. In 2010 it was shown, however, that cytosolic IFI16 is responsible for recognizing HSV-1 DNA (Unterholzner, Nature Immunology, 2010). At the same time as cGAS was described as a HIV sensor (Gao et al. Science 2013), we demonstrated that IFI16 was critical for triggering innate immune responses against HIV in macrophages and that IFI16 depletion significantly increased HIV replication (Jakobsen et al, PNAS 2013). More recent data now suggest that IFI16 may also play an essential role in the depletion of CD4+ T cells by recogniting reverse transcriptase intermediates from abortive infections, which lead to caspase-1 activation and IL-1ß release (Doitsh et al. Nature 2014).

In conclusion, IFI16 and cGAS clearly play key roles in sensing HIV, but perhaps even more importantly, we now know that recognition of HIV triggers robust antiviral and inflammatory responses, as well as cell death mechanisms that impact HIV immunopathogenesis. In this talk, I will discuss the interplay between HIV-1 infection and cytosolic PRRs recognition. Furthermore, I will touch upon new interesting functions of IFI16 in the cGAS-STING pathway and in directly suppressing HIV transcription.

124 Innate Sensing and Signaling to HIV-1 in Dendritic Cells

Teunis Geijtenbeek

Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands

Dendritic cells (DCs) are central players in the induction of innate and adaptive immunity to HIV-1. Innate sensing of pathogens by pattern recognition receptors (PRRs) triggers signaling pathways that lead to the induction of DC maturation, antiviral type I IFN responses and cytokine responses, and subsequent induction of specific T helper cell differentiation and adaptive immunity. It is becoming clear that early innate immune responses greatly affect susceptibility as well as chronic disease progression. Our recent data have uncovered an important role for type I IFN responses in the induction of follicular T helper cells, which can affect disease progression by inducing strong antibody responses. However, several viruses including HIV-1 have developed strategies to prevent innate sensing and/or innate signaling and identification of these mechanisms greatly facilitate development of novel strategies to combat infections. Here I will discuss the role of innate signaling by different pattern recognition receptors, including DC-SIGN and TLR8, in infection of DCs and modulation of innate and adaptive immune responses. Recent data strongly sugges that although DCs are equipped with innate sensors for HIV-1, the virus has developed various strategies to either escape or counteract sensing and induction of antiviral immunity.

125 How HIV-1 Evades DNA Sensors

Vineet KewalRamani

National Cancer Institute, Frederick, MD, US

Retroviruses must replicate their genomes in the presence of cytosolic DNA sensors capable of triggering an antiviral response. Here we demonstrate that HIV-1 reverse transcribed DNA products are shielded from cytosolic DNA sensors by the HIV-1 core. Treatment of HIV-1 infected cells with the capsid-binding drug PF-3450074 releases DNA products into the cytosol where they can stimulate the cGAS-STING pathway and produce a type I IFN response. HIV-1 coordinates reverse transcription and uncoating to minimize exposure of DNA products, and perturbation of either process can influence the ability of HIV-1 to induce a type I IFN response. Both wild-type and capsid-mutant HIV-1 isolates stimulate an antiviral response in macrophages that is dependent on viral DNA synthesis and impedes subsequent rounds of virus infection. Collectively, these results illustrate the interdependence of reverse transcription and uncoating, and the importance of coordinating these two viral activities to avoid immune stimulation.

Session S-5 Symposium — Room 6D

4:00 pm – 6:00 pm

Advancing HIV Prevention: Lessons from Biology, Medicine, and Public Health Law

126 The Biology of HIV Transmission: What We Think We Know and How We Know It

Julie M. Overbaugh

Fred Hutchinson Cancer Research Center, Seattle, WA, US

Biomedical prevention of HIV depends on blocking early events in the transmission process. Thus, designing and testing prevention strategies using appropriate model systems that mimic the biology of HIV transmission may help optimize the chances for success. There is, in fact, little direct information about the biology of HIV transmission in humans because this window is difficult to capture. However, plausible theories about this process can be inferred from studies of the properties of transmitted viruses and from early events in model systems. This lecture will discuss how these findings have helped inform our understanding of HIV transmission biology as well as the limitations of this knowledge.

127 HIV Phylogenetics: Lessons for HIV Prevention

Christophe Fraser

Imperial College London, London, United Kingdom

HIV phylogenetics, the study of viral genetic sequences, is used to track the spread of different viral lineages, and to identify likely transmission events, chains and clusters. Phylogenetics enhances HIV prevention science by quantifying the risk factors for onwards transmission, resolving epidemics into sub-epidemics, and identifying common routes of transmission. In discordant pair studies, such as HPTN 052, phylogenetics is used to determine whether transmission events could or could not have occurred within the studied couple. This increases the power and accuracy of such studies.

In concentrated epidemics, such as amongst MSM in Europe, phylogenetics has been used to characterize transmission patterns. After reviewing key results in the area, I will focus on recent phylogenetic studies conducted in the Netherlands, where the epidemic amongst MSM has been increasing in recent years. We determined the characteristics and dynamics of different transmission clusters, and found that the epidemic was diffuse, with a large number of clusters sharing similar dynamics. We find that the epidemic is continuously replenished by the formation of new clusters amongst younger individuals. Next, by zooming in on probable transmission pairs, we quantified transmission rates throughout the stages of infection, starting from acute infection and through the different stages of the care and treatment continuum. We found that HIV prevention requires a combination of improvements in take-up of testing, speedy treatment initiation, and rapid viral suppression.

I will conclude by describing next-generation sequencing data from different settings. Here, the whole viral genome is reconstructed, and a measure of diversity within samples is also obtained. Dual infection can be identified with relative ease, and is observed in all studied populations. These techniques yield large increases in phylogenetic resolution, such that sub-epidemics can be more clearly delineated. I will describe how phylogenetics is becoming part of the standard toolkit of HIV prevention studies.

All work described is joint work with the HIV Monitoring Foundation in Amsterdam, the BEEHIVE collaboration, the PANGEA-HIV consortium, the HPTN 071 study team, and my research group at Imperial College.

128 Optimizing ART: Treatment as Prevention in the US: Will It Be Enough?

Richard A. Elion

Whitman-Walker Health, Washington, DC, US

The success of treatment as prevention (TASP) for HIV has resulted in a significant reduction in rates of transmission. These declines are reflected in some municipalities as HIV incidence has diminished by upwards of 50% in some areas. These benefits have not been consistent across communities, as reflected through variable HIV suppression rates in the HIV treatment cascade in different communities. Nearly 90% viral suppression rates are seen in clinical trials, yet numerous models of HIV cascade success demonstrate viral suppression rates ranging from approximately 30% -70%. The impact of treatment as prevention is clear in cities where this approach has been widely adopted, but the declines in HIV incidence level off within 2 years and plateau.

These benefits are substantial, but inadequate if our goal is to give birth to an HIV free generation. TASP can be improved, but must be complemented by aggressive prevention services. Pre Exposure Prevention is an important adjunct, as we just can't treat our way out of the epidemic. Integration of preventive services into HIV service models is essential as we expand the model of HIV care to a community oriented primary care model. Changes in educational models that stress engagement and empowerment on a community level are essential to bring parity to emerging communities at risk for HIV and other STDs. Harm reduction strategies that treat biological consequences of behavior can offer deeper reductions in HIV through prep and sterile injections.

The final mile in the delivery of optimal suppression is the hardest and involves social and health equalities. The differing models of the cascade illustrate the role of adequate insurance and social class. Both Washington DC as typified by a well functioning community health center that has nearly 100% coverage for health insurance and the Kaiser Permanente system have near universal coverage but suppression rates that vary greatly. Access can partially explain these differences, but class and poverty contribute to mental health and substance abuse, and may serve our toughest hurdle to cross.

129 Criminalizing HIV: Recent Experience in the United States and Africa to Update Laws and Policies to Promote the Public Health

Jeffrey Crowley

Georgetown University, Washington, DC, US

Laws and policies have been used to protect people living with HIV and affected communities from stigma and discrimination. Indeed, the Americans with Disabilities Act (ADA) and the UN Convention on the Rights of Persons with Disabilities are just two legal instruments that help to create environments where people feel safe enough to come forward for HIV testing and to engage in care. Laws and policies also are used in ways that are highly stigmatizing and that hinder public health approaches to responding to HIV. In the United States, thirty-four states and territories have laws that criminalize the conduct of people living with HIV based on perceived exposure to HIV and without any evidence of intent to do harm. Far from representing a legacy of the past, people with HIV continue to be prosecuted and jailed for failure to disclose their HIV status prior to engaging in sex and for spitting and biting offenses, often in the context of arrest by law enforcement. Moreover, this is a challenge in countries across the globe. As of 2013, twenty-six African countries had overly broad and/ or vague HIV-specific criminal laws, most enacted over the past decade, with a further three countries considering new HIV-specific criminal laws. As governments, clinicians, researchers, and advocates seek to maximize population-level HIV viral suppression both to protect the health of people with HIV and also to reduce HIV transmission, these laws and policies could hinder our collective efforts. This talk will examine the current landscape of HIV criminal laws and policies in the US and selected African countries, will examine available data on the effectiveness of such laws at deterring behaviors such as failure to disclose HIV status prior to sexual encounters, and will look for common lessons from both Africa and the US to suggest a path forward for promoting effective evidence-based approaches to reducing HIV transmission.

Session S-6 Symposium — Room 6E

Tuberculosis: Magic Bullets and Moving Targets

130 Advances in Mycobacterial Diagnostics

Mark P. Nicol

University of Cape Town, Cape Town, South Africa

The past 10 years have seen rapid advances in mycobacterial diagnostics. Specifically, nucleic acid amplification testing has been validated and widely implemented for both TB diagnosis and for identification of resistance to first and second line anti-TB drugs.

The World Health Organization has recommended use of Xpert MTB/RIF (Xpert) as the initial diagnostic test for TB in high HIV or drug-resistant TB settings, including testing of children and for specific forms of extra-pulmonary TB. Xpert simultaneously detects *M. tuberculosis* and identifies rifampicin resistance, has excellent specificity and improved sensitivity over smear microscopy for diagnosis of TB, but lacks sufficient sensitivity for use as a rule-out test for HIV-associated TB. Studies assessing the impact of Xpert implementation have shown mixed results, particularly where empiric treatment is common; as such treatment may reduce the impact of Xpert on case detection. The role of Xpert in reducing time to treatment, outcome and transmission of drug-resistant TB is an important area for further research.

Several other genotypic tests are now used for identification of resistance to first and second line anti-TB drugs. These detect the absence of wild-type (sensitive) sequence and/ or the presence of known resistance-conferring mutations. Line probe assays are commonly used, however targeted sequencing and whole genome sequencing are likely to be increasingly used as they provide improved specificity and broader mutation detection. Obstacles to the widespread implementation of sequencing include limited data on the genotype-phenotype relationship for many drugs, the lack of 'plug and play' pipelines for bioinformatics analysis and cost.

Gaps in the current portfolio of diagnostic tests include highly sensitive tests for the diagnosis of extra-pulmonary TB, TB in children and HIV-associated TB. There is a need for a true point-of-care diagnostic (or triage) test for use in remote, low-resource settings and for more simple and rapid tests for accurate detection of resistance to second-line anti-TB drugs.

131 New Medications, Innovative Approaches: Accelerate the TB Regimen Development Pipeline

Michael Hoelscher

University of Munich, Munich, Germany

This is an exciting time for tuberculosis drug development with a number of clinical trials reporting (REFAQUIN, OFLOTUB, REMoxTB). The challenge facing drug development is illustrated by the flouroquinolones trials to prove the promising results in Phase 2 regimens. It is time that we review drug development methodologies critically. The dizzying number of potential dosages and combinations of novel, established and repurposed agents requires rapid pre-selection of the most promising regimens from pre-clinical and early phase clinical trials. These regimens must be optimized at low cost to select the right regimen for a pivotal registration trial. A combination of innovative animal models, early clinical trial designs that gathers safety and DDI data as early as possible and efficacy outcome measurements in phase II studies that do not only look for bacillary clearance from sputum but also for relapse is needed. This presentation will review the different approaches that are currently under consideration.

132 Tuberculosis in Pregnancy

Amita Gupta

Johns Hopkins University School of Medicine, Baltimore, MD, US

Tuberculosis (TB) is a major cause of morbidity and mortality in women of childbearing age (15 to 44 years), accounting for almost 400,000 deaths in this age group every year. Pregnancy and HIV co-infection increase the likelihood that women with latent TB infection (LTBI) will progress to active TB disease, which raises the risk of poor maternal and infant outcomes. International guidelines

differ on the optimal regimen and dosing for TB treatment during pregnancy and postpartum in part because safety, tolerability, and pharmacokinetic (PK) data for many TB drugs are lacking in pregnant and postpartum women. This knowledge gap is of particular concern for women being treated for both TB and HIV infection and disease, who face overlapping drug toxicities and drug interactions between

TB and antiretroviral drugs. Promising new TB drugs have recently entered clinical development or have already been approved for use in non-pregnant adults, but currently there are no planned trials for any of these new agents in pregnant women. In this talk, I will highlight the management of TB during pregnancy including 1) the current knowledge and gaps regarding use of current and new antimycobacterial drugs during pregnancy as well as how pregnancy impacts the pharmacokinetics of anti-TB drugs and antiretroviral drugs; 2) how to manage antiretroviral therapy together with TB treatment during pregnancy; and 3) highlight new information about prevention of TB and unique aspects of treatment for latent TB infection that must be considered during pregnancy.

133 Tuberculosis in Children

Anneke C. Hesseling

Stellenbosch University, Cape Town, South Africa

This presentation will include an overview of the global epidemiology of tuberculosis in children, including the impact of HIV, and with specific emphasis on emerging data on drug-resistant TB.

Data will be presented on the historical challenges of evaluating existing and novel treatment strategies for TB in children. Emerging research opportunities and key early findings from pharmacokinetic studies and trials will be highlighted, addressing key pediatric populations including HIV-infected children, the treatment and prevention of MDR-TB, the use of novel drugs, and special treatment needs in infants and adolescents. An overview of research priories and planned and ongoing trials will be presented, and a framework to the evaluation of new TB drugs and regimens discussed.

Diagnostic challenges and new approaches to the diagnosis of TB, including novel biomarkers, molecular approaches and novel sampling strategies will be reviewed and global collaborative research efforts highlighted.

Cardiovascular Disease in HIV Patients: An Emerging Paradigm and Call to Action

134 Cardiovascular Disease in HIV Patients: An Emerging Paradigm and Call to Action

Steven Grinspoon

Massachusetts General Hospital, Harvard Medical School, Boston, MA, US

Cardiovascular disease (CVD) has emerged as an important co-morbidity in HIV-infected patients. The relative risk of CVD, including myocardial infarction and stroke, is increased in HIV patients compared to age and gender-matched non HIV patients. Although some traditional risks, including smoking, are increased in HIV-infected patients and should be targeted for treatment, very often this disease occurs in relatively young, asymptomatic patients with only modest increases in traditional risk scores. Epidemiological studies suggest unique patterns of CVD in HIV patients, for example younger HIV-infected women may be less protected from CVD than younger women in the general population. Recent studies suggest an emerging mechanistic paradigm in which persistent immune activation and inflammation may contribute to atherosclerotic disease in HIV patients. In the HIV population, this disease manifests itself as subclinical, primarily non-calcified, vulnerable plaque, at increased risk for rupture. Indeed studies show increased rates of sudden cardiac death in the HIV population, consistent with acute rupture of vulnerable plaque. Monocyte activation and trafficking into the arterial surface may contribute to an inflammatory pro-thrombotic local milieu, more amenable to buildup of plaques with lipid laden foam cells and a thin necrotic surface. Indeed, molecular imaging techniques, assessing metabolic indices, suggest increased activity at the arterial surface among HIV patients, in association with immune activation and high risk, low attenuation, positively remodeled plaque. Treatment options to prevent CVD in HIV patients are critically needed. Emerging data suggests that targeting inflammation and immune activation may be useful to reduce CVD risk in the HIV population and specific strategies targeting these pathways are now under investigation. Significant evidence suggests that statins may offer

a number of benefits, potentially useful to lower CVD risk and prevent disease in the HIV population. Statins have been shown to reduce arterial inflammation, reduce monocyte activation and trafficking, and target key systemic inflammatory pathways. In addition, this class of agents reliably lowers LDL and thus may have advantages in reducing both traditional and nontraditional risk factors. Large scale NIH funded studies are now underway to test whether statins can safely prevent CVD in HV and the mechanisms by which this effect may occur.

Session PL-2 Plenary **4AB Auditorium**

9:00 am – 9:30 am

The Price of Selling Sex: HIV Among Female Sex Workers—The Context and the Public Health Response

135 The Price of Selling Sex: HIV Among Female Sex Workers—The Context and the Public Health Response

Frances M. Cowan

University College London, London, United Kingdom

Background: HIV prevalence among female sex workers (FSW) remains disproportionately high, on average 13 times higher than among the general population in low and middle income countries. FSW in sub-Saharan Africa are most severely affected. Effective HIV prevention interventions among FSWs include condom promotion, STI management, HIV testing and counselling, gender-based violence prevention, and community organising, but have not been taken to scale in many parts of the world. Structural and social factors further limit uptake of HIV prevention and care services. Mathematical modelling indicates that newer biomedical prevention technologies such as pre-exposure prophylaxis (PrEP) and treatment as prevention (TasP) may provide additional prevention benefits over and above existing interventions, if mechanisms to support uptake, delivery and adherence can be developed and successfully implemented. Additionally, modelling suggests that PrEP is likely to be most cost-effective if used among those at highest risk of infection. Participation by FSW in the design and implementation of programs to ensure that they address local social and structural barriers to their health and rights has been shown to enhance program effectiveness. Modelling the impact of structural interventions suggests that decriminalisation of sex work would provide the greatest prevention gain across a range of settings through its combined effects on violence, police harassment, safer work environments, and HIV transmission pathways. Interventions to increase access to and retention in treatment and care services among FSW also need to be optimised, evaluated and taken to scale in a way that meets their needs. Achieving UNAIDS goal of 90:90:90 will not occur without sex worker led interventions that actively seek to address the social and structural barriers that FSW face when accessing HIV prevention and care services.

Conclusions: The presentation will i) describe the epidemiology of HIV among FSWs including the extent of, and the barriers to, their engagement in prevention and care, ii) present research on effective prevention interventions and the novel combination prevention and care approaches that are currently under evaluation iii) review recent modeling studies to look at the potential additive impact of adding these novel approaches.

Session O-11 Oral Abstracts **Room 6C**

10:00 am – 12:15 pm

Cardiovascular, Bone, and Kidney Health

136 Statin Therapy Reduces Coronary Noncalcified Plaque Volume in HIV Patients: A Randomized Controlled Trial

Janet Lo[1]; Michael Lu[2]; Ezinne Ihenachor[1]; Jeffrey Wei[1]; Sara Looby[1]; Kathleen Fitch[1]; Suhny Abbara[2]; Gregory Robbins[1]; Udo Hoffmann[2]; Steven Grinspoon[1]

[1]*Massachusetts General Hospital, Harvard Medical School, Boston, MA, US;* [2]*Massachusetts General Hospital, Boston, MA, US*

Background: Statins reduce cardiovascular events and deter progression of atherosclerosis. No studies have yet assessed the ability of statin treatment to achieve regression of coronary atherosclerosis in HIV-infected patients, a population demonstrated to have elevated risk of myocardial infarction.

Methods: In a randomized, double-blind, placebo-controlled trial, 40 HIV-infected participants with subclinical coronary atherosclerosis and low density lipoprotein (LDL)-cholesterol < 130mg/dL were randomized to one year of treatment with atorvastatin or placebo to determine the effect on coronary atherosclerotic plaque as assessed by coronary computed tomography angiography. We quantitatively assessed non-calcified plaque and high risk plaque features (low attenuation, spotty calcification, and positive remodeling index).

Results: After 12 months, atorvastatin reduced noncalcified coronary plaque volume compared to placebo (-19.4% [-39.2%, 9.3%] vs. +20.4% [-7.1%, 94.4%], p=0.009). In addition, the number of high risk plaques was significantly reduced by atorvastatin compared to placebo (change in number of low attenuation plaques -0.2 ± 0.8 vs. 0.4 ± 0.7 lesions, p=0.03 and change in number of positively remodeled plaques -0.2 ± 0.5 vs. 0.4 ± 0.9, p=0.04). Direct LDL-cholesterol (-38 ± 29 vs. 11 ± 21 mg/dL, p<0.0001) and lipoprotein-associated phospholipase A_2 (-52.2 ± 36.6 vs. -13.3 ± 42.8 ng/dL, p=0.005) significantly decreased with atorvastatin compared to placebo. Statin therapy was well-tolerated, with low incidence of clinical adverse events or laboratory abnormalities.

Conclusions: As compared to placebo**,** statin therapy reduces noncalcified plaque volume and high risk plaque features in HIV-infected patients with subclinical coronary atherosclerosis. Further studies should assess whether reduction in high risk coronary artery disease may translate into effective prevention of cardiovascular events in this at risk population of HIV patients.

137 Rosuvastatin Arrests Progression of Carotid Intima-Media Thickness in Treated HIV

Chris T. Longenecker[1]; Ying Jiang[1]; Sara M. Debanne[1]; Danielle Labbato[2]; Bruce Kinley[2]; Norma Storer[2]; **Grace A. McComsey**[1]

[1]*Case Western Reserve University, Cleveland, OH, US;* [2]*University Hospitals of Cleveland, Cleveland, OH, US*

Background: Statins slow progression of carotid intima-media thickness (IMT) and prevent cardiovascular events in HIV uninfected subjects. To what degree they may slow progression of carotid disease in HIV-infected patients on antiretroviral therapy (ART) is unknown.

Methods: SATURN-HIV was a 96-week double-blind, randomized clinical trial of 10 mg daily rosuvastatin versus placebo among 147 HIV-infected subjects on stable ART with LDL-cholesterol ≤130mg/dL and evidence of heightened T-cell activation (CD8+CD38+HLA-DR+ ≥19%) or increased inflammation (high sensitivity C-reactive protein ≥2mg/L). Randomization was stratified by protease inhibitor use and coronary artery calcium (CAC) score. Common carotid artery IMT (CCA-IMT) and presence of carotid plaque were assessed by ultrasound using semi-automated edge detection software. CAC was measured by gated cardiac CT. The study was designed to have >80% power to detect a 0.118 mm difference in the primary outcome of mean-mean CCA-IMT change. All analyses were intent to treat.

Results: Median (Q1, Q3) age was 46 (40, 53) years; 78% were male and 68% African American; 49% were on a protease inhibitor. Baseline median CCA-IMT was similar between groups [0.664 (0.624, 0.772) vs. 0.670 (0.602, 0.752) mm, statin vs. placebo, p=0.50]. At baseline, at least a third had carotid plaque (33% vs. 43%, statin vs. placebo, p=0.24) or detectable CAC (33% vs. 40%, statin vs. placebo, p=0.40). Overall, CCA-IMT progression was slower than anticipated [mean (standard deviation) 96 week change +0.015 (0.071) mm]. Within the placebo group, mean CCA-IMT progressed significantly over 96 weeks, but was unchanged in the statin group (see Figure). Mean difference in annualized rate of CCA-IMT

change between groups was 0.014 mm/yr. Among those without carotid plaque at baseline, there was no difference in development of new plaque by week 96 (4.9% vs. 6.5%, statin vs. placebo, p=0.82). Among those without CAC at baseline, there was a trend towards more detectable CAC after 96 weeks of statin (15% vs. 6%, statin vs. placebo, p=0.19).

	Mean 96 week change	95% Confidence Interval	Within group p-value	Between group p-value
Placebo	+0.028 mm	0.008 – 0.047	0.006	0.074
Rosuvastatin	+0.003mm	-0.014 – 0.021	0.714	

Change in mean-mean common carotid artery intima-media thickness (CCA-IMT) over 96 weeks according to study group assignment.

Conclusions: Rosuvastatin 10 mg daily appears to halt progression of carotid IMT in HIV-infected patients on ART with low LDL-cholesterol and high levels of immune activation. The effect on IMT progression is similar in magnitude to studies of HIV-uninfected populations and provides further justification for clinical outcomes trials in this population.

138 Calcified Plaque Burden Is Associated With Serum Gut Microbiota-Generated TMA in HIV

Suman Srinivasa[1]; Kathleen V. Fitch[1]; Janet Lo[1]; Hanane Kadar[2]; Kimberly Wong[1]; Suhny Abbara[3]; Dominique Gauguier[2]; Jacqueline Capeau[2]; Franck Boccara[2]; Steven K. Grinspoon[1]
[1]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [2]University Pierre & Marie Curie, Paris, France; [3]University of Texas Southwestern Medical Center, Dallas, TX, US

Background: Some gut microbiota-generated metabolites of phosphatidylcholine are recognized to be pro-atherogenic. The HIV population is more vulnerable to cardiovascular disease (CVD) than the general population and can develop impaired intestinal wall integrity and dysbiosis associated with inflammation. We investigated the novel relationship between microbiota-derived choline-related metabolites and coronary atherosclerosis in HIV.

Methods: 155 HIV-infected and 67 non-HIV-infected subjects without known CVD were previously recruited in a prospective study to assess coronary plaque by cardiac CT angiography. In the current study, we evaluated serum choline, trimethylamine (TMA) and trimethylamine N-oxide (TMAO) in association with plaque features and systemic inflammatory markers. A mass spectrometry-based method was designed to assay choline-related metabolites from serum. Linear regression was performed by Pearson's correlation after non-normally distributed variables were log transformed.

Results: Young, asymptomatic HIV-infected subjects(mean age 47±7 yrs, duration HIV 14±6 yrs, duration ART 8±5 yrs, CD4$^+$ count 552± 290 cells/μl, undetectable VL 86%) demonstrated significantly higher prevalence of plaque(53 vs. 35%, P=0.01) and total plaque segments(1.8±2.5 vs. 1.2±2.2, P=0.03) when compared to well-matched non-infected subjects with similar co-morbidities. TMA was significantly associated with number of total(r=0.20, P=0.02) and calcified(r=0.18, P=0.03) plaque segments; calcium score(r=0.22, P=0.006); calcium plaque volume (r=0.19, P=0.02) and mass(r=0.22, P=0.009); and lipopolysaccharides (LPS) (r=0.19, P=0.03) in the HIV cohort only. In multivariate modeling among HIV-infected subjects, TMA remained significantly associated with number of total(P=0.005) and calcified(P=0.02) plaque segments; calcium score(P=0.008); and calcium plaque volume(P=0.01) and mass(P=0.007), independent of Framingham Risk Score (FRS). Furthermore, TMA was still an independent predictor of total plaque segments(P=0.03), calcium score(P=0.04), and calcium plaque mass(P=0.03), after controlling for FRS and LPS. In contrast, there was no association of TMAO to plaque features in either cohort.

Conclusions: TMA, a microbiota-derived precursor of TMAO, may be a non-traditional cardiovascular risk factor which has independent effects on the number of coronary plaque segments and severity of calcified plaque burden in HIV. This relationship may derive from altered gut flora or microbial translocation unique to HIV.

139 Varenicline vs Placebo for Smoking Cessation: ANRS 144 Inter-ACTIV Randomized Trial

Patrick Mercie[3]; Caroline Roussillon[1]; Christine Katlama[4]; Aurélie Beuscart[1]; Samuel Ferret[2]; Nathalie Wirth[5]; David Zucman[6]; Xavier Duval[7]; Genevieve Chene[1]
ANRS 144 inter-ACTIV study group
[1]Inserm U897, Bordeaux, France; [2]Hosp. Saint-Louis, Paris, France; [3]Hosp. Saint-André, Bordeaux, France; [4]Hosp. La Pitié-Salpêtrière, Paris, France; [5]Hosp. De Brabois, Vandoeuvre les Nancy, France; [6]Hosp. Foch, Suresnes, France; [7]CIC 1425, Paris, France

Background: About half of HIV-infected patients are regular tobacco smokers in Europe, a higher prevalence than the general population. Tobacco is an important determinant of non AIDS morbidity and mortality (including vascular diseases and malignancies), a major reason to promote tobacco cessation. It is unclear whether varenicline is safe and efficacious for smoking cessation in HIV-infected patients. We evaluated varenicline at 48 weeks in regular smokers motivated to quit smoking.

Methods: Randomized (1:1), placebo-controlled clinical trial with a 12-week treatment period (from 0.5 mg once daily to 1 mg twice daily at the end of the first week) and a further 36-week follow-up, including smoking cessation counseling in both arms, conducted in 30 ANRS centers from Oct. 2009 to Jan. 2014. Self-reported tobacco abstinence was confirmed by exhaled carbon monoxide measurements at 9 weeks and at intervals up to 48 weeks. The primary endpoint was continuous abstinence rate from week 9 to 48. Secondary endpoints included continuous abstinence rate from week 9 to 12 and adverse events.

Results: 248 smokers were randomized; 213 included in the modified intention-to-treat analysis (102 varenicline, 111 placebo), others did not start trial treatment. Median age was 45 years, 83% male, median nadir CD4+ 213/mm^3, baseline CD4+ 617/mm^3 and undetectable HIV RNA 73%. Varenicline was associated with a higher continuous abstinence rate at 48 weeks than placebo: 17.6% *vs* 7.2% (*p=0.02)* and 34.3% *vs* 12.6% at 12 weeks (*p=0.0002)*. At 48 weeks, median CD4+ was 615/mm^3 and 80% had undetectable HIV RNA, without difference between arms. Grade 3/4 drug-related effects were reported in 7 patients in each arm, including 9 psychiatric side effects (5 in the varenicline arm *vs* 4 in

the placebo arm) and 3 gastrointestinal side effects (1 and 2, respectively). At least one depressive episode related to trial treatment was reported in 1 and 7 patients, respectively. Among 7 grade 3/4 cardiovascular events, 4 occurred in the varenicline arm (not treatment related) and 3 in the placebo arm. No neurovascular event was reported.

Conclusions: Varenicline is safe and effective in HIV infected patients with a 34% rate of tobacco abstinence at 12 weeks (end of treatment) and 18% at 48 weeks. These results are in the range of those reported in the HIV uninfected population. Varenicline should be considered as part of the standard of care in HIV-infected patients motivated to quit smoking.

140 Body Composition Changes After Initiation of Raltegravir or Protease Inhibitors

Grace A. McComsey[1]; Carlee Moser[2]; Judith S. Currier[8]; Heather Ribaudo[2]; Pawel Paczuski[2]; Michael P. Dube[5]; Robert L. Murphy[6]; Jennifer Rothenberg[7]; James H. Stein[4]; Todd T. Brown[3]

[1]Case Western Reserve University, Cleveland, OH, US; [2]Harvard School of Public Health, Center for Biostatistics in AIDS Research, Boston, MA, US; [3]Johns Hopkins University School of Medicine, Baltimore, MD, US; [4]University of Wisconsin School of Medicine and Public Health, Madison, WI, US; [5]University of Southern California, Los Angeles, CA, US; [6]Northwestern University, Chicago, IL, US; [7]Social & Scientific Systems, Inc., Silver Spring, MD, US; [8]University of California Los Angeles, Los Angeles, CA, US

Background: Although lipoatrophy is uncommon with current antiretroviral therapy (ART), fat accumulation continues to occur, and its association with protease inhibitors (PIs) has been questioned. The effect of integrase inhibitors vs. PIs on body composition has not been established.

Methods: We compared the percentage change in lean mass (by DXA), peripheral fat (limb fat by DXA and subcutaneous abdominal fat (SAT) by CT scan of abdomen), and central fat (trunk fat by DXA and visceral abdominal fat (VAT) by CT) over 96 weeks in HIV-infected treatment-naive participants randomized to open labeled tenofovir disoproxil fumarate-emtricitabine (TDF/FTC) plus atazanavir-ritonavir (ATV/r), darunavir-ritonavir (DRV/r), or raltegravir (RAL) in ACTG 5260s, a substudy of A5257. DXA and CT measurements were standardized and centrally read. Linear regression, adjusting for the stratification factors of baseline cardiometabolic risk and HIV-1 RNA, was used to compare the 96-week percentage change in fat and lean mass in the two PI arms (ATV/r vs DRV/r) and, if not different, the PI arms were combined and compared to RAL arm. Associations between baseline biomarkers and changes in body composition were assessed with linear regression models adjusting for baseline age, BMI, HIV-RNA, CD4 count, sex and race/ethnicity. Within arm changes were assessed with signed-rank tests. All analyses were intent-to-treat.

Results: 328 participants were randomized; 90% were male and 44% white, non-Hispanic; median age was 36 years, HIV-1 RNA load 4.55 log10 copies/mL, and CD4 count 349 cells/μL. At week 96, the median percentage increases in limb fat, SAT, VAT, trunk fat, and lean mass were statistically significant in all arms (8.2%, 10.9%, 13.9%, 11.4%, 1.3%; $p<0.001$). Changes for all fat outcomes were not different between the PI arms ($p\geq0.36$), however greater gains in lean mass with ATV/r vs. DRV/r were detected (3.8% vs. 2.3%; $p=0.05$). There were no significant differences between the RAL arm and combined PI arm in any fat or lean mass endpoints ($p\geq0.36$). While lower baseline leptin and higher RNA levels were associated with greater gains in peripheral and central fat, higher baseline IL-6 was only associated with greater gains in peripheral fat.

Conclusions: In ART-naïve subjects initiating ART with TDF/FTC, RAL led to similar increases in lean mass, and central and peripheral fat as compared to ATV/r and DRV/r. We saw no evidence to suggest that the PIs were associated with greater increases in central fat than RAL

141 Fracture Prediction With Modified FRAX in Older HIV+ and HIV- Men

Michael T. Yin[1]; Melissa Skanderson[7]; Stephanie Shiau[1]; Katherine Harwood[1]; Josh Aschheim[3]; David Rimland[2]; Cynthia Gibert[5]; Maria Rodriguez-Barradas[4]; Roger Bedimo[6]; Julie Womack[7]

[1]Columbia University Medical Center, New York, NY, US; [2]VAMC and Emory School of Medicine, Atlanta, GA, US; [3]Arcadia Healthcare Solutions, New York, NY, US; [4]Baylor College of Medicine, Houston, TX, US; [5]VA Medical Center, George Washington University, Washington, DC, US; [6]University of Texas, Dallas, TX, US; [7]VA Connecticut Healthcare System, West Haven, CT, US

Background: Fracture rates are increased in HIV+ individuals. FRAX is a web-based fracture risk calculator used with or without bone mineral density (BMD) that estimates absolute 10-year risk of major osteoporotic (hip, spine, forearm, shoulder) and hip fracture. It is widely used for decision making in screening and treatment for fracture prevention. Since FRAX may underestimate fracture risk in HIV+ individuals; some experts recommend adding 'secondary osteoporosis' as a surrogate for HIV infection when using FRAX in an HIV+ patient.

Methods: From the Veterans Aging Study Virtual Cohort (VACS-VC), 26,037 HIV+/HIV- 50-70 year-old men were selected for whom complete data were available in 2000 to approximate all but 2 factors for FRAX calculation without BMD (history of secondary osteoporosis and parental hip fracture). Sum of estimated rates by this modified FRAX calculation was compared to observed 10-year fracture rates at similar body sites. Calibration (agreement between observed outcomes and predictions) by observed to estimated ratios (O/E) and discrimination (ability to discriminate subjects with and without outcome) by area under the curve (AUC) were compared by HIV status

Results: In 2000, HIV+ men were similar in age (56±5 vs 56±5, $p=0.11$) to HIV- men, but had lower weight (79±15 vs 89±16 kg, $p<0.01$), were more likely to report previous fracture, alcohol and glucocorticoid use, and less likely to smoke or have rheumatoid arthritis. More fractures occurred in HIV+ than HIV- men at major osteoporosis sites (4.61 vs 3.50%, $p<0.01$) and hip (1.32 vs 0.85%, $p<0.01$). Estimated rates by the modified FRAX were also higher for HIV+ than HIV- men at major osteoporosis sites (2.85 ±1.5 vs 2.71±1.4%, $p<0.01$) and hip (0.29 ±0.4 vs 0.24±0.3%, $p<0.01$). Calibration for major osteoporotic fracture was worse in HIV+ than HIV- men (1.62 vs 1.29, $p=0.028$). Discrimination for modified FRAX was poor, but did not differ by HIV status (Table). Adding 'secondary osteoporosis' as a surrogate for HIV-infection risk in FRAX calculation improved calibration to level of HIV- men (O/E=1.20), but did not improve discrimination (AUC=0.600).

		Major osteoporitic fractures		Calibration		Discrimination	
	N	Observed	Expected	O/E	95% CI	AUC	95% CI
All	24451	935	673	1.39	1.30, 1.48	0.58	0.57, 0.60
HIV+	7064	326	201	1.62	1.45, 1.81	0.60	0.57, 0.63
HIV-	17387	609	471	1.29	1.19, 1.40	0.57	0.55, 0.60

Conclusions: In this study of older men, the modified FRAX score underestimates fracture rates more in HIV+ than HIV- men, and does not discriminate well between those at risk and not at risk for future fracture. Including 'secondary osteoporosis' as a surrogate risk factor may improve the performance of the modified FRAX in HIV+ patients.

142 Exposure to Antiretrovirals (ARVs) and Development of Chronic Kidney Disease (CKD)

Amanda Mocroft[1]; Jens D. Lundgren[2]; Michael Ross[3]; Christoph Fux[4]; Peter Reiss[5]; Olivier Moranne[6]; Philippe Morlat[7]; Antonella d'Arminio Monforte[8]; Ole Kirk[2]; Lene Ryom[2]
On behalf of the The Data Collection on Adverse Events of Anti-HIV Drugs (D:A:D) Study Group

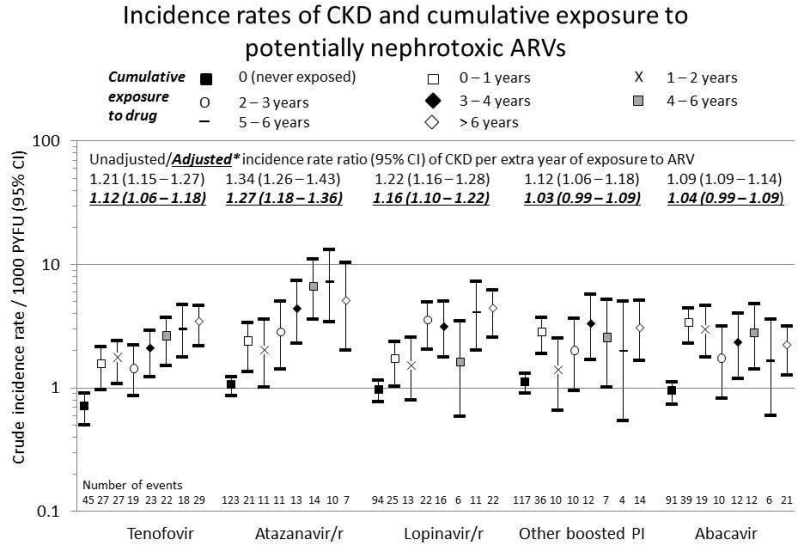
[1]University College London, London, United Kingdom; [2]Copenhagen HIV Programme, Centre for Health and Infectious Diseases Network, University of Copenhagen, Denmark, Denmark; [3]Division of Nephrology, Mount Sinai School of Medicine, New York, NY, US; [4]Clinic for Infectious Diseases and Hospital Hygiene, Kantonsspital Aarau, Aarau, Switzerland; [5]Academic Medical Center, Div. of Infectious Diseases and Dept. of Global Health, University of Amsterdam, Amsterdam, Netherlands; [6]Université de Bordeaux, Inserm U 897, Bordeaux, France; [7]Public Health Department, Nice, France; [8]Istituto Di Clinica Malattie Infettive e Tropicale, Milan, Italy

Background: Previous studies in persons with an initially normal eGFR have been underpowered to assess whether the incidence of CKD increases immediately after starting potentially nephrotoxic ARVs and then remains stable or continues to increase with duration of exposure.

Methods: D:A:D study participants were followed from baseline until earliest of CKD, last eGFR, 1/1/2013 or last visit plus 6 months. Baseline was defined as the first eGFR after 1/1/2004; persons with <2 eGFRs after baseline or where baseline eGFR <90 ml/min/1.73m^2 were excluded. CKD was defined as confirmed (>3 months apart) eGFR <60 ml/min/1.73m^2

and chronic renal impairment (CRI) as confirmed (>3 months apart) eGFR <70 ml/min/1.73m^2. Poisson regression was used to estimate the incidence of CKD associated with cumulative exposure to or time since stopping tenofovir (TDF),ritonavir-boosted atazanavir (ATV/r), lopinavir (LPV/r), other ritonavir-boosted protease inhibitors (BPI) or abacavir (ABC).

Results: 23560 persons were included with median baseline eGFR 110ml/min/1.73m^2 (IQR 100–125), age 39 years (IQR 33–45) and CD4 440/mm^3 (IQR 293–629). During a median follow-up of 6.3 years (IQR 4.4–8.0), 210 persons developed CKD (0.9%; incidence 1.48/1000 PYFU; 95% CI 1.28–1.68). The crude incidence of CKD increased as exposure to TDF, LPV/r and ATV/r increased, but not as clearly for BPI and ABC (Figure). After adjustment, there was a significant increase in CKD associated with increasing exposure to TDF, ATV/r and LPV/r (all p<0.0001) but not other BPI (p=0.44) or ABC (p=0.12; Figure). Results were consistent for CRI and when limited to those currently on ARVs. There was a decrease in the incidence of CKD as time since stopping TDF increased, with no clear picture for the other ARVs. Those who had stopped TDF for >2 years had a significantly raised incidence of CKD (adjusted incidence rate ratio 2.47; 95% CI 1.36–4.48) compared to those never exposed to TDF.



Multivariate models adjusted for race, HIV exposure risk, D:A:D cohort, study, gender, nadir CD4, baseline date and eGFR, and hepatitis B*, hepatitis C*, smoking status*, BMI*, family history of CVD*, viral load*, CD4*, a new AIDS diagnosis within the past 12 months* (time updated variables*). Models were additionally adjusted for cumulative exposure to indinavir.

Conclusions: The association between TDF, ATV/r, LPV/r and CKD in persons with an initially normal eGFR was not limited to an increased incidence immediately after starting the ARV, but clearly persisted with increasing exposure to TDF, LPV/r and ATV/r. After 6 years exposure, the relative risk of CKD was increased by 97%, 320% and 140% for TDF, ATV/r and LPV/r respectively. A clear decrease in the incidence of CKD after stopping ARVs was only observed for TDF; but the incidence remained significantly higher 2 years after stopping compared to those who had never started TDF.

143LB Renal and Bone Safety of Tenofovir Alafenamide vs Tenofovir Disoproxil Fumarate

Paul E. Sax[7]; Michael S. Saag[2]; Michael T. Yin[3]; Frank A. Post[4]; Shinichi Oka[8]; Ellen Koenig[5]; Benoit Trottier[9]; Jaime Andrade-Villanueva[6]; Huyen Cao[1]; Marshall W. Fordyce[1]

[1]Gilead Sciences Inc, Foster City, CA, US; [2]University of Alabama at Birmingham, Birmingham, AL, US; [3]College of Physicians and Surgeons, Columbia University, New York, NY, US; [4]King's College Hospital, London, United Kingdom; [5]Dominican Institute for Virologic Studies, Santo Domingo, Dominican Republic; [6]Unidad de VIH del Hospital Civil de Guadalajara, Guadalajara, Mexico; [7]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, US; [8]National Center for Global Health and Medicine, Japan, Tokyo, Japan; [9]Clinique Medicale l'Actuel, Montreal, Canada

Background: Off-target renal and bone side effects may occur with tenofovir disoproxil fumarate (TDF) use. Compared with TDF, tenofovir alafenamide (TAF) results in significantly reduced plasma tenofovir (TFV) and may have less renal and bone toxicity.

Methods: Treatment naïve HIV-1$^+$ adults were randomized 1:1 to a single tablet regimen of E/C/F/TAF or E/C/F/TDF once daily in two double blind studies. Assessments included measures of renal function and bone mineral density (BMD). Four pre-specified secondary safety endpoints were tested: serum creatinine, treatment-emergent proteinuria, spine and hip BMD. Week 48 off-target side effects data are described.

Results: Combined, the two studies randomized and treated 1,733 subjects. Plasma TFV was >90% lower (mean [%CV] AUC_{tau} 297 (20) vs. 3,410 (25) nghr/mL) in the E/C/F/TAF arm, compared to the E/C/F/TDF arm. Serum creatinine (mean [SD] change: +0.08 [0.124] vs +0.11 [0.217] mg/dL, p<0.001), quantified proteinuria (UPCR, median [Q1, Q3] % change; -3 [-35, +43] vs +20 [-23, +76], p<0.001), albuminuria (UACR, median [Q1, Q3] % change; -5 [-33, +36] vs +7 [-27, +62], p=0.001), retinol binding protein (RBP:Cr, median [Q1, Q3] % change; +9 [-23, +49] vs +51 [+3, +133]), beta-2-microglobulin (β-2-Mg:Cr, median [Q1, Q3] % change; -32 [-57, +4] vs +24 [-34, +168]), and fractional excretion of phosphate (median [Q1, Q3] % change; +0.9 [-2.0, +4.5] vs +1.7 [-1.6, +5.3]), all favored E/C/F/TAF. There were no cases of proximal tubulopathy in either arm. Mean (SD) % decrease in BMD was significantly less in the E/C/F/TAF arm for both lumbar spine (-1.30 [3.08] vs -2.86 [3.25], p<0.001) and total hip (-0.66 [3.26] vs -2.95 [3.41], p<0.001). Increases from baseline in bone turnover biomarkers (C-telopeptide and P1NP) and parathyroid hormone were significantly smaller in the E/C/F/TAF group compared with the E/C/F/TDF arm (p < 0.001 for all). Increases in fasting lipid parameters (total cholesterol, HDL, direct LDL, and triglycerides) were greater in the E/C/F/TAF arm (p < 0.001 for all).

Conclusions: Through 48 weeks, subjects receiving E/C/F/TAF had significantly better outcomes related to renal and bone health than those treated with E/C/F/TDF; lipid outcomes favored E/C/F/TDF. Collectively these data demonstrate important safety benefits of TAF relative to TDF, especially given the aging of the HIV population and the need for long-term treatment.

144 Special Presentation: Update on National Heart, Lung, and Blood Institute High-Impact AIDS Research

Curing HCV: Mission Accomplished

145 The Burden of Liver Disease Among Persons With Hepatitis C in the United States

Monina Klevens[1]; Xiaohua Huang[2]; Anthony E. Yeo[2]; Mouneer Odeh[2]; Rick L. Pesano[2]; John W. Ward[1]

[1]US Centers for Disease Control and Prevention, Atlanta, GA, US; [2]Quest Diagnostics, Madison, NJ, US

Background: In the United States, the CDC recommends one-time hepatitis C virus (HCV) antibody testing for persons born from 1945-1965 due to the higher seroprevalence of HCV infection in this group. However, the burden of liver disease among the infected population has not been described.

Methods: Data were from Quest Diagnostics, a CDC partner, which conducts routine HCV tests in all states. For this analysis, all test data were anonymized and de-duplicated at the person level. The sample included all tests for which a first positive HCV RNA result was known for a given year from 2010-2013. Values for AST, platelet count and ALT, were combined with age to calculate FIB-4, a non-invasive scoring system indicative of liver fibrosis. Test data were then examined by year and stage of fibrosis.

Results: During 2010-2013, a total of 273,143 persons had a first positive HCV-RNA test result and known date of birth. Of these, 186,416 (68.2%) were born from 1945-1965. For all years combined, most persons in the birth cohort had moderate fibrosis (42.3%) followed by severe fibrosis (28.7%) and cirrhosis (22.7%). Almost no variation was found over the four-year period by stage of FIB-4 (Table). In 2013, 53.1% of persons born from 1945-1965 had severe fibrosis or cirrhosis; this was higher than among persons born after 1965 (12.4%) but lower than among persons born before 1945 (79.7%).

Number and percent+ of persons born during 1945-1965 with a first positive HCV-RNA test result* by year and stage of fibrosis

Category of fibrosis (mean FIB-4)	2010	2011	2012	2013
No fibrosis (<1.0)	2712 (10%)	2366 (10%)	1625 (9%)	1209 (9%)
Moderate fibrosis (1.0-2.0)	11195 (41%)	10369 (42%)	7460 (40%)	5566 (40%)
Severe (2.0-3.7)	7378 (27%)	6750 (27%)	5310 (28%)	3982 (28%)
Cirrhosis (≥3.8)	5908 (22%)	5140 (21%)	4266 (23%)	3220 (23%)
Total including missing/unknown^	38471	35458	27315	20687

+ Percentage excluding unknown/missing

*Not known to have a previous positive RNA test

^ Includes persons with ≥1 parameter missing

Conclusions: Alarmingly, about one-half of HCV-infected persons born from 1945-1965 had severe fibrosis or cirrhosis as evidenced by FIB-4 scoring. No decreases were observed in this proportion over time. Persons with this stage of severe HCV-related liver disease are a high priority for treatment. Improved birth cohort screening for HCV and linkage to recommended care and treatment are urgently needed to prevent complications.

146 High Efficacy of Daclatasvir/Asunaprevir/PR in HIV/HCV1-4 Null Responders (ANRS HC30)

Lionel Piroth[1]; Hubert Paniez[2]; Corine Vincent[2]; Karine Lacombe[3]; David Rey[4]; Didier Neau[5]; Jacques Izopet[6]; Alpha Diallo[7]; Laurence Meyer[2]; Jean-Michel Molina[8]

[1]CHU Dijon, Dijon, France; [2]Inserm, Paris, France; [3]Hôpital Saint-Antoine, Paris, France; [4]Strasbourg University Hospital, Strasbourg, France; [5]CHU, Bordeaux, France; [6]CHU, Toulouse, France; [7]Inserm-ANRS, Paris, France; [8]CHU Saint Louis, Paris, France

Background: Few direct anti-HCV agents (DAAs) have been studied in difficult to treat HIV co-infected patients, in particular null responder and cirrhotic. Daclatasvir and Asunaprevir combined with pegylated interferon-ribavirin (PR) have shown promising results in HCV mono-infected patients.

Methods: An open label, single arm, phase 2 study (ANRS HC30 QUADRIH) in HIV/HCV genotype (GT) 1 or 4 co-infected patients, null responders to prior pegylated interferon-ribavirin (PR) standard bitherapy. Patients had to have plasma HIV RNA levels < 400 cp/ml and received a 4-week lead-in phase with PR, followed by 24 weeks of asunaprevir (100mg bid), daclatasvir (60 mg qd), and PR. The primary endpoint was sustained virological response 12 weeks after the end of treatment (SVR12) using ITT analysis.

Results: Seventy-five patients (59 men/16 women) were included, median age 50 (IQR: 48 - 53) years, 27 (36%) cirrhotic. All were on a raltegravir-based regimen, 92% with baseline (BL) plasma HIV RNA level <50cp/ml, with BL median CD4 count 748 (481 - 930)/mm^3. BL plasma HCV viral load was 6.1 (5.8 - 6.6) log10 UI/mL.

The global SVR12 rate was 96.0% (72/75; 95%CI: 91.6%-100%). SVR12 was 92.6% (25/27; 82.7%-100%) in cirrhotic patients, 94.6% (35/37; 87.3%-100%) in GT1and 97.4% (37/38; 92.3%-100%) in GT 4. Eleven patients (15%) reached HCV undetectability at W5, 28 (37%) at W6, and 45 (60%) at W8. In the 51 patients experiencing less than a 1 $\log_{10}$ IU/ml HCV RNA decrease during the lead-in phase, SVR12 was 94.1%.

Six patients (8%) prematurely stopped HCV therapy, 2 due to virological breakthrough, and 4 to adverse events (one lung cancer, 3 infections). One of these patients (with BL platelets<150,000/mm^3 and BL albumin<35g/l) died from multivisceral failure. Overall, 35 serious adverse events occurred in 21 (28%) patients (9 cirrhotic and 12 non cirrhotic, p=0. 44), including hematological (15%, mainly anemia and neutropenia), gastrointestinal (5%), psychiatric events (5%, mainly insomnia), and infections (5%).

Conclusions: In HIV/HCV GT1/4 null responders, one third of whom had cirrhosis, a 24-week regimen combining daclatasvir/asunaprevir/PR was associated with a very high SVR12 rate. The safety profile was acceptable, even though cirrhotic patients with low albumin and platelets levels should be closely monitored This combination represents a new treatment option in this highly difficult to treat population.

147 High SVR Regardless of Time to Suppression With ABT-450/r/Ombitasvir & Dasabuvir+RBV

David Wyles[1]; Joseph J. Eron[2]; Roger Trinh[3]; Jay Lalezari[4]; Chia Wang[5]; Laveeza Bhatti[6]; Peter Gulick[7]; Barbara McGovern[3]; Linda Fredrick[3]; Mark Sulkowski[8]

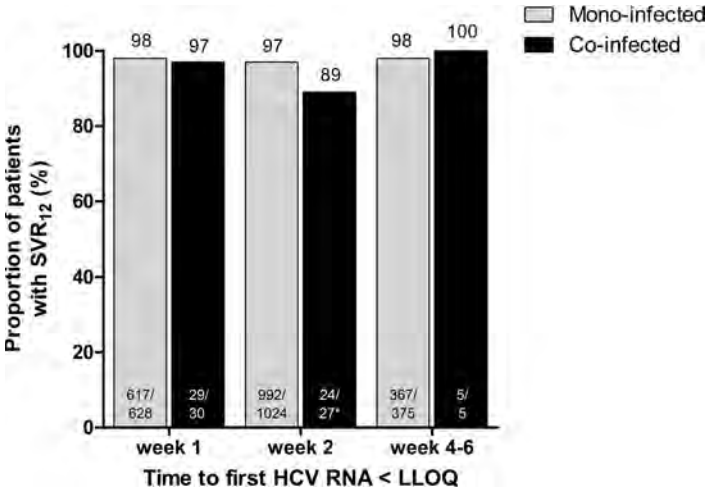
[1]University of California San Diego, La Jolla, CA, US; [2]University of North Carolina, Chapel Hill, NC, US; [3]Abbvie Inc, North Chicago, IL, US; [4]Quest Clinical Research, San Francisco, CA, US; [5]Virginia Mason Medical Center, Seattle, WA, US; [6]AIDS Healthcare Foundation, Los Angeles, CA, US; [7]Michigan State University, East Lansing, MI, US; [8]Johns Hopkins University, Baltimore, MD, US

Background: SVR12 rates >90% have been achieved with the interferon-free 3 direct-acting antiviral regimen (3D) of co-formulated ABT-450 (identified by AbbVie and Enanta)/ritonavir/ombitasvir with dasabuvir +/- RBV in HCV genotype (GT) 1 mono-infected patients. We assessed HCV RNA viral suppression over time in HCV/HIV-1 co-infected patients treated with 3D+RBV and in mono-infected patients treated with 3D+/-RBV.

Methods: Data from the pooled population of HCV GT-1 mono-infected patients from six phase 3 trials of 3D+/-RBV for 12 weeks or 24 weeks (N=2053) and the HCV/HIV-1 co-infected patients from the Phase 2 TURQUOISE-I trial of 3D+RBV for 12 or 24 weeks (N=63) were included. Patients who experienced non-virologic failure were excluded from the

efficacy analysis (N=26 mono-infected; N=1 co-infected). HCV RNA was determined using the Roche COBAS TaqMan RT-PCR assay; lower limit of quantification (LLOQ) =25 IU/ml. SVR_{12} rates were analyzed according to the first week HCV RNA ⟨LLOQ was attained.

Results: Mono- and co-infected patient groups were well matched for IL28B non-CC GT (78% [1607/2053] mono-infected; 81% [51/63] co-infected) and proportion with cirrhosis (19% [384/2053] mono-infected; 19% [12/63] co-infected). More co-infected than mono-infected patients were black (24% [15/63] vs 6% [123/2053], respectively). Most patients achieved HCV RNA ⟨LLOQ by week 2, regardless of mono- or co-infection (1652/2027 [81%] mono-infected, 57/62 [92%] co-infected); stratifying this by cirrhosis state yielded 283/374 (76%) for cirrhotic and 1369/1653 (83%) for non-cirrhotic mono-infected patients and 11/12 (92%) for cirrhotic and 46/50 (92%) for non-cirrhotic co-infected patients. By week 4, the 5 remaining co-infected patients who were not suppressed at week 2 had HCV RNA < LLOQ. Two out of three co-infected patients who achieved HCV RNA ⟨LLOQ at week 2 and did not achieve SVR_{12} had documented HCV re-infection. Similar to mono-infected patients, SVR_{12} rates (despite documented re-infection) in co-infected patients were high (89-100%), regardless of time of initial HCV viral suppression (Figure). The overall safety profile was similar for mono- and co-infected patients.



*Virologic failures occurring in 2 patients appear to have resulted from reinfection based on analyses of baseline and virologic failure samples

Conclusions: Both HCV mono- and HCV/HIV-1 co-infected patients achieved rapid HCV viral suppression with 3D+/-RBV treatment. SVR_{12} rates were high regardless of time of first virologic response.

148 The Paradox of Highly Effective Sofosbuvir Combo Therapy Despite Slow Viral Decline

Thi Huyen Tram Nguyen[1]; **Jérémie Guedj**[1]; Laetitia Canini[2]; Anu Osinusi[5]; Phillip S. Pang[5]; John McHutchison[5]; Henry Masur[6]; Anita Kohli[3]; Shyam Kottilil[4]; Alan S Perelson[2]

[1]IAME, UMR 1137, Inserm, F-75018 Paris, France; Univ Paris Diderot, Sorbonne Paris Cité, F-75018 Paris, France, Paris, France; [2]Theoretical Biology and Biophysics Group, Los Alamos National Laboratory, Los Alamos, NM, US; [3]Clinical Research Directorate/Clinical Monitoring Research Program, Leidos Biomedical Research, Inc, Frederick National Laboratory for Cancer Research, Frederick, MD, US; [4]Laboratory of Immunoregulation, NIAID, NIH, Bethesda, MD, US; [5]Gilead Sciences, Inc, Foster City, MD, US; [6]NIH Clinical Center, Bethesda, MD, US

Background: The SYNERGY trial demonstrated that high cure rates for HCV infection could be achieved after 12 week treatment with sofosbuvir (SOF) and ledipasvir (LDV), and after only 6 weeks if GS-9669 (a non-nucleoside polymerase inhibitor) or GS-9451 (a protease inhibitor) was added *(Kohli et al., The Lancet 2014)*. Here we employed viral kinetic modeling to better understand the effect of each of these drugs in this very rapid and effective cure of HCV.

Methods: In order to evaluate the effect of each agent, we conducted a pooled analysis of the early viral kinetics in patients treated with SOF + ribavirin (RBV) (*Osinusi et al., JAMA 2013*), SOF + LDV and SOF+LDV+GS9669/GS9451. Viral kinetics were fitted using a multiscale model that allows one to distinguish the effect of each agent in blocking vRNA replication, ε_α, from blocking viral assembly/secretion, ε_s *(Guedj et al., PNAS 2013)*.

Results: The viral load decline was initially much more rapid in all arms of Synergy than in patients treated with SOF + RBV. This was attributed in our model to a high effectiveness of LDV in blocking viral assembly/secretion (ε_s=99.7%). In contrast, the delayed response in patients treated with SOF + RBV suggests that SOF has only a minimal effect in blocking assembly/secretion. However by day 3, patients treated with SOF + RBV achieved largely comparable levels of virus as the patients in all arms of Synergy (Fig 1), demonstrating a high effectiveness of SOF in blocking vRNA production (ε_α=99.96%). Surprisingly, the total effectiveness in blocking vRNA production was significantly lower in patients receiving SOF+LDV±GS-9669 (ε_α=96.5%, $P<10^{-10}$) and, to a lesser extent, SOF+RBV±GS-9451 (ε_α=98.5%, $P<10^{-10}$). Eventually, the final phase of viral decline was largely similar in all groups, and similar to that observed with IFN-based therapies.

Consistent with this slow final phase, the model predicted SVR rate of 85.2% after 24 weeks of SOF+RBV, but only 43% and 10% after 12 and 6 weeks of SOF+LDV and SOF+LDV+GS9669/GS9451, respectively, i.e., much lower than what was observed in the Synergy trial.

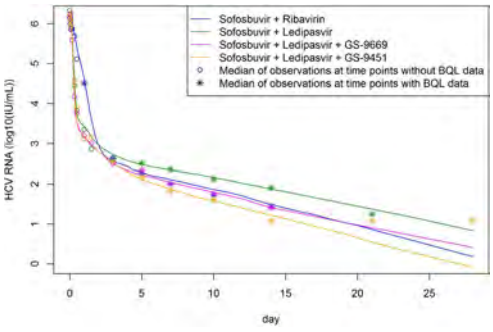


Figure 1: Median observed viral load and median predicted viral decay curves using the multiscale model for different treatment combinations of Synergy and Spare trials. BLQ=below limit of quantification

Conclusions: The kinetics of viral decline in patients of the Synergy trial was remarkably slow in regard of the very rapid cure of HCV. This suggests that HCV RNA is not a reliable marker for predicting outcome of treatment containing SOF+LDV. Additional mechanisms of action that are not reflected in the observed viral load, such as production of non-infectious virus, may explain the high cure rates.

149 Real-World Pharmaceutical Costs in the Simeprevir/Sofosbuvir Era: $164,485 per SVR4

Kian Bichoupan[1]; Neeta Tandon[2]; Rachana Yalamanchili[1]; Neal M. Patel[1]; Sweta Chekuri[1]; Alyson Harty[1]; Thomas Schiano[1]; Ponni V. Perumalswami[1]; Douglas Dieterich[1]; Andrea D. Branch[1]

[1]Mount Sinai School of Medicine, New York, NY, US; [2]Janssen Scientific Affairs, Titusville, NJ, US

Background: Pharmaceutical costs-per-sustained virologic response (SVR4) were determined for patients treated with simeprevir (SMV) and sofosbuvir (SOF) at a large metropolitan medical center.

Methods: The SVR4 rate was calculated for 103 genotype 1 HCV-infected patients who started on SMV- SOF-containing regimens between 12/2013-6/2014. Advanced fibrosis/cirrhosis was defined as a FIB-4 score ≥ 3.25. Costs were based on Red Book Wholesale Acquisition Costs and the number of days on treatment: SMV=$790/d, SOF =$1,000/d, and RBV=$8.58/d. The rate of relapse between 4 and 12 weeks after the end of treatment (EOT) was determined for 41 patients with the necessary follow up data. Episodes of hepatic decompensation and other serious adverse events (SAEs) were noted.

Results: The median age of the 103 patients was 60 years (interquartile range [IQR] = 54-65 years), 14% had HIV/HCV co-infection, 13% were black, 74% were male, 46% had a score ≥ 3.25; 74% had genotype 1a HCV, 25% were naïve to treatment, 28% previously failed therapy with an HCV protease inhibitor. Median baseline laboratory values were as follows: platelet count = 154 x103/μL (IQR: 111-194 x103/μL), albumin = 4.1 g/dL (IQR: 3.8-4.4 g/dL), total bilirubin = 0.7 mg/dL (IQR: 0.5 – 1.0 mg/dL), median log HCV viral load = 6.25 IU/mL (IQR: 5.90 – 6.72 IU/mL). The treatment completion rate for the entire group was 98%, see Table. Overall, 93 (90%) achieved SVR4: SMV/SOF/RBV 77/85 (91%), SMV/SOF 16/18 (89%). Three (2.9%) patients experienced hepatic decompensation/SAE. The SVR4 rates for mono-infected and HIV/HCV patients were 89% and 100% (p=0.35), respectively. The overall mean pharmaceutical cost-per-SVR4 was $164,485. Among 41 patients with the necessary follow up, three (7%) relapsed between week-4 and week-12 post EOT.

Regimen (duration of treatment)	N	FIB-4 ≧ 3.25	Previous protease inhibitor failure	Completed therapy	Serious adverse event or hepatic decompensation	SVR4 rate	Mean cost per SVR4
SOF/SMV/RBV (12 weeks)	85	43 (51%)	27 (32%)	84 (99%)	0 (0%)	77 (91%)	$165,142
SOF/SMV (12 weeks)	18	6 (33%)	2 (11%)	17 (94%)	3 (17%)	16 (89%)	$161,323
Total	103	2 (11%)	29 (28%)	101 (98%)	3 (2.9%)	93 (90%)	$164,485

Cost per SVR by Regimen

Conclusions: In the SMV/SOF era, 98% of patients completed the planned regimen in real world clinical practice. The SVR4 rate was 90% and the mean pharmaceutical cost-per-SVR4 was $164,485. Treatment was highly effective in patients with HIV/HCV co-infection. Rates of decompensation/SAE were < 3%. Surveillance beyond SVR4 is needed to determine the final SVR rate. Seven percent of patients with follow up data relapsed between 4 and 12 weeks EOT.

150 Impact of Deferring HCV Treatment on Liver-Related Events in HIV+ Patients

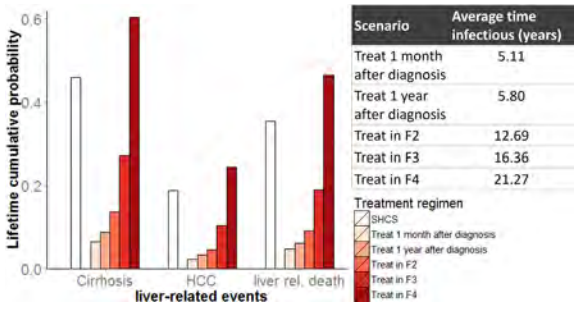
Cindy Zahnd[1]; Luisa P. Salazar-Vizcaya[1]; Jean-François Dufour[2]; Beat Müllhaupt[3]; Gilles Wandeler[1]; Roger Kouyos[3]; Barbara Bertisch[1]; Andri Rauch[2]; Olivia Keiser[1]
The Swiss HIV and Hepatitis C Cohort Studies

[1]Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland; [2]University Hospital Bern, Bern, Switzerland; [3]University Hospital Zurich, Zurich, Switzerland

Background: Successful treatment of HCV infections substantially reduces the risk of liver-related complications. However, cost considerations and the availability of better treatment options in the future often leads to the deferral of treatment of HCV infection in patients with limited liver fibrosis. In this study, we modelled the impact of different treatment strategies on liver fibrosis progression among HIV-infected patients with incident HCV infection.

Methods: We developed an individual-based model of liver disease progression. We parameterized it with observed data on incident HCV infections among men who have sex with men from the Swiss HIV Cohort Study (SHCS) and with published data. We simulated patients from HCV infection through stages of liver disease: from fibrosis grade F0 to F4, decompensated cirrhosis, hepatocellular carcinoma and death. Liver disease progression was affected by age at HCV infection and alcohol consumption. Patients also progressed through the care cascade: they could be diagnosed, treated and succeed or fail treatment. We assumed treatment efficacy with Interferon (IFN)-free regimen was 90%. Successfully treated patients had a residual liver fibrosis progression of 0.1 times the rate of patients with detectable HCV. We compared liver-related events and duration of infectiousness (ie. detectable viral load) between the following strategies: treatment of all patients one month after diagnosis, one year after diagnosis or as they reach F2, F3 or F4.

Results: Delaying treatment until 1 year after diagnosis or until F2, F3 or F4 led to 14, 43, 142 and 418 additional cases of liver-related deaths per 1000 HCV infections as compared with treating all patients one month after diagnosis. The average time people were infectious increased from 5 years with early (one month after diagnosis) to 21 years with late (F4) treatment (*Figure*).



SHCS is our base scenario and is given here for reference, it depicts current practise in the SHCS.

HCC: Hepatocellular Carcinoma

Conclusions: Our model suggests that timely treatment of HCV infection is important: Patients can progress to end-stage liver disease after HCV clearance if treatment is delayed until later stages of liver disease due to imperfect treatment responses and residual fibrosis progression in HIV-infected patients. Delaying treatment also increases the risk of HCV transmission: the average time during which patients are infectious is four times higher if patients are treated in F4 than if they are treated one month after diagnosis.

151LB Daclatasvir in Combination With Sofosbuvir for HIV/HCV Coinfection: ALLY-2 Study

David Wyles[1]; Peter Ruane[2]; Mark Sulkowski[3]; Douglas Dieterich[4]; Anne Luetkemeyer[5]; Timothy Morgan[6]; Kenneth E. Sherman[7]; Zhaohui Liu[8]; Stephanie Noviello[8]; Peter Ackerman[8]

[1]University of California San Diego, La Jolla, CA, US; [2]Ruane Medical and Liver Health Institute, Los Angeles, CA, US; [3]Johns Hopkins University School of Medicine, Baltimore, MD, US; [4]Icahn School of Medicine at Mount Sinai, New York, NY, US; [5]University of California and San Francisco General Hospital, San Francisco, CA, US; [6]VA Long Beach Healthcare System, Long Beach, CA, US; [7]University of Cincinnati College of Medicine, Cincinnati, OH, US; [8]Bristol-Myers Squibb Co, Princeton, NJ, US

Background: The pangenotypic, once-daily combination of daclatasvir (DCV) and sofosbuvir (SOF) achieves high rates of sustained virologic response (SVR) in patients with chronic HCV infection. DCV+SOF has favorable safety and drug-drug interaction profiles and a high barrier to resistance, supporting the phase 3 ALLY-2 study of DCV+SOF in patients with HIV/HCV coinfection.

Methods: This randomized, open-label study enrolled HCV treatment-naive (N=151) or experienced (N=52) adults coinfected with HIV and HCV (any genotype). Naive patients were randomly assigned (2:1), with stratification by cirrhosis status and HCV GT, to receive 12 or 8 weeks of once-daily SOF 400mg + DCV 60mg (dose-adjusted for concomitant antiretrovirals: 30mg with ritonavir-boosted PIs, 90mg with NNRTIs except rilpivirine). Experienced patients received this same regimen for 12 weeks. The primary endpoint was HCV RNA < LLOQ (25 IU/mL) at posttreatment Week 12 (SVR12) in naive GT1 patients treated for 12 weeks.

Results: Treatment arms were well balanced with a median age of 52 y, 87% male, and 62% white/34% black. 83%, 9%, 6%, and 2% of patients, respectively, had GT1, 2, 3, and 4 infection; median baseline HCV RNA was 6.7 log10 IU/mL; 14% had cirrhosis. The median baseline CD4 count was 565 cells/μL and 94% had HIV RNA <50 cp/mL. 99, 50, and 50 patients, respectively, received PI-based, NNRTI-based, or other (primarily INI-based) cART; 4 patients did not receive cART. 199/203 (98%) patients completed therapy; 2 patients discontinued early for noncompliance and 2 for incarceration. Overall, SVR12 was achieved by 97% and 98% of naive and experienced patients, respectively, after 12 weeks of therapy, and by 76% of naive patients after 8 weeks (Table). Among patients treated for 12 weeks, SVR12 rates were similar regardless of prior treatment experience, HCV GT or GT1 subtype, cirrhosis status, concurrent cART regimen, or race. There were no virologic breakthroughs; 2/153 patients (1%) in the 12-week group and 10/50 (20%) in the 8-week group had posttreatment relapse. There were no treatment-related serious AE or AE leading to discontinuation. Treatment-emergent grade 3/4 lab abnormalities included increases in INR (2 patients), AST (1), total bilirubin (8, all received ATV/r), and lipase (7, all transient without pancreatitis).

SVR12, % (n/N)	Naive 12 wk	Exp'd 12 wk	Naive 8 wk
All patients	97 (98/101)	98 (51/52)	76 (38/50)
95% CI	89.8, 99.2	88.0, 99.9	59.7, 87.6
GT 1	**96 (80/83)**[a]	98 (43/44)	76 (31/41)
GT 1a	96 (68/71)	97 (32/33)	80 (28/35)
GT 1b	100 (12/12)	100 (11/11)	50 (3/6)
GT 2	100 (11/11)	100 (2/2)	83 (5/6)
GT 3	100 (6/6)	100 (4/4)	67 (2/3)
GT 4	100 (1/1)	100 (2/2)	-
No cirrhosis	98 (88/90)	100 (34/34)	77 (34/44)
Cirrhosis	89 (8/9)	93 (14/15)	60 (3/5)
White race	96 (63/66)	100 (31/31)	71 (20/28)
Black race	100 (30/30)	95 (19/20)	79 (15/19)

[a]Primary endpoint.

Conclusions: DCV+SOF once daily for 12 weeks achieved SVR12 in 97% of patients coinfected with HIV and HCV GT1, 2, 3, or 4, and was safe and well-tolerated.

152LB Ledipasvir/Sofosbuvir for 12 Weeks in Patients Coinfected With HCV and HIV-1

Susanna Naggie[1]; Curtis Cooper[2]; Michael S. Saag[3]; Jenny C. Yang[4]; Luisa M. Stamm[4]; Phillip S. Pang[4]; John McHutchison[4]; Douglas Dieterich[5]; Mark Sulkowski[6]
On behalf of the ION-4 Study Team

[1]Duke Clinical Research Institute, Durham, NC, US; [2]University of Ottawa, Ottawa, Canada; [3]University of Alabama at Birmingham, Birmingham, AL, US; [4]Gilead Sciences, Inc, Foster City, CA, US; [5]Mount Sinai Health System, New York, NY, US; [6]Johns Hopkins University School of Medicine, Baltimore, MD, US

Background: Historically HIV co-infection was considered a negative predictor of HCV response to treatment with interferon/ribavirin (IFN/RBV). For sofosbuvir-based regimens, HIV/HCV patients have achieved similar sustained virologic response (SVR) rates as HCV monoinfected patients. We evaluated the safety and efficacy of the IFN-free, RBV-free, single tablet regimen of ledipasvir/sofosbuvir (LDV/SOF) in HCV genotype 1 or 4 patients co-infected with HIV-1 in the Phase 3 ION-4 study.

Methods: HCV treatment naïve and experienced HIV co-infected patients on stable, approved antiretroviral (ARV) regimens were enrolled and received LDV/SOF (90mg/400mg) once daily for 12 weeks. Patients with compensated cirrhosis were eligible. Permitted concomitant ARVs included tenofovir and emtricitabine (TDF+FTC) with raltegravir (RAL), efavirenz (EFV) or rilpivirine (RPV). Safety evaluations included adverse event (AE) and standard laboratory parameter monitoring in addition to enhanced renal toxicity monitoring, CD4 count and HIV-1 RNA levels. The primary efficacy endpoint was SVR12.

Results: 335 patients with GT1a (75%), GT1b (23%) and GT4 (2%) were enrolled; 82% were male, 61% were white, mean age was 52 (range 26-72), mean baseline HCV RNA was 6.7 $\log_{10}$ IU/mL (range 4.1-7.8), median baseline CD4 count was 662 cells/uL (Q1, Q3=469, 823), 20% had cirrhosis, 24% were *IL28B* CC genotype and 55% had not responded to prior HCV treatment. Patients were taking EFV (48%) or RAL (44%) or RPV (9%). The table shows SVR12 by ARV regimen. Overall, the SVR12 rate was 96% (320/335); 2 patients had on-treatment virologic failure likely due to non-compliance and 10 had virologic relapse after discontinuing treatment. SVR12 was similar among non-cirrhotic (96%) and cirrhotic (94%) patients and also among treatment naïve (94%) and treatment experienced (97%) patients. No patient had confirmed HIV virologic rebound (HIV-1 RNA≥400 copies/mL). No patients discontinued study drug due to an AE. AEs occurring in ≥10% of patients were headache (25%), fatigue (21%) and diarrhea (11%). No significant lab abnormalities were observed.

Virologic Response	TDF+FTC+EFV (N=160)	TDF+FTC+RAL (N=146)	TDF+FTC+RPV (N=29)	Overall (N=335)
SVR12, n (%)	151 (94)	141 (97)	28 (97)	320 (96)
On-Treatment Failure, n (%)	1 (<1)	0	1 (3)	2 (<1)
Relapse, n (%)	8 (5)	2 (1)	0	10 (3)
Other, n (%)	0	3 (2)	0	3 (<1)

SVR12 by HIV ARV regimen and Overall

Conclusions: The IFN-free, RBV-free, single tablet regimen of LDV/SOF administered once daily for 12 weeks is highly effective and well tolerated in treatment-naïve and experienced, genotype 1 or 4 HCV-infected patients with HIV-1 co-infection, including those with cirrhosis.

Session O-13 Oral Abstracts — Room 6D

10:00 am – 12:15 pm

Reaching Populations: Demonstrating Impact

153 Population Viral Load in Three High HIV Prevalence Settings in Sub-Saharan Africa

David Maman[1]; Helena Huerga[1]; Gilles Van Cutsem[2]; Irene Mukui[3]; Benson Chilima[4]; Beatrice Kirubi[5]; Ruggero G. Giuliani[2]; Elisabeth Szumilin[6]; Charles Masiku[7]; Jean-François Etard[1]

[1]Epicentre/Médecins Sans Frontières, Paris, France; [2]Médecins Sans Frontières, Cape Town, South Africa; [3]National AIDS and STDs Control Program, Nairobi, Kenya; [4]Ministry of Health, Lilongwe, Malawi; [5]Médecins Sans Frontières, Nairobi, Kenya; [6]Médecins Sans Frontières, Paris, France; [7]Médecins Sans Frontières, Lilongwe, Malawi

Background: Viral load (VL) is one of the key factors for HIV transmission. However, at population level, little is known about viral load distribution, especially among those undiagnosed or diagnosed but not on treatment. Critical data to better identify those most at risk of transmitting HIV are needed, particularly in sub-Saharan Africa where most of the transmission occurs.

Methods: Three population-based surveys of persons age 15 to 59 were conducted in Ndhiwa (Nyanza, Kenya), Chiradzulu (Malawi) and Eshowe (Kwazulu-Natal, South Africa) between September 2012 and November 2013 to assess HIV incidence and cascade of care. Each individual who agreed to participate was interviewed and tested for HIV at home. All HIV-positive were tested for VL and CD4, regardless of their ART status. T-test was used to compare means VL (in log10 copies/ml). Multivariate linear regression models were fitted to evaluate factors associated with VL among individuals not on ART.

Results: In total 9,802 houses were visited and among 21,782 individuals eligible, 19,006 (87.5%) were included and tested for HIV. Of the 4,117 individuals who tested positive, 3,938 (95.7%) had their viral load assessed. Population viral suppression (VL<1,000copies/ml) was higher in Malawi (61.9%, 95%CI 58.9-64.5) and South Africa (57.1%, 95%CI 54.5-59.6) than in Kenya (40.0%, 95%CI 37.5-42.6).

Of individuals not receiving ART, overall mean VL was higher among men compare to women (4.61 vs 4.17log cp/mLvs, p<0.01) and among those with CD4 between 500 and 749 cells/μL compared to CD4>750cells/μL (4.23 vs 3.72log cp/mL, p<0.01) but was similar across age groups (4.27, 4.37 and 4.22 log cp/mL for age 15-29, 30-44 and 45-59, respectively, p=0.18). Using the multivariate model, men had a VL higher than women (+0.33 log10 cp/mL, 95%CI 0.22-0.43, p<0.01). VL increased with decreasing CD4. CD4 between 500 and 750 CD4 cells/μL was associated with higher VL compared to CD4>750cells/μL (+0.47 log10 cp/mL, 95%CI 0.33-0.61, p<0.01).

Table: Association between risk factors and mean viral load among participants not receiving ART, multivariate linear regression model (n=1,836)

Factors		Number of patients newly diagnosed n=1,836	Adjusted difference in mean viral load in log cp/mL (95% CI)	*p-value*
Gender				
	Women	1,261	Reference	
	Men	575	0.33 (0.23 – 0.43)	<0.01
CD4 (cells/μL)				
	≥750	292	Reference	
	500-749	499	0.47 (0.33 – 0.61)	<0.01
	350-499	445	0.71 (0.57 – 0.86)	<0.01
	50-349	566	1.11 (0.97-1.25)	<0.01
	<49	34	1.03 (0.69-1.38)	<0.01
HIV Status Awareness				
	Not aware	1,101	Reference	
	Aware	735	-0.01 (-0.10 – 0.07)	0.75

* Also adjusted for age, education and marital status

Conclusions: Among individuals not receiving ART, those with CD4 500-750 cells/μL and men had higher viral load and could be at higher risk of transmitting HIV compared to those with CD4>750 cells/μL and women. Targeting men for HIV testing and treatment and ART initiation at higher CD4 thresholds (750 cells/μL) could contribute to decrease HIV transmission.

154 Disparities in Engagement Within HIV Care in South Africa

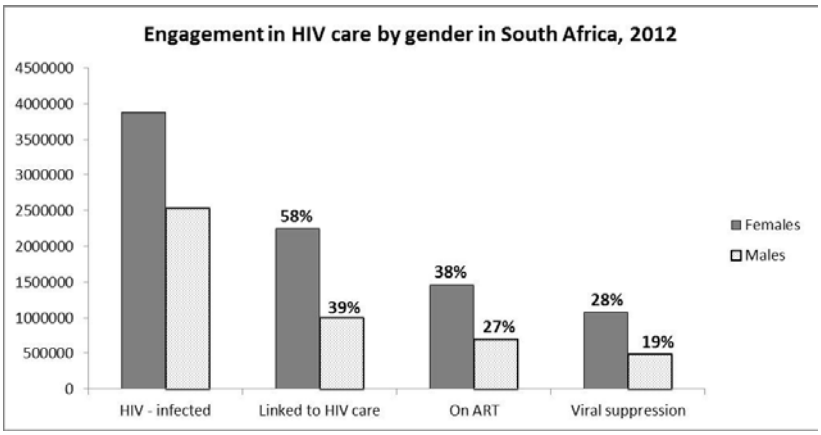
Simbarashe Takuva[1]; Alison Brown[2]; William Macleod[3]; Yogan Pillay[4]; Valerie Delpech[2]; Adrian J. Puren[1]

[1]National Institute for Communicable Diseases, NHLS, Johannesburg, South Africa; [2]Centre for Infectious Diseases Surveillance, Public Health England, London, United Kingdom; [3]Boston University, Boston, MA, US; [4]National Department of Health, Pretoria, South Africa

Background: South Africa (SA) has the largest population of persons living with HIV/AIDS (PLHIVA) in the world. While antiretroviral therapy (ART) provision has rapidly expanded with >2,000,000 people on ART by end of 2012, there were an estimated 400,000 number of new HIV infections in 2012. We characterise engagement within HIV care in 2012 to monitor the effectiveness of the HIV programme and identify areas for improvement.

Methods: National Health Laboratory Service electronic data, a repository for all public sector laboratory measurements in SA were used. Over 3,900,000 CD4 count and viral load measurements conducted in 2012 were extracted, matched then de-duplicated using probabilistic record linkage. The number of PLHIVA was estimated using HIV prevalence estimates from the national household survey. We calculated number and proportion of persons in HIV care, on ART and with viral suppression (viral load<400 copies/ml). We further stratified analysis by gender and age-group. Multivariate regression models were to examine viral suppression rates among those on ART.

Results: Among 6,422,000 PLHIVA in SA in 2012, an estimated 3,300,000 persons (51.4%) accessed care and 34% were on ART. While viral suppression rate was 73.5% among the treated population, the overall percentage of persons with viral suppression among the HIV-infected population was 25.0%, corresponding to potentially 4,500,000 infectious persons. Engagement in care among males was poorer across all stages with only 18.8% with viral suppression (see figure). In the 0-14 age-group, majority in care were on ART (167,000/171,000). Notably, among the sexually active 15-49 year age-group, 47.8% were linked to care, 31.7% were on ART and only 21.5% had viral suppression. Among individuals on ART, males (aPR=0.93, 95%CI 0.93-0.93) and younger persons (aPR=0.94, 95%CI 0.94-0.94; aPR=0.76, 95%CI 0.76-0.76 and aPR=0.77, 95%CI 0.76-0.77 for age-groups 25-49, 15-24 and 0-14 years vs. age 50+ years respectively) were less likely to achieve viral suppression.



Conclusions: Although the number receiving ART has massively increased in SA, an estimated three-quarters of PLWHA have not achieved viral suppression. Expanding HIV testing, strengthening and maintaining prompt linkage to care is crucial. Males and the sexually active 15-49 year age-group have poorer engagement in all stages of care. These groups should be the main focus of prevention efforts as they are potentially driving transmission of new HIV infections in the general population.

155 Decentralizing Access to Antiretroviral Therapy Services for Adults in Swaziland

Andrew F. Auld[1]; Harrison Kamiru[2]; Charles Azih[3]; Andrew L. Baughman[1]; Harriet Nuwagaba-Biribonwoha[2]; Peter Ehrenkranz[1]; Simon Agolory[1]; Tedd V. Ellerbrock[1]; Velephi Okello[3]; George Bicego[1]

[1]US Centers for Disease Control and Prevention, Atlanta, GA, US; [2]ICAP, Columbia University, New York, NY, US; [3]Ministry of Health, Mbabane, Swaziland

Background: In 2007, Swaziland initiated a hub-and-spoke model for decentralizing antiretroviral therapy (ART) access. Decentralization was facilitated through: (1) down-referral of stable ART patients from overburdened central facilities (hubs) to primary healthcare clinics (spokes), and (2) ART initiation at spokes (spoke-initiation). To inform decentralization efforts, a nationally representative retrospective cohort study among adults (≥15 years old) starting ART during 2004–2010, was implemented to assess the effects of down-referral and spoke-initiation on rates of loss to follow-up (LTFU), death, and attrition (death or LTFU).

Methods: Sixteen of 31 ART hubs were randomly selected using probability-proportional-to-size sampling. Seven selected facilities had initiated the hub-and-spoke model by study start. At these facilities, 1,149 of 24,782 hub-initiated and maintained, and 878 of 7,722 down-referred or spoke-initiated patient records were randomly selected. At the nine hub-only facilities, 483 of 6,638 records were randomly selected. Characteristics at ART initiation were compared between hub-only (n=483), hub-initiated and maintained (n=1,149), hub-initiated but down-referred (n=367), and spoke-initiated (n=511) adults. Multivariable proportional hazards regression was used to assess effect of down-referral (a time-varying covariate) and spoke-initiation on outcomes.

Results: At ART initiation, median age was 35, 65% were female, and median CD4 count was 147 cells/μL, with no significant differences in these variables between groups. However, down-referred or spoke-initiated patients tended to have higher median weight, higher functional status, and lower prevalence of tuberculosis treatment at ART start. For down-referred patients, 77% were down-referred after 6 months of ART. Over 5,198 person-years of ART, 107 adults died and 605 were LTFU. Attrition was 20% by 12 months; 3% had died and 16% were LTFU. Controlling for known confounders, down-referral was strongly protective against LTFU [adjusted hazard ratio (AHR) 0.38; 95% CI, 0.29–0.50] and attrition (AHR 0.50; 95% CI, 0.34–0.76) but not mortality. Compared with hub-initiated and maintained patients, spoke-initiated patients had lower LTFU (AHR 0.59; 95% CI, 0.45–0.77) and attrition rates (AHR 0.60; 95% CI, 0.47–0.77), but not mortality.

Conclusions: Down-referral and spoke-initiation within a hub-and-spoke ART decentralization model were protective against LTFU and overall attrition and could facilitate future ART program expansion.

156 Who Are the 10-Year AIDS Survivors on Antiretroviral Therapy in Haiti?

Samuel Pierre[1]; Ashita Batavia[2]; Patrice Severe[1]; Vanessa Rouzier[1]; Benedict Charles[1]; Jean Pape[1]; Warren Johnson[2]; Daniel Fitzgerald[2]; Margaret L. McNairy[2]
On behalf of Les Centres GHESKIO CTU

[1]Les Centres GHESKIO, Port-au-Prince, Haiti; [2]Weill Cornell Medical College, New York, NY, US

Background: Access to antiretroviral therapy (ART) has rapidly expanded over the past decade in resource-limited settings but long-term clinical outcomes of patients, including characteristics of those who have survived for the last decade, have not been reported. We describe the 10-year outcomes and characteristics of the first cohort of patients receiving ART in Haiti.

Methods: Data from 910 ART-naïve patients, age > 13 years, who initiated ART from 2003-4 at GHESKIO were included. Retention was defined as the proportion of patients known to be alive and attending care; lost to follow-up (LTF) was defined as no clinic or pharmacy visit for > 6 months. Cumulative incidence of survival after ART initiation was estimated using Kaplan-Meier methods. Factors associated with LTF and death were assessed using Cox proportional hazard modeling.

Results: Among 910 adults who initiated ART, 55% were female, median age was 38 years (IQR 33-45), and median CD4 was 131 cells/uL (IQR 55-211). Ten years after ART initiation, 477 (52%) patients were retained, 246 (27%) dead, 116 (13%) LTF, and 71 (8%) transferred, with 151 cases of incident TB. The rate of death decreased over time from 25 deaths/100 PY in the first 6 months to 3.60/100 PY (6 months to 5 years) and 1.32/100PY (5 to 10 years). Predictors of death in the first 6 months were age > 50, lowest quartile weight, CD4 < 50 cells/uL, WHO stage III/VI and baseline TB. Death after 6 months was associated with age, both 13-24 and > 50 age groups, and lowest quartile weight. The rate of LTF decreased from 3.91/100 PY in the first 6 months to 1.36/100 PY (6 months to 5 years) and 1.82/100PY (5 to 10 years). Lowest quartile weight was associated with LTF across the 10 years. Among the 473 persons alive and in care at 10 years, median age was 49 (IQR 43-55), 57% were female, median CD4 was 541 cells/uL, and 74% were on first-line therapy. 177 survivors (25%) had documentation of a non-communicable disease (195 cases: 58% hypertension, 3% diabetes, and 39% chronic lung disease).

Conclusions: This analysis documents the long-term effectiveness of an ART program among the first cohort of patients to receive ART in the Caribbean and Latin American Region. Excellent retention and a lower death rate were observed during the 5 to10 year follow-up period as compared to the first 5 years. High prevalence of non-communicable diseases among this population points to the changing needs of aging populations on ART.

157 Nationwide Evaluation of Antiretroviral Therapy Coverage on Prevention in Rwanda: A Multisectional Time-Trend Analysis

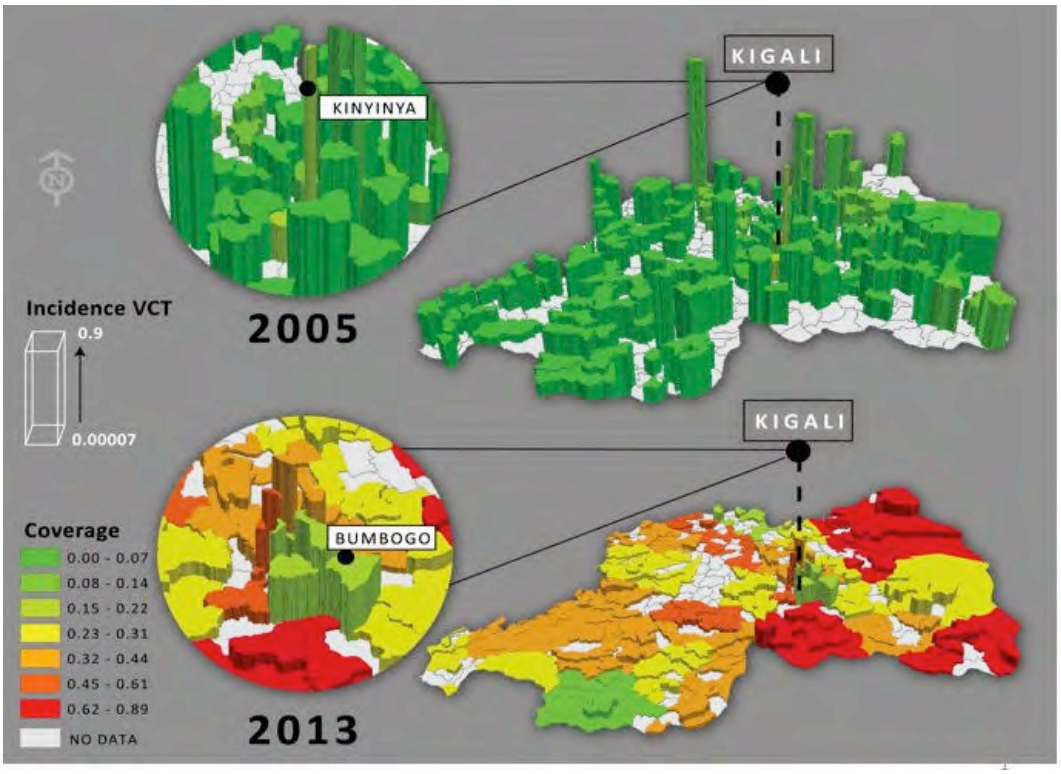
Sabin Nsanzimana[2]; Eric Remera[2]; Steve Kanters[1]; Eric Dusabe[2]; Adeline Dukuze[2]; Till Barnighausen[3]; Eran Bendavid[1]; Julio Montaner[4]; **Edward Mills**[1]
On behalf of the Rwanda Treatment as Prevention Working Group

[1]Stanford University, Vancouver, Canada; [2]Rwanda Biomedical Centre, Kigali, Rwanda; [3]Harvard School of Public Health, Boston, MA, US; [4]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada

Background: Rwanda is one of the most successful countries in terms of antiretroviral therapy (ART) coverage and recently changed guidelines to immediately initiate ART for key groups and at CD4 status of 500 cells/mm^3 among the general population. We aimed to examine the effect of treatment scale-up on the incidence of new infections using a time-staggered causal design.

Methods: We applied a Bayesian hierarchical design that assessed the scale-up of ART across 416 health sectors among 30 districts in Rwanda. We assess the number of infections detected within these health sectors in three-month periods over ten years (2004-2014). We assessed the projected number of new infections per health sector and modeled the change in slope between cases detected and projected cases. We used three different methods to evaluate incidence within each health sector.

Results: In our study period, 123,317 patients initiated ART across Rwanda. Figure 1 displays the reduction in VCT detection and increase in coverage between 2005 and 2013. New cases detected peaked in 2007 and reduced to 12,993 in 2013. We found that for every 10% increase in coverage per health sector, a 6.07 percent reduction in incidence occurred. At the current coverage of 50% of all eligible patients in Rwanda, the effect of ART has contributed a reduction of 26.9% (95% Confidence Intervals [CI] 21.9-31.9%) year by year in a multiplicative way – increasing to 71% by four years. The new target goal of providing ART at 500 cells/mm^3 is estimated to reduce incidence by 36% per year (83% in four years).



Change in positive HIV test detection and ART coverage between 2005 and 2013.

Conclusions: This is, to our knowledge, the first nation-wide evaluation examining the effect of ART on incidence. Our findings demonstrate a large preventive effect associated with ART coverage. As scale-up to new guidelines and targeted populations increase, the preventive effects of ART coverage will likely contribute to greater declines in population incidence.

158 Impact of Male Circumcision Scale-Up on Community-Level HIV Incidence in Rakai, Uganda

Xiangrong Kong[1]; Godfrey Kigozi[2]; Fred Nalugoda[2]; David Serwadda[3]; Maria J. Wawer[1]; Ronald H. Gray[1]
On behalf of the Rakai Health Sciences Program

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [2]Rakai Health Sciences Program, Entebbe, Uganda; [3]Makerere University College of Health Sciences, Kampala, Uganda

Background: Randomized trials show male circumcision (MC) reduces individual level risk of HIV acquisition by 50-60% in men, and MC has been scaled up in sub-Saharan Africa. We assessed the impact of MC coverage on community level HIV incidence among non-Muslim men in Rakai, Uganda.

Methods: The Rakai Community Cohort Study (RCCS) conducts ~ annual surveillance of consenting residents aged 15-49 in 43 rural communities consistently since 1999. Before 2003, MC was largely confined to Muslim men. MC services to non-Muslims were provided through randomized trials during 2004-07 and were scaled up via a PEPFAR program since 2008. For each community, the non-Muslim male population prevalence of MC and HIV incidence per 100 person years (py) was estimated before the MC trials (period 1: 1999 -2003), during the trials (period 2: 2004-07), and since the MC scale up (period 3: 2008-11). Incidence rate ratio (IRR) of community level (CL) HIV incidence associated with CL MC prevalence was estimated by Poisson log-linear regression. Adjusted IRR was also estimated adjusting for potential confounding due to potential population composition change over time (measured by the surrogate of time periods) and CL ART coverage among HIV+s.

Results: In period 1, the mean CL HIV incidence among non-Muslim men was 1.4/100pys (range 0-4.1/100pys); and mean CL MC prevalence was 4.1% (range 1-8%). ART was not available during this period. In period 2, the mean CL HIV incidence was 0.9/100pys (range 0-3.7/100pys), mean CL MC prevalence was 10.0% (range 0-30%), and the mean CL ART prevalence was 5.2% (range 0-13%). In period 3, the mean CL HIV incidence was 1.1/100pys (range 0-3.6/100pys), mean CL MC prevalence was 23.5% (range 0-45%), and mean ART prevalence was 17.9% (range 3-42%). For every 10% increase in CL MC prevalence among non-Muslims, the associated IRR of CL HIV incidence was 0.85 (p=0.006, 95% Confidence Interval [CI] 0.75-0.95). After adjusting for time period and CL ART prevalence, CL MC prevalence had an adjusted IRR of 0.81 (p =0.076, 95% CI 0.65-1.02).

Conclusions: The MC program reached 23.5% coverage among non-Muslim men in Rakai by 2011, with large variations across communities. A 10% increase in community level MC coverage was associated with a 15% (95%CI 5-25%) reduction in CL HIV incidence among non-Muslim men, and this reduction of CL HIV risk was robust after adjusting for potential confounding due to time period and CL ART coverage.

159 Effects of Antiretroviral Treatment on Health Care Utilization in Rural South Africa

Jan A. Hontelez[1]; Frank Tanser[2]; Sake J. de Vlas[1]; Kevindra K. Naidu[2]; Rob Baltussen[3]; Deenan Pillay[2]; Till Barnighausen[2]

[1]Erasmus University Medical Center, Nijmegen, Netherlands; [2]Africa Centre for Health and Population Studies, Somkhele, South Africa; [3]Radboud University Medical Centre, Nijmegen, Netherlands

Background: The impact of the rapid scale-up of vertical antiretroviral treatment (ART) programs for HIV in sub-Saharan Africa on the overall health system is under intense debate. Some argue that HIV treatment programs are draining resources for the treatment of other diseases, while others have claimed that the investments through ART programs benefitted the health system. To establish the population-level impact of ART programs on health care utilization in the public-sector health system, we compare trends in health care utilization among HIV-infected people receiving and not receiving ART with HIV-uninfected people during a period of rapid ART scale-up.

Methods: We used data from one of Africa's largest population-based cohorts, the longitudinal surveillance conducted by the Wellcome Trust Africa Centre for Health and Population Studies, which annually elicits information on health care utilization from all surveillance participants over the period 2009-2012 (N=44,461). We determined trends in hospitalization, and public and private primary health care (PHC) clinic visits for HIV-infected and -uninfected people over the period 2009-2012, and regressed utilization rates by HIV and ART status over time, controlling for sex, age, time on ART, and area of living.

Results: The proportion of people who reported to have visited a PHC clinic in the last 6 months increased significantly over the period 2009-2012, for both HIV-infected people not on ART (from 53% to 60%; p<0.001), and HIV-uninfected people (from 41% to 47%; p<0.001) (figure 1A). In contrast, the proportion of HIV-infected people not on ART visiting a private physician declined from 21% to 13% (p<0.001) (figure 1B) and hospitalization rates declined from 100 to 71 per 1000 PY (p<0.001) (Figure 1C). For HIV-uninfected people, the proportion visiting a private physician declined from 15% to 9%, and hospitalization rates declined from 78 to 44 per 1000 PY (p<0.001). All trends were sustained when controlling for potential confounders.

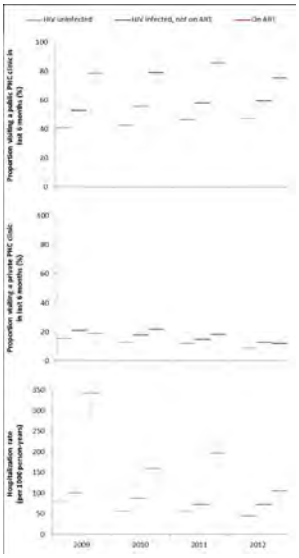


Figure 1. Trend in age-standardized self-reported health care utilization by HIV and ART status over the years 2009 to 2012 in rural KwaZulu-Natal, South Africa. A. Proportion of people reporting to have visited a public PHC clinic in the last 6 months. **B.** Proportion of people reporting to have visited a private PHC clinic in the last 6 months. **C.** Self-reported hospitalization rates over the last 12 months

Conclusions: Our results do not support the claim that ART program scale-up lead to reduced access to care for other diseases. In contrast, the ART program has freed up secondary care capacity and has likely improved both the effectiveness and efficiency of the public-sector health system by channelling utilization from secondary to primary care in this setting. Future health systems interventions should build on these trends to improve the performance of chronic disease management in public-sector primary care.

160 The Impact of PEPFAR Abstinence and Faithfulness Funding Upon HIV Risk Behaviors in Sub-Saharan Africa

Nathan C. Lo; Anita Lowe; Eran Bendavid

Stanford University School of Medicine, Stanford, CA, US

Background: The United States President's Emergency Plan for AIDS Relief (PEPFAR) supports more abstinence and faithfulness programs in sub-Saharan Africa than any other funder. We assess the relationship between PEPFAR's support for these programs and changes in high-risk sexual behavior. Evaluating the outcomes of foreign aid for HIV is important for optimizing HIV treatment and prevention portfolios.

Methods: Using individual-level nationally-representative survey data from the Demographic and Health Surveys for 22 sub-Saharan African countries, we employed a difference-in-differences analysis to assess the relationship of PEPFAR abstinence and faithfulness funding to changes in three outcomes indicative of high-risk sexual behaviors: the number of sexual partners, age of first sexual intercourse, and teenage pregnancies. We compare trends in these outcomes among persons living in PEPFAR funded and non-PEPFAR countries from 1998 to 2013.

Results: We analyzed 252,251 men and 591,714 women using 54 surveys in 14 PEPFAR funded and 8 non-PEPFAR funded countries. In comparison with non-PEPFAR countries, survey respondents living in PEPFAR countries exhibited no relative change in the number of sexual partners among men (0.02 more partners; 95% CI (-0.04, 0.08); p=0.48), number of sexual partners among women (0.02 fewer partners; 95% CI (-0.05, 0.01); p=0.15), age of first sex among men (0.10 years earlier; 95% CI (-0.91, 0.70); p=0.79), age of first sex among women (0.19 years earlier; 95% CI (-0.76, 0.37); p=0.49), or in rates of teenage pregnancy (2% relative decline in prevalence; 95% CI (-7, 2%); p=0.34).

Table: Regression model estimating the changes in high-risk sexual behavior in PEPFAR versus non-PEPFAR countries

	Number of sexual partners, male			
N=251,251	Unadjusted coeff (95% CI)	P-value	Adjusted coeff (95% CI)	P-value
PEPFAR funding	0.10 (-0.07, 0.26)	0.23	0.02 (-0.04, 0.08)	0.48
Education				
Primary education			0.04 (-0.02, 0.10)	0.15
Beyond primary education			0.08 (-0.02,0.18)	0.12
Residence in rural area			0.00 (-0.03, 0.03)	0.93
	Number of sexual partners, female			
N=591,714	Unadjusted coeff (95% CI)	P-value	Adjusted coeff (95% CI)	P-value
PEPFAR funding	-0.04 (-0.08,0.01)	0.11	-0.02 (-0.05, 0.01)	0.15
Education				
Primary education			-0.03 (-0.06, 0.01)	0.13
Beyond primary education			-0.09 (-0.14, -0.04)	<0.01
Residence in rural area			0.01 (-0.01, 0.03)	0.31
Wealth (ownership of car)			-0.03 (-0.04, -0.01)	<0.001
	Age at first sex, male			
N=73,501	Unadjusted coeff (95% CI)	P-value	Adjusted coeff (95% CI)	P-value
PEPFAR funding	0.41 (0.06, 0.76)	0.02	-0.10 (-0.91, 0.70)	0.79
Education				
Primary education			-0.41 (-0.63, -0.19)	<0.01
Beyond primary education			-0.36 (-0.55, -0.18)	<0.01
Residence in rural area			-0.23 (-0.35, -0.11)	<0.01
	Age at first sex, female			
N=179,366	Unadjusted coeff (95% CI)	P-value	Adjusted coeff (95% CI)	P-value
PEPFAR funding	0.23 (-0.05, 0.51)	0.10	-0.19 (-0.76, 0.37)	0.49
Education				
Primary education			0.19 (-0.07, 0.44)	0.14
Beyond primary education			0.90 (0.67, 1.13)	<0.001
Residence in rural area			-0.36 (-0.46, -0.26)	<0.001
Wealth (ownership of car)			0.31 (0.25, 0.37)	<0.001
	Teenage pregnancy			
N=170,399	Marginal effects (95% CI)	P-value	Adjusted marginal effects (95% CI)	P-value
PEPFAR funding	-0.03 (-0.06, 0.01)	0.16	-0.02 (-0.07, 0.02)	0.34
Education				
Primary education			-0.01 (-0.07, 0.06)	0.80
Beyond primary education			-0.21 (-0.28, -0.15)	<0.001
Residence in rural area			0.07 (0.05, 0.09)	<0.001
Wealth (ownership of car)			-0.11 (-0.13, -0.09)	<0.001

Note: Country-level covariates of GDP per capita (USD), population (millions), and contraception prevalence were included in analysis, but not shown in table due to near-zero coefficients and statistical insignificance.

Conclusions: We find no evidence to suggest that PEPFAR funding of abstinence and faithfulness programs results in reduced high-risk sexual behavior. These results suggest the importance of examining alternative funding priorities for PEPFAR to improve HIV prevention in sub-Saharan Africa.

161 The Impact of Antiretroviral Therapy on Adult Life Expectancy in Sub-Saharan Africa

Georges Reniers[8]; Jeffrey Eaton[1]; Jessica Nakiyingi-Miiro[2]; Amelia C. Crampin[4]; Chodziwadziwa Kabudula[5]; Kobus Herbst[3]; Mark Urassa[6]; Amek Nyaguara[7]; Emma Slaymaker[8]
ALPHA Network

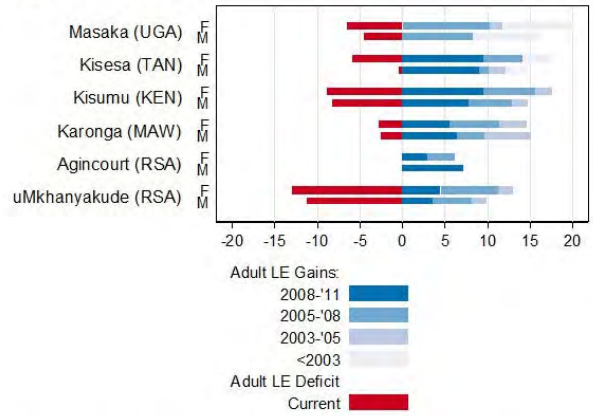
[1]Imperial College London, London, United Kingdom; [2]MRC/UVRI Uganda Research Unit on AIDS, Entebbe, Uganda; [3]Africa Centre for Health and Population Studies, Mtubatuba, South Africa; [4]Karonga Prevention Study, Chilumba, Malawi; [5]University of the Witwatersrand, Johannesburg, South Africa; [6]National Institute for Medical Research, Mwanza, United Republic of Tanzania; [7]Kenya Medical Research Institute-Centers for Disease Control, Kisumu, Kenya; [8]London School of Hygiene and Tropical Medicine, London, United Kingdom

Background: Few studies directly measure the population-wide impact of antiretroviral therapy (ART) on adult mortality, with most existing estimates relying on extrapolations from ART coverage. We use demographic surveillance data from seven study sites in six eastern and southern African countries to estimate (i) gross adult life expectancy (LE) gains since the introduction of ART, (ii) net LE gains attributable to ART, and (iii) the remaining LE deficit due to HIV.

Methods: We use non-parametric survival analysis for estimating the LE of adults aged 15 years and above. The gross LE gain is defined as the difference in the overall LE between two calendar years; the current LE deficit due to HIV is the difference in the LE of HIV negatives and the LE for the population as a whole. Net LE gains attributable to ART are obtained by fitting a model of age-specific HIV incidence and survival to estimate the counterfactual LE in the absence of ART. Estimates are presented for the years 2000 to 2012, and disaggregated by sex and study site.

Results: The pooled dataset contains 655,227 adults, contributing over 3 million person-years of follow up time and 46,898 deaths. Gross adult LE gains range from 8 to 20 years (Figure 1); net LE increases attributable to ART are between 4 and 19 years. Gross LE gains are largest in eastern Africa, where mortality reductions also benefited from historical declines in HIV incidence, but the effect of ART (net LE gains) is largest in South Africa, where LE would have continued to decline without ART. The current LE deficit is around 10 years in sites with the highest HIV prevalence (Kisumu and uMkhanyakude); in other sites the LE deficit is now under 5 years (Figure 1). On average, women have gained 3.4 more adult life-years than men, but their current LE deficit is still between 0.6 and 5.4 years larger.

Figure 1: The gross adult LE gains to date (blue) and the current LE deficits (red), by sex (F/M) in six ALPHA Network study sites



Notes: The LE deficit cannot be computed Agincourt because HIV status information is only available for a small sample. Estimates for Manicaland (ZIM) are in preparation.

Conclusions: Gross adult LE gains between 10 and 15 years are norm and driven by the expansion of treatment, and in the eastern African study sites also by prior declines in HIV incidence. Large LE deficits due to HIV remain, however, and are indicative of the need for enhancing program coverage and impact. Women have generally gained more life-years than men, and that is due to gender differences in the uptake of services and treatment outcomes, women's younger ages at infection, and women's lower background mortality. Despite larger LE gains to date, women still lose more life-years to HIV than men.

Session O-14 Oral Abstracts — Room 613

Immune Mechanisms: The Road to Protection

162 Passively Acquired ADCC Activity in HIV-Infected Infants Correlates With Survival

Caitlin Milligan[1]; Barbra A. Richardson[1]; Grace John-Stewart[2]; Ruth W. Nduati[3]; Julie M. Overbaugh[1]

[1]Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US; [2]University of Washington, Seattle, WA, US; [3]University of Nairobi, Nairobi, Kenya

Background: Antibody-dependent cellular cytotoxicity (ADCC) activity has been described as a potential immune correlate of protection from HIV infection in macaques and humans. The role of ADCC activity mediated by passively acquired antibodies (Abs) in HIV-exposed infants is unknown and was examined to determine if pre-existing HIV-specific antibodies provide protection from infection and/or disease progression.

Methods: We evaluated the ADCC activity of passively acquired Abs in the first week of life from infants of HIV-positive mothers. Infants were included based on the following criteria: HIV-RNA negative at birth, breastfed ≥3 months, ≥6 months follow-up of negative infants. Seventy-two infants were included, 21 of who were first detected as HIV positive after birth. Infant plasmas were tested against an infant-derived, subtype A envelope using a rapid fluorometric ADCC assay. HIV-specific IgG1 was measured by binding to gp120 coated target cells and quantified by flow cytometry. IgG3 HIV-specific Ab titers were measured by ELISA. Comparisons of measurements in infected and uninfected infants were made by 2-sided Welch's t-test. Survival analyses were conducted using Cox-proportional hazards models. Spearman's rank correlation was used for correlation analyses.

Results: Passively acquired ADCC activity was higher in uninfected infants than infected infants, but was not statistically significant (p=0.12). In infected infants, pre-existing ADCC activity was associated with increased survival: each 10% increase in ADCC activity was associated with a 49.1% reduction in the risk of mortality (p=0.03). ADCC activity positively correlated with the magnitude of HIV-specific IgG1 surface binding, measured as $\log_2$MFI(r=0.92, p<0.0001). The magnitude of surface IgG1 binding was also associated with survival in infected infants (HR:0.24, p=0.005). IgG3 binding Ab end point titers were not associated with infant infection (p=0.25) or survival (p=0.63). In measurements of longitudinal ADCC activity from 6 infected infants, passively acquired ADCC activity declined to undetectable levels prior to an increase in *de novo* responses. *De novo* ADCC responses did not correlate with passively acquired responses (r=-0.14, p=0.79).

Conclusions: These data suggest that HIV-specific, ADCC-mediating passively acquired Abs may impact disease progression and survival among infected infants. In particular, IgG1 and not IgG3 Abs appear to be responsible for the effect and *de novo* responses do not explain the survival benefit.

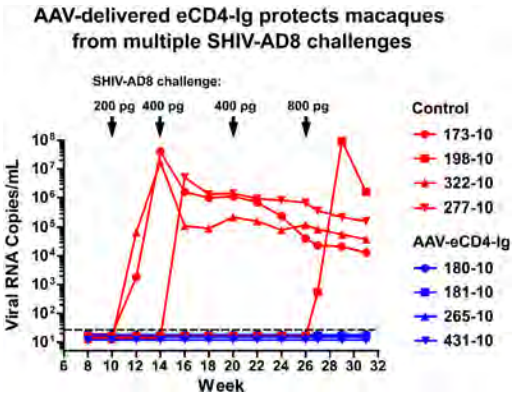
163 AAV-Expressed eCD4-Ig Protects Rhesus Macaques From Multiple SHIV-AD8 Challenges

Michael Farzan
The Scripps Research Institute, Jupiter, FL, US

Background: Long-term *in vivo* expression of a broad and potent entry inhibitor could circumvent the need for a conventional HIV-1 vaccine. Adeno-associated virus (AAV) vectors can stably express broadly neutralizing HIV-1 antibodies (bNAbs). However, more than a quarter of HIV-1 isolates are at least partially resistant ($IC_{80} > 5$ μg/ml) to even the best bNAbs, suggesting that very high concentrations of these antibodies would be necessary to achieve general protection.

Methods: Here we characterize eCD4-Ig, a fusion of CD4-Ig with a small CCR5-mimetic sulfopeptide, and assess AAV-delivery of eCD4-Ig as a means of stably protecting individuals from a new HIV-1 infection.

Results: We show that eCD4-Ig binds avidly and cooperatively to the HIV-1 envelope glycoprotein (Env) and is more potent than the best bNAbs (geometric mean $IC_{50} < 0.05$ μg/ml). Because eCD4-Ig only binds conserved regions of the Env, it is also much broader than any bNAb. For example, eCD4-Ig neutralized 100% of a diverse panel of neutralization-resistant HIV-1, HIV-2, and SIV isolates with IC_{80}s less than 5 μg/ml, including a comprehensive set of isolates resistant to the CD4-binding site bNAbs VRC01, NIH45-46, and 3BNC117. Rhesus macaques inoculated with an AAV vector expressed 16-84 μg/ml of fully functional rhesus eCD4-Ig over 32 weeks, and these macaques were protected from multiple challenges with SHIV-AD8 that efficiently infected control macaques. Moreover, eCD4-Ig was markedly less immunogenic than any of four well characterized bNAbs.



Conclusions: AAV-expressed eCD4-Ig can function as an effective HIV-1 vaccine alternative.

164LB HIV Neutralizing Antibodies Induced by Native-Like Envelope Trimers

Rogier Sanders
The WCMC/Scripps/AMC HIVRAD team
Academic Medical Center University of Amsterdam, Amsterdam, Netherlands

Background: Inducing HIV-1 neutralizing antibodies against neutralization-resistant (Tier-2) virus strains has been a challenge.

Methods: Our working hypothesis has been that stable native-like envelope trimers should induce neutralizing antibodies (NAbs).

Results: We show here that such trimers based on the pediatric founder virus BG505 (BG505 SOSIP.664 gp140), consistently induced neutralizing antibodies (NAbs) against the autologous, neutralization-resistant (Tier-2) BG505.T332N virus at high titers in rabbits and macaques. Cross-reactive NAbs against more sensitive (Tier-1) viruses were also induced. The Tier-1 and the autologous Tier-2 NAb responses were uncorrelated, implying that different pathways and B-cell subsets are involved. Tier-1 NAbs were depleted by linear V3 peptides, while Tier-2 NAbs recognized several conformational epitopes that differed between animals, that sometimes involved glycosylation sites and that were similar to some broadly active NAb epitopes. We have designed amino acid substitutions that further stabilize and antigenically improve BG505 SOSIP.664 trimers. The same substitutions also allowed the generation of stable native-like trimers based on virus isolates from clades B and C, including a clade B isolate from an elite neutralizer that developed broad neutralization within 9 months post seroconversion. Finally, we designed a stable native-like trimer that is able to interact with the germline versions of diverse bNAbs.

Conclusions: These rationally designed trimers represent suitable starting points for lineage and/or polyvalent vaccines aimed at inducing NAbs able to counter diverse Tier-2 isolates.

165 Efficacy Loss of BnAbs During HIV-1 Cell-Cell Spread Is Strain- and Epitope-Dependent

Lucia Reh; Carsten Magnus; Merle Schanz; Jacqueline Weber; Therese Uhr; Peter Rusert; Alexandra Trkola
University of Zurich, Zurich, Switzerland

Background: HIV-1 cell-cell transmission promotes high efficacy of infection, which inflicts a dramatic loss in neutralization potency even by broadly neutralizing antibodies (bnAbs) compared to free virus infection. A precise definition of inhibitory potentials during cell-cell transmission is therefore needed to select bnAbs that are capable of suppressing HIV irrespective of the transmission mode, securing in vivo activity and allowing for their use as vaccines and in passive immunization.

Methods: We have compiled assay systems that allow for unambiguous discrimination between free virus and cell-cell transmission. For this, PBMC or CD4+ CCR5+ A3.01 T cells were co-cultured with producer cells (PBMC or 293-T cells), either infected with replication competent virus or transfected with env pseudotyped inGLuc reporter viruses to distinguish cell-cell transmission from fusion events. Inhibitory capacities of the bnAbs (b12, VRC01, NIH45-46, 3BNC117, PGV04, PGTs 121, 125, 128, 135, 145, PG9, PG16, 2G12, 10E8, 2F5, 4E10) during cell-cell transmission of HIV-1 strains from subtypes A, B and C were studied and their potency to block virus transmission pre and post CD4 engagement was assessed.

Results: Across almost all bnAb-virus combinations tested, the potency to inhibit HIV-1 cell-cell transmission was strongly decreased compared to free virus transmission. However, loss of potency varied considerably between virus strains and strikingly, high potency against free virus did not ensure lower loss in activity during cell-cell transmission.

In rare bnAb-virus combinations, inhibition capacities proved comparable for both transmission modes but no bnAb that potently blocked cell-cell transmission over a range of HIV-1 strains could be identified. Likewise, the capacity of bnAbs to block HIV infection post CD4 engagement differed among virus strains and bnAbs tested.

Importantly, mathematical analysis employed to estimate the consequences of the observed activity loss during cell-cell transmission indicated an increased probability of viral resistance mutations to arise in cell-cell rather than free virus spread.

Conclusions: Our data suggest that the efficacy of bnAbs during cell-cell transmission cannot be predicted by their free virus activity and greatly differs in a strain-dependent manner. Potent inhibition of both transmission routes will only be possible through a combination of bnAbs, either by multi-component vaccines or antibody cocktails in passive immunization.

166 Peripheral T Follicular Helper Cells With Universal Helper Activity in HIV Infection

Bruce Schultz; Alexander Oster; Franco Pissani; Jeffrey E. Teigler; Michael A. Eller; Merlin L. Robb; Jerome H. Kim; Nelson L. Michael; Diane Bolton; **Hendrik Streeck**

US Military HIV Research Program, Silver Spring, MD, US

Background: Immunogen design to generate protective neutralizing antibodies is a central effort in HIV vaccine development and critically dependent on T follicular helper (T_{FH}) cells. However, very little is known about the peripheral counterpart of HIV-specific T_{FH} cells and the protein-specific help they might provide.

Methods: Biomark Fluidigm gene expression profiles from HIV-specific IL-21+ and IFNγ+ CD4 T cells were analyzed from chronic, treatment-naïve HIV-infected individuals. Epitope specificity of peripheral T_{FH} cells and Th1 cells was defined by Elispot. HIV-specific T_{FH} cell lines were generated and their functionality and phenotype assessed by flow cytometry. Helper activity of Gag-and Env-specific T_{FH} cells were tested in a CD4-B cell as well as CD4-CD8 T cell co-culture assay. HIV-specific T_{FH} responses from ALVAC/AIDSVAX and DNA/Ad5 vaccine recipients were also compared.

Results: HIV-specific IL21+CD4 T cells showed significantly higher expression of genes associated with T_{FH} cells compared to IFNγ+ or IL21+/IFNγ+ CD4 T cells including BCL6, cMaf and CXCR5. IL21+CD4 T cells most closely resembled T_{FH} cells compared to any other phenotypic description of pT_{FH} cells. Besides CXCR5+, HIV-specific pT_{FH} cells predominantly expressed ICOS and PD1 but were CCR7-. The frequency of HIV-specific pT_{FH} cells was low when compared to HIV-specific IFNγ+CD4 cells ($p<0.0001$). Interestingly, while HIV-specific IFNγ+CD4 T cells dominantly targeted epitopes in Gag, HIV-specific T_{FH} cells equally recognized epitopes within Gag and Env ($p=0.0009$). Gag- and Env-specific T_{FH} cells were able to provide help to HIV-specific CD8 T cells *in vitro*, characterized by Perforin/GrzB induction. In contrast, however, Gag-specific T_{FH} cells preferentially induced maturation and proliferation of B cells, while Env-specific T_{FH} cells predominantly drove Ig class switching. Further analysis revealed that Env-specific T_{FH} cells also displayed features indicative of Th2 cells compared to Gag-specific T_{FH} responses ($p=0.0003$). Lastly, we found that ALVAC/AIDSVAX vaccine recipients had significantly higher levels of HIV-specific pT_{FH} cells but comparable levels of HIV-specific Th1 cells as DNA/Ad5 vaccine recipients.

Conclusions: Given the evidence presented here for the role that IL21+CD4 T cells appear to play in the maturation of vaccine evoked humoral immune responses, these findings have clear implications for HIV vaccine design.

167 Redirected Killing of HIV-Infected T Cells by Germinal Center CD8 T Cells

Constantinos Petrovas[1]; Sara Ferrando-Martinez[1]; Michael Gerner[2]; Amarendra Pegu[1]; Perla Del Río-Estrada[3]; Kristin Boswell[1]; Manuel Leal[4]; Gustavo Reyes-Teran[3]; Ronald Germain[2]; Richard A. Koup[1]

[1]Vaccine Research Center, National Institute of Allergy and Infectious Diseases, Bethesda, MD, US; [2]NIAID-NIH, Bethesda, MD, US; [3]Instituto Nacional de Enfermedades Respiratorias, Mexico City, Mexico; [4]Instituto de Biomedicina de Sevilla, Sevilla, Spain

Background: Follicular helper CD4 T cells (T_{FH}) are located within the germinal centers (GC) of lymph nodes (LN) and represent a major contributor to the latent reservoir. Bispecific antibodies that target HIV Env and CD3 are being developed to eliminate the latent reservoir by activating HIV from CD4 T cells and inducing killing of those cells by CD8 T cells. We characterized the localization, frequency, and function of CD8 T cells in GCs to determine if they were present and capable of killing HIV-expressing cells in the context of HIV Env/CD3-targeting bispecific antibodies.

Methods: The phenotype, localization and function of CD8 T cells in tonsils and LNs from non-infected and HIV-infected viremic individuals was investigated. Polychromatic flow cytometry was used for phenotypic analysis and confocal imaging for spacial localization. Histo-Cytometry was performed for the quantitative analysis of GC cell populations. Function (IFN, TNF, MIP-1, and Perforin, GzB production) was assessed by intracellular staining after stimulation with anti-CD3. (5 hour). In vitro cytolytic activity of sorted CD8 T cell populations was tested in a killing assay using an anti-HIV Env/anti-CD3 bispecific-antibody. Cytokines and soluble cell death mediators were analyzed by Luminex.

Results: Phenotypic analysis of tonsillar cells revealed a memory population of CD8 T cells expressing a $CCR7^{low}CXCR5^{high}$ profile compatible with follicular localization. Histo-Cytometry analysis confirmed the presence of a small population of CD8 T cells within the GC. These GC CD8 T cells were expanded in HIV-infected LNs compared to non-infected tonsils. Follicular CD8 T cells (defined by CXCR5 expression and loss of CCR7) exerted a superior killing capacity judged by in vitro mobilization of GzB/Perforin. Production of MIP-1 and GzB predominated over IFN and TNF production in GC CD8 T cells. Of all tissue CD8 T cell populations tested, GC localized CD8 T cells had the greatest ability to mediate killing of HIV-infected target cells after cross-linking with an anti-HIV Env/anti-CD3 bispecific antibody.

Conclusions: HIV infection is characterized by accumulation of CD8 T cells within LN follicles. These CD8 T cells are functionally capable of mediating bispecific antibody-mediated killing of HIV-infected CD4 T cells. These data add credence to the use of bispecific antibody therapy to purge the LN reservoir

168 IL-21 Reduces Inflammation and Virus Persistence in ART-Treated SIV-Infected Macaques

Luca Micci[1]; Emily Ryan[1]; Colleen McGary[1]; Sara Paganini[1]; Guido Silvestri[1]; Mike Piatak[2]; Jeffrey Lifson[2]; Francois Villinger[1]; Jason M. Brenchley[3]; Mirko Paiardini[1]

[1]Yerkes National Primate Research Center, Emory University, Atlanta, GA, US; [2]Leidos Biomedical Research, Inc, Frederick, MD, US; [3]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD, US

Background: Residual inflammation persists and critically contributes to non-AIDS-related morbidity/mortality in ART-treated, HIV-infected subjects. Furthermore, inflammation may contribute to HIV persistence during ART. Interleukin (IL)-21 regulates the differentiation and maintenance of IL-17- and IL-22- producing CD4 T cells, which depletion critically contributes to chronic immune activation and disease progression in HIV and SIV infection. In this study, we investigated the effects of Interleukin (IL)-21 administration in chronic, ART-treated SIV-infected rhesus macaques (RMs) on mucosal integrity, residual inflammation, and virus persistence.

Methods: Sixteen RMs were infected with SIV_{mac239} i.v. and, starting at day 60 post-infection, treated for seven months with PMPA, FTC, Raltegravir, Darunavir and Ritonavir. Eight RMs received IL-21-Fc (100 mg/kg, s.c., weekly for six weeks) at the beginning and the end of ART, with the other eight serving as ART- treated controls. Blood, lymph nodes and rectum were longitudinally collected, and the effects of IL-21 on inflammation, T cell subset levels, and viral persistence assessed. The Mann-Whitney test was used for statistical analyses.

Results: ART was very effective, with fully suppressed plasma viremia (<60 SIV-RNA copies/ml) in all RMs. Compared to ART-controls, ART+IL-21 RMs showed improved restoration of intestinal Th17 and Th22 cells ($P<0.01$ for both subsets). Remarkably, IL-21-treated RMs showed a faster and more pronounced reduction in the levels of activated ($HLA\text{-}DR^{+}CD38^{+}$) and proliferating ($Ki\text{-}67^{+}$) T cells in rectum and blood during ART ($P<0.01$), and maintained level of T cell activation significantly lower than controls up to eight months following ART-interruption ($P<0.01$). Between days 75 to 200 on-ART, IL-21-treatment elicited a higher number of RMs with undetectable (<3 copies/mL) SIV-vRNA in

plasma (P<0.03). Furthermore, rectal cell associated SIV-DNA levels were significantly reduced between d75 and d200 on-ART in IL-21-treated RMs (P<0.01) but not in controls. Finally, only IL-21-treated animals maintained plasma viral loads significantly lower than those at pre-ART up to eight months post-ART interruption.

Conclusions: These data provide evidence of a link between mucosal immunity, inflammation, and HIV persistence. Furthermore, they suggest that IL-21 may provide important therapeutic benefits when used as an adjunctive immunomodulatory agent in ART-suppressed HIV-infected individuals.

169 Discovery of CD8+ T Cell Epitopes Encoded by the HIV 5′ Leader Sequence

Edward Kreider[1]; Katja J. Pfafferott[2]; Thomas Partridge[2]; Hui Li[1]; Ranjit Warrier[1]; Benedikt M. Kessler[2]; Andrew J. McMichael[2]; Persephone Borrow[2]; Beatrice H. Hahn[1]; George M. Shaw[1]
[1]University of Pennsylvania, Philadelphia, PA, US; [2]University of Oxford, Headington, United Kingdom

Background: The HIV-1 5′ leader consists of the RNA upstream of canonical coding regions, encodes essential replicative functions, and exhibits the highest degree of conservation within the viral genome. We hypothesized that the 5′ leader, despite its designation as the 5′ "untranslated region," encodes previously uncharacterized open reading frames (ORFs) that are expressed from AUG-like start codons and harbor epitopes that are recognized by host T cell responses.

Methods: Single genome sequencing (SGS) was conducted on plasma virus from HIV-1-infected humans. Interferon-γ ELISPOT and intracellular cytokine staining were performed on PBMCs stimulated with autologous peptides or putative escape variants encoded by the 5′ leader sequence. Mass spectrometry analysis of major histocompatibility complex (MHC)-presented epitopes was conducted on peptides purified using MHC immunoprecipitation, acid elution, and reverse phase liquid chromatography of lysates from HIV-IIIB infected CD4+ T cells. Ribosomal profiling was used to identify AUG-like translation initiation sites.

Results: SGS of virus from HIV-1-infected humans demonstrated mutational patterns suggestive of virus escape throughout the 5′ leader. Based on these escape patterns, 4 potential ORFs were identified: one in the transactivation response element (TAR), one within U5, one surrounding the dimerization initiation signal (DIS), and one around the major splice donor. Screening for a T cell response to autologous transmitted/founder and putative escape peptides from these ORFs revealed CD8+ T cell recognition of an epitope within the DIS stem loop ORF. Mass spectrometry analysis of MHC-bound peptides from HIV-IIIB-infected T cells revealed presentation of two overlapping TAR peptides, LA14 and LL8. Ribosomal profiling demonstrated translation initiation at one-off AUGs within these two newly identified ORFs. Analysis of sequences in the Los Alamos HIV compendium showed that 91% of Group M viruses encode a DIS stem loop ORF and 93% of non-Clade A Group M viruses encode a TAR ORF.

Conclusions: We report here the discovery of multiple previously unrecognized ORFs in the HIV-1 5′ leader, or 5′ "untranslated region." Peptides from these ORFs are presented on infected CD4+ T cells and can target these cells for T cell recognition. The discovery of a novel source of T cell epitopes within such a highly conserved and functionally important region of the genome has implications for both vaccine development and immunopathogenesis research.

170LB Neutralizing Antibodies Differ Between HIV-1–Infected RV144 Vaccinees and Placebos

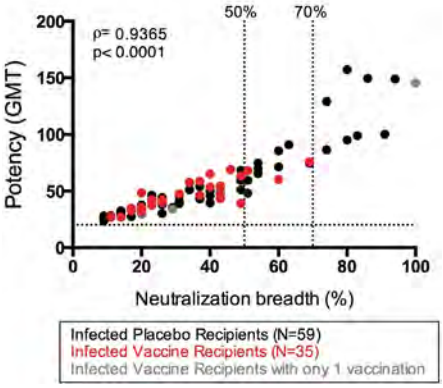
Shelly J. Krebs[1]; Morgane Rolland[1]; Sodsai Tovanabutra[1]; Ivelin Georgiev[2]; Agnes-Laurence Chenine[1]; Victoria R. Polonis[1]; Supachai Rerks-Ngarm[3]; Peter D. Kwong[2]; Nelson L. Michael[1]; Jerome H. Kim[1]
on behalf of the RV152 Study Group
[1]US Military HIV Research Program, Silver Spring, MD, US; [2]Vaccine Research Center, NIAID, NIH, Bethesda, MD, US; [3]Ministry of Public Health, Bangkok, Thailand

Background: Elucidating the ontogeny of broadly neutralizing antibodies (NAb) within infected individuals may identify important factors to consider in vaccine development. Although NAbs were not a correlate of risk in the RV144 HIV vaccine trial, B cell priming by vaccination may have accelerated the production of specific NAb lineages after infection. We asked if RV144 vaccine recipients who became infected elicited NAbs that varied in breadth, potency, and specificity compared to RV144 infected placebo recipients.

Methods: Samples from 94 infected RV144 individuals were evaluated for NAbs at 1-3 years post-diagnosis prior to the initiation of ART. Using a high-throughput robotic microneutralization assay, samples were analyzed against a panel of 35 viruses from subtypes A, B, C, D, CRF_01 AE, and CRF_02 AG. Included within this panel were 21 pseudoviruses where the pattern of neutralization can predict NAb specificity. Neutralization breadth, potency, and specificity of the responses observed after infection were compared between the vaccine and placebo recipients.

Results: Aggregate analysis revealed breadth and potency of neutralization were highly correlated (ρ= 0.94; p<0.001; Fig.1). Seventeen (29%) placebos while only 3 (10%) vaccine recipients neutralized >50% of the 35 virus panel (Fig.1). At three years post-diagnosis (956-1198 days), 8 placebo and 1 vaccine recipients neutralized >70% of the panel (Fisher's exact test, p=0.08), noting that the single vaccine recipient had only received 1 out of the 6 RV144 immunizations (Fig. 1). A trend toward increased breadth in the placebo group compared to the vaccine group (median= 40 vs 30, p=0.08) was also observed. The CD4 binding site and/or MPER were predicted as the dominant NAb specificities from both the placebo and vaccine groups, at 77% and 63% respectively.

Fig. 1: RV144 Neutralization



Conclusions: We report differences in neutralization breadth and potency between infected vaccine and placebo recipients of RV144. These data suggest a restriction in the vaccine group in the ability to produce broad NAb responses post-infection compared to the placebo group, raising the hypothesis that infected vaccinees define a group with intrinsically less effective HIV-1 immune responses. Further studies will provide a better understanding of the development of antibody responses in HIV-1 infected subjects, the potential role of vaccination on post-infection humoral responses, and the interrelationship between HIV-1 evolution and antibody responses.

Themed Discussion Abstracts

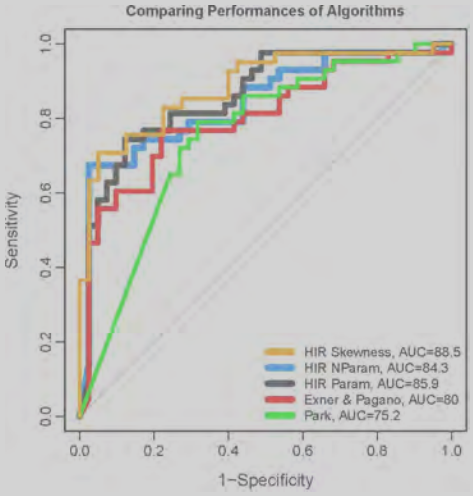
612 A Generalized Entropy Measure of Viral Diversity for Identifying Recent HIV-1 Infections

Julia W. Wu; Oscar Patterson-Lomba; Marcello Pagano
Harvard School of Public Health, Boston, MA, US

Background: There is a need for incidence assays that accurately estimate HIV incidence based on cross-sectional specimens. Viral diversity-based assays have shown promises but are not particularly accurate. We hypothesize that certain viral genetic segments are more predictive of recent infection than others and aim to improve assay accuracy by employing classification algorithms that focus on the highly informative regions (HIR).

Methods: We analyzed HIV *gag* sequences from a cohort in Botswana. Forty-two subjects newly infected by HIV-1 Subtype C were followed longitudinally through 500 days post-seroconversion. Using sliding window analysis, we screened for genetic segments within *gag* that best differentiate acute versus chronic infection. We used both non-parametric and parametric approaches to evaluate the discriminatory abilities of sequence segments. Segmented Shannon Entropy measures on HIRs were aggregated to develop generalized entropy measures to improve prediction of recency, defined as infection within past 6 months. With logistic regression as the basis for our classification algorithm, we evaluated the predictive power of these novel biomarkers and compared them with recently reported viral diversity measures using Area under the Curve (AUC) analysis. To further improve prediction, we also explored other diversity-related biomarkers.

Results: Change of diversity over time varied across different sequence segments within *gag*. The top 50% most informative segments were identified through non-parametric and parametric approaches. In both cases HIRs were in non-flanking regions and less likely in the *p24* coding region. These new indices outperformed previously reported viral-diversity-based biomarkers. Including skewness in the assay further improved the AUC (see Figure 1), whereas other existing methods did not add much additional predictive power. Sensitivity analysis suggests that antiretroviral use had little impact on our assay performances. We also demonstrate that sensitivity and specificity depend on the datasets used and the underlying distributions of time-since-infection. This explains why we obtained different AUC values compared to previous studies.



Comparing predictive performances of different algorithms.

Conclusions: Our generalized entropy measure of viral diversity demonstrates the potential for improving accuracy when identifying recent HIV-1 infections. We also show that to properly compare and evaluate assay performances, the distribution of time-since-infection in the validation dataset needs to be accounted for.

626 Viral Load is Critical in Limiting False-Recent Results From HIV Incidence Assays

Reshma Kassanjee[1]; Shelley Facente[2]; Sheila Keating[3]; Elaine McKinney[4]; Kara Marson[2]; Christopher D. Pilcher[2]; Michael Busch[3]; Gary Murphy[4]; **Alex Welte**[1]
The Consortium for the Evaluation and Performance of HIV Incidence Assays (CEPHIA)
[1]*South African DST/NRF Centre of Excellence in Epidemiological Modelling and Analysis (SACEMA), University of Stellenbosch, Stellenbosch, South Africa;* [2]*University of California San Francisco, San Francisco, CA, US;* [3]*Blood Systems Research Institute, San Francisco, CA, US;* [4]*Public Health England, London, United Kingdom*

Background: The cross-sectional use of (biomarker) tests for recent HIV infection in principle offers affordable, low-bias options for incidence estimation. For currently available assays, viral suppression (due to elite control or antiretroviral treatment) is predictive of long-term infections being ('falsely') classified as 'recent'. Surveillance requires a not-too-transient 'mean duration of recent infection' (MDRI) – preferably at least 6 months. Assay readings below a chosen threshold are interpreted as indicating 'recent' infection, and any assay threshold sufficiently high to achieve a large MDRI inevitably incurs a substantial 'false-recent rate' (FRR), which should preferably be no higher than 1%. The performances of seven assays (BED, Limiting Antigen (LAg), Less-Sensitive (LS) Vitros, Vitros Avidity, BioRad Avidity, Architect Avidity, Geenius) were compared, in stand-alone form and in conjunction with a rule that low viral load is indicative of non-recent infection, allowing for varying assay and viral load thresholds.

Methods: Specimens were used from a growing repository, previously described, of over 6000 specimens representing over 2000 subjects from studies in Africa, Brazil and the United States. Assay thresholds were adapted to produce the same MDRI, estimated by binomial regression. Within a model scenario inspired by the contemporary South African context, the net model population-level FRRs were estimated by combining FRR estimates for key subgroups (stratifying by time since infection and treatment status).

Results: Table 1 shows the model population-level FRR for each assay, using an assay threshold that provides an MDRI of 200 days in each case, used either alone or with a viral load rule (using viral load thresholds of 75 and 1000 copies/ml).

Long-infected population	False-recent rate[1]								
	Treatment-naïve[2]			Treated and virally-suppressed			Treatment coverage of 30%		
Viral load threshold (copies/ml)	0	75	1000	0	75	1000	0	75	1000
Architect Avidity	3.9%	4.3%	4.7%	43.1%	0.0%	0.0%	15.7%	3.0%	3.3%
BED	2.1%	2.2%	2.7%	60.4%	0.0%	0.0%	19.6%	1.5%	1.9%
BioRad Avidity	0.8%	0.9%	1.0%	20.9%	0.0%	0.0%	6.8%	0.6%	0.7%
Geenius	3.9%	4.1%	4.4%	68.7%	0.0%	0.0%	23.4%	2.9%	3.1%
LAg	0.6%	0.5%	1.1%	60.5%	0.0%	0.0%	18.5%	0.4%	0.8%
LS-Vitros	4.3%	3.9%	3.3%	67.2%	0.0%	0.0%	23.1%	2.7%	2.3%
Vitros Avidity	3.3%	3.4%	3.3%	61.6%	0.0%	0.0%	20.8%	2.4%	2.3%

[1] For a choice of assay threshold that produces an MDRI estimate of 200 days; MDRI estimated using binomial regression (logit link with a cubic polynomial of time since infection as the predictor)

[2] Survival of treatment-naïve population follows a Weibull distribution with a mean of 10 years and standard deviation of 2.5 years; probability of 'recent' result analysed using binomial regression (described above)

Table 1: False-recent rates for recent infection testing algorithms

Conclusions: Adapted to provide a standard desirable MDRI of 200 days, none of the assays, used alone, provide an acceptably low FRR. With the use of any realistic viral load threshold, the FRR values drop dramatically, to between 0.4% and 3.3%, which is operationally feasible for population-level surveillance in high incidence contexts. Increasing the viral load threshold above 75 copies/ml offered little improvement in FRRs while decreasing MDRIs. Methods for optimally combining all information about predictors of 'false-recent' results into real-world context-specific FRR estimates require further development. Also, judicious combinations of these assays could potentially yield further improvements in performance.

625 False Recent Rates for Two Recent Infection Testing Algorithms, South Nyanza, Kenya

Clement Zeh[1]; David Maman[4]; Harrison Omondi[2]; Alex Morwabe[2]; Collins Odhiambo[2]; Beatrice Kirubi[4]; Irene Mukui[3]; Martinus W. Borgdorff[1]; Jean-François Etard[4]; Andrea A. Kim[1]

[1]US Centers for Disease Control and Prevention, Kisumu, Kenya; [2]Kenya Medical Research Institute, Kisumu, Kenya; [3]National AIDS and STI Control and Prevention, Nairobi, Kenya; [4]Médecins Sans Frontières, Paris, France

Background: Evaluation of candidate tests for recent HIV infection (TRI), designed to distinguish recent from chronic HIV infection, is an essential step prior to estimating cross-sectional HIV incidence. The TRI's false-recent rate (FRR), the probability that a chronic infection will misclassify as recent, is a required parameter for calculating HIV incidence and should not exceed 2% for accuracy. Because the FRR varies by TRI and sub-population, the FRR should be assessed in all settings in which HIV incidence will be estimated. We compare the FRR for the Limiting Antigen Avidity Enzyme Immunoassay (LAg) and Bio-Rad Avidity Enzyme Immunoassay (Bio-Rad), respectively, in a high HIV prevalence setting in South Nyanza, Kenya.

Methods: We conducted a population-based household survey of persons aged 15-59 years in Ndhiwa District in South Nyanza, Kenya. HIV treatment naive participants with documented chronic HIV infection (defined as testing HIV+ in the survey and reporting the first HIV+ test result ≥12 months preceding the survey) were tested for recent infection using the LAg and Bio-Rad on serologic blood samples. Recent infection was defined based on two recent infection testing algorithms (RITA): 1) a multi-assay algorithm (MAA) which defined a recent case as: a) tested recent on the TRI; b) not virally suppressed defined as HIV-1 RNA concentration ≥400 copies/mL; and 2) a single-assay algorithm (SAA) which defined a recent case as tested recent on the TRI. The FRR was calculated by dividing the number of recent cases observed on the RITA by the number of chronic infections tested.

Results: Of 1,465 HIV-positive samples, 835 (57.0%) were chronic infections. Based on the MAA, the FRR was 0.5% (95% CI 0.01 – 1.0) for LAg and 2.4% (95% CI 1.4 – 3.4) for Bio-Rad. Based on the SAA, the FRR was 4.6% (95% CI 3.2 – 6.0) for LAg and 7.2% (95% CI 5.5 – 9.0) for Biorad. The FRR did not differ by sex and RITA, but varied by age group for the two RITAs. In the MAA, the FRR was highest among youth aged 15-24 years (1.2%; 95% CI 0 – 3.5 for LAg; 3.5%; 95% CI 0 – 7.4 for Bio-Rad). In the SAA, the FRR was highest among persons aged 45-59 years at 5.7%; 95% CI 2.8 – 8.6 for LAg and 8.9%; 95% CI 5.4 – 12.5 for Bio-Rad.

Conclusions: The recommended threshold for a FRR was met by LAg, but only in the MAA which excluded individuals with suppressed viral load. Performance of the TRIs using the SAA resulted in high FRRs that are inappropriate for estimating incidence.

622 The Effect of HIV-1 Subtype A, C and D on Cross-Sectional Incidence Assay Performance

Andrew F. Longosz[2]; Mary Grabowski[2]; Charles S. Morrison[3]; Ronald H. Gray[2]; Connie Celum[4]; Quarraisha Abdool Karim[5]; Hilmarie Brand[6]; Thomas C. Quinn[1]; Susan H. Eshleman[2]; **Oliver B. Laeyendecker**[1]

[1]National Institute of Allergy and Infectious Diseases, Baltimore, MD, US; [2]Johns Hopkins University, Baltimore, MD, US; [3]FHI 360, Durham, NC, US; [4]University of Washington, Seattle, WA, US; [5]CAPRISA, University of KwaZulu-Natal, Congella, South Africa; [6]SACEMA, Stellenbosch University, Stellenbosch, South Africa

Background: We examined the impact of HIV subtype A, C and D on the performance of serologic cross-sectional HIV incidence assays.

Methods: Three assays were evaluated: the limiting antigen avidity enzyme immunoassay (LAg-Avidity assay), the BED capture enzyme immunoassay (BED-CEIA), and an avidity assay based on the Genetic Systems 1/2 + O ELISA (BioRad-Avidity assay). We evaluated 4,821 plasma and serum samples from individuals known to be infected with HIV-1 subtypes A, C and D from 6 different cohort studies in Zimbabwe, Uganda, South Africa, Kenya, Zambia and Botswana. This study included 2,045 subtype A samples (212 samples from the 2008-2009 Rakai Community Cohort Study (RCCS) and 1,833 samples from the Ugandan Genital Shedding (GS) Study. 1,697 subtype C samples (329 samples from the Ugandan and Zimbabwean GS Studies, 85 samples from HPTN 039, 727 samples from the Partners in Prevention Study and 556 samples from the CAPRISA 004 Trial Group) were analyzed. 1,079 subtype D samples (781 samples from the Ugandan Genital Shedding (GS) Study and 298 samples from the 2008-2009 RCCS) were tested. Date of HIV seroconversion was defined as either the midpoint between the last negative and first positive HIV antibody test, or fifteen days after acute infection was documented (defined as HIV RNA positive / HIV antibody negative). Viral load and HIV-1 subtype data were determined previously in parent studies. Mean duration of recent infection (MDRI) was calculated for subtypes A, C and D using a time window of two years post-seroconversion. To define recent infection, assay cutoffs of 1.5 normalized optical density (OD-n), 0.8 OD-n and 40% avidity index (AI), were used for the LAg-Avidity assay, BED-CEIA, and Bio-Rad-Avidity assay respectively. The false recent rate (FRR), the fraction of samples misclassified as recent, was calculated for all samples and those with detectable viral loads (>400 cps/ml).

Results: There were significant differences for MDRI and FRR estimates by subtype for all three assays (see Table). The largest differences in MDRI were seen for the LAg-Avidity and BED-CEIA assays between subtypes A and D. FRR results were significantly higher for subtype D for all three assays.

Table. Estimated test properties (95% confidence intervals) for each assay, by subtype

Recent/nonrecent threshold (unit)	Number of subjects (data points)	LAg-avidity 1.5 OD-n	BED 0.8 OD-n	BioRad avidity 40% AI
MDRI (days)[a]				
Subtype A	82 (577)	160.5 (144.6-175.7)	291.5 (278.0-303.6)	121.7 (111.7-132.8)
Subtype C	490 (1115)	127.9 (117.0-137.9)	204.9 (194.5-215.3)	138.0 (128.7-147.5)
Subtype D	30 (223)	204.6 (178.2-228.9)	281.0 (258.2-301.1)	150.6 (120.8-180.5)
FRR (%)				
Subtype A	290 (1468)	1.36 (0.83-2.09)	15.0 (13.2-17.0)	0.27 (0.07-0.70)
Subtype C	491 (582)	2.58 (1.44-4.22)	7.39 (5.40-9.82)	0.86 (0.28-1.99)
Subtype D	329 (856)	12.4 (10.3-14.8)	19.9 (17.2-22.7)	13.7 (11.4-16.2)
FRR (%) for VL+				
Subtype A	290 (1352)	0.52 (0.21-1.06)	13.3 (11.5-15.2)	0.30 (0.08-0.76)
Subtype C	451 (547)	2.38 (1.27-4.03)	6.95 (4.96-9.41)	0.73 (0.20-1.86)
Subtype D	328 (705)	6.24 (4.57-8.29)	13.6 (11.2-16.4)	13.8 (11.3-16.5)

AI, avidity; FRR false recent rate; LAg, limiting antigen avidity; MDRI mean duration of recent infection; OD-n, normalized optical density; VL+, viral load > 400 cps/ml;
[a]using a T = 2 years

Conclusions: The performance of each of the three assays varied by HIV subtype and subtype D had the highest false recent rates. These results highlight the need to optimize and validate testing algorithms for cross-sectional HIV incidence estimation in populations with the relevant HIV subtype distributions

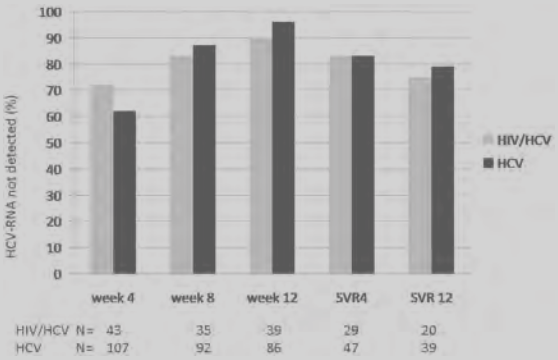
646 German Cohort on Sofosbuvir-Based Therapy for HIV/HCV and HCV Infection (GECOSO)

Stefan Christensen[2]; Ingiliz Patrick[3]; Dietrich Hueppe[7]; Thomas Lutz[4]; Karl Georg Simon[6]; Knud Schewe[5]; Heiner Busch[2]; Axel Baumgarten[3]; Guenther Schmutz[1]; **Stefan Mauss**[1]
[1]Center for HIV and Hepatogastroenterology, Duesseldorf, Germany; [2]CIM Infectious Diseases, Muenster, Germany; [3]Medizinisches Infektiologie Zentrum Berlin, Berlin, Germany; [4]Infektiologikum, Frankfurt, Germany; [5]Infektionsmedizinisches Centrum Hamburg, Hamburg, Germany; [6]Practice for Gastroenterology Leverkusen, Leverkusen, Germany; [7]Practice for Gastroenterology Herne, Herne, Germany

Background: Sofosbuvir (SOF) was approved in Europe in January 2014 with limited study data. In particular, interferon based triple therapy in HIV/HCV coinfection and pretreated patients were not systematically studied. Here, we present real-life data on SOF-based treatments from Germany.

Methods: In this multicenter cohort, all patients who were started on the following treatment regimens were documented: SOF/ribavirin (RBV), SOF/daclatasvir, SOF/simeprevir, and SOF/PegIFN/RBV. For the current analysis due to the limited observational period only patients treated with PegIFN/RBV/SOF were analysed. In February 2015 complete data sets for the first three therapy regimen will be available.

Results: Overall, 266 patients were enrolled so far. Of those, 193 were HCV-monoinfected and 73 HIV/HCV-coinfected. The genotype (GT) pattern was: GT1 n=156, GT2 n=17, GT3 n=68, GT4 n=24. Liver cirrhosis was present in 85/266 (32%) patients. Pretreated patients were 134/266 (50%). 161 (61%) patients were treated with SOF/PegIFN/RBV. The SVR12 rate overall was 78%.The viral response under therapy did not substantially differ between HIV/HCV coinfection and HCV-monoinfection (see figure). In addition SVR 4 and 12 were comparable. One patient showed a non-response (HCV) and one got re-infected under therapy with a different genotype (HIV/HCV). So far <5% of patients discontinued therapy prematurely or were lost to follow up.



Conclusions: In this preliminary analysis, response rates for HIV/HCV-coinfected and HCV-monoinfected patients treated with SOF/PegIFN/RBV were similar. The SVR12 rate seems to be lower than in the NEUTRINO study despite a low discontinuation rate. The lower SVR rate may be attributable to the cohort population containing more difficult-to-treat patients.

649 Successful HCV Treatment With Direct Acting Antivirals in HIV/HCV Patients

Jennifer L. Grant[1]; Valentina Stosor[1]; Frank J. Palella[1]; Richard M. Green[1]; Guajira Thomas[1]; Donna V. McGregor[1]; Milena M. McLaughlin[2]; Sudhir Penugonda[1]; Michael Angarone[1]; **Claudia Hawkins**[1]
[1]Northwestern University, Feinberg School of Medicine, Chicago, IL, US; [2]Midwestern University, Chicago, IL, US

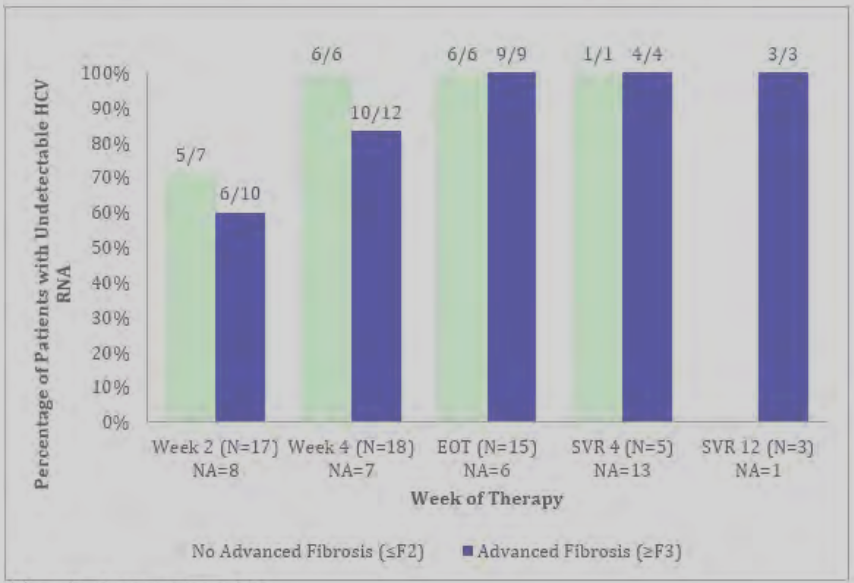
Background: IFN-free combinations of direct acting antivirals (DAA) are associated with high cure rates in HCV-infected patients. The SOF/SMV combination has not yet been studied in HIV/HCV co-infected persons. We evaluated outcomes in HIV/HCV patients receiving IFN-free DAA therapy in a large urban clinic in Chicago.

Methods: In a prospective observational analysis of HCV treatment experienced and treatment naïve co-infected adults (≥18 years) enrolled in the Northwestern University Viral Hepatitis Registry from Jan-Sep 2014, we evaluated the efficacy and safety of SOF/RBV (24 weeks) and SOF/SMV (12 weeks). HCV virologic responses were assessed at week 2 and then monthly during therapy (Rx) and 4 and 12 weeks after completion of Rx (SVR 4 and 12). HCV relapse was defined as a detectable HCV-RNA (lower limit of detection 15 IU/mL) at 4 or 12 weeks after Rx completion. We used chi-square and students' T-test (SPSS version 22.0, Armonk, NY; IBM Corp.) for between group comparisons.

Results: We evaluated 42 HIV/HCV patients [median age 53 years (IQR 47, 60); 81% male; 50% Caucasian; median CD4+ T cell count 522 cells/mm^3 (IQR 292, 660)] for HCV Rx. Risk factors for HCV included MSM (41%) and IDU (41%). Rx was initiated in 32/42 (76%) patients with either SOF/SMV (28, 87.5%) or SOF/RBV (4, 12.5%). Males (85.3% vs. 25% (females); p<0.01) and patients with higher mean FibroSure™ scores (0.70 vs. 0.46; p=0.047) were more likely to receive HCV Rx. There were 21 (66%) with genotype (GT) 1a, 8 (25%) with GT 1b, and 1 each (3%) with GT 2, 3 and undifferentiated. 14/32 (44%) had previously received either PEG/RBV (12/14) or PEG/RBV+BOC (2/14). Median pre-Rx HCV-RNA was 1,384,532 copies/ml (IQR 798,853, 3,772,827) and 23/32 (72%) had advanced liver fibrosis (≥F3). All patients received indicated ART. HCV-RNA responses are shown in Figure

1. No HCV relapses have occurred to date in patients receiving either DAA Rx. Minor adverse effects occurred in 14/29 (48%) patients, none of which resulted in HCV therapy discontinuation (pruritus, 17%, fatigue, 14%, grade 3 total bilirubin elevation, 10%). One death occurred unrelated to HCV Rx.

Figure 1.
HCV Virologic Outcomes in HIV/HCV Patients Receiving SOF/SMV



*All p-values for comparisons >0.05
**NA=lab data not available

Conclusions: In this non-clinical trial-based study of difficult to treat HIV/HCV-infected patients, use of SOF/SMV or SOF/RBV achieved rapid HCV-RNA declines and was well tolerated. HIV co-infection should not be considered a barrier to successful HCV treatment using these combinations. Accrual and treatment of patients is ongoing.

645 Effectiveness of Sofosbuvir/Simeprevir for HIV/HCV Patients in Clinical Practice

Jody Gilmore[1]; Kenneth Lynn[1]; Delisha Breen[1]; Stacey Trooskin[2]; Jihad Slim[3]; Nancy Scangarello[3]; Alvin Kingcade[4]; Katie Hunyh[4]; Vincent Lo Re[1]; **Jay R. Kostman**[1]

[1]Perelman School of Medicine, Philadelphia, PA, US; [2]Drexel University College of Medicine, Philadelphia, PA, US; [3]St Michael's Medical Center, Newark, NJ, US; [4]Philadelphia Health Management Corporation, Philadelphia, PA, US

Background: HIV/HCV-coinfected patients have been underrepresented in clinical trials of all-oral therapies for chronic HCV genotype 1 infection. Our objective was to assess virologic responses and tolerability of sofosbuvir + simeprevir (sof/sim) in HIV/HCV-coinfected patients compared to those with HCV alone.

Methods: We performed a cohort study among HCV-infected patients treated with sof/sim at 4 community-based and academic centers. The main outcome was end-of-treatment (EOT) HCV virologic response. HCV RNA, liver aminotransferases, and sof/sim discontinuations were evaluated over 12 weeks of treatment and 12 weeks of follow-up. Results were stratified by HIV status and by the presence of advanced hepatic fibrosis/cirrhosis.

Results: Eighty-one patients (37 coinfected; 44 monoinfected) were treated with sof/sim between 12/2013 and 9/2014. Fifty-nine percent were African American, 61% were male, 73% had METAVIR stage 3/4 fibrosis, and 46% had prior HCV therapy (49% null or partial responders; 16% relapsers; 35% stopped due to toxicity). The most common HIV regimens in coinfected persons included raltegravir, dolutegravir, or rilpivirine with either tenofovir/emtrictabine or abacavir/lamivudine. Among HIV/HCV patients, 54% and 87% achieved an HCV RNA that was not quantifiable at 2 and 4 weeks of therapy, respectively, compared to 55% and 81% for HCV-monoinfected patients ($p>0.5$). Those with METAVIR stage 3/4 were equally likely to achieve HCV suppression by 4 weeks compared to those with less fibrosis regardless of HIV status (61% vs. 67% in coinfected patients, $p=0.68$; 56% vs. 75% in monoinfected patients, $p=0.33$). Overall, mean levels of alanine aminotransferase decreased from 54 U/L to 22 U/L within 2 weeks of sof/sim initiation. Of the 81 patients, only 5 (6%; 3 coinfected; 2 monoinfected) prematurely discontinued therapy (1 due to nonresponse; 1 for cutaneous reaction; 3 lost to follow-up). Among 42 patients completing 12 weeks of therapy, 37 (88%) achieved an EOT response (89% in coinfected patients; 88% in monoinfected patients, $p>0.5$). At the time of this analysis, 22 patients were followed for at least 4 weeks after the completion of therapy with 2 virologic relapses in monoinfected patients, 1 with METAVIR stage 3/4.

Conclusions: An all-oral sof/sim regimen was effective for patients with chronic HCV genotype 1, regardless of HIV status, previous treatment response, and stage of fibrosis. Adverse events were rare, even in patients with advanced fibrosis/cirrhosis.

648 Simeprevir and Sofosbuvir Regimens for Hepatitis C: Decompensation and Serious AEs

Ponni V. Perumalswami[1]; Kian Bichoupan[1]; Lawrence Ku[1]; Neal M. Patel[1]; Rachana Yalamanchili[1]; Thomas Schiano[1]; Mark Woodward[2]; Douglas Dieterich[1]; Andrea D. Branch[1]

[1]Icahn School of Medicine at Mount Sinai, New York, NY, US; [2]George Institute for Health at the University of Oxford, Oxford, United Kingdom

Background: New therapies for hepatitis C virus (HCV) were well-tolerated in registration trials; however, results in real world clinical practice can be different. We characterized hepatic decompensation and serious adverse events (SAEs) in patients receiving standard care at the Mount Sinai Medical Center.

Methods: All HCV infected patients treated with regimens that contained sofosbuvir (SOF) and/or simeprevir (SMV) were included. The Cases experienced at least one of the following: hepatic decompensation, indicated by new or increased jaundice, ascites, encephalopathy, or sepsis, or another SAE. There were two cohorts: Cohort 1 included 466 patients, Cohort 2 included 43 liver transplant (LT) patients. The incidence of decompensation/SAE was calculated for each cohort. Within each cohort, a matched Case-Control study was performed to identify risk factors for decompensation/SAE. For Cohort 1, up to five Controls were selected for each Case based on treatment regimen and duration. For Cohort 2, matching was 1:2. Cases and Controls were compared using matched conditional exact analysis.

Results: A total of 489 patients met the inclusion criteria: 466 in Cohort 1 (non-LT) and 43 in Cohort 2 (LT). There were 13 non-LT Cases (2.8%) and 8 LT Cases (19%), $p< 0.01$ for the comparison. In Cohort 1, most (62%) were on SOF/RBV, 15% were on SOF/PEG/RBV, and 23% were on SMV/SOF. Among 67 non-LT patients on PEG/RBV-free regimens, three

decompensated/experienced an SAE (4%). In Cohort 2, all were on SOF/RBV. Treatment was discontinued in 4/13 (31%) of non-LT Cases and in 2/8 (25%) of LT Cases. Similar to registration trials, liver decompensation/SAE lead to treatment discontinuation in 1% (5/466) of the entire non-LT Cohort and in 5% (2/43) of the entire LT Cohort. Among non-LT patients, risk factors for SAE/decompensation included low baseline albumin, high INR, and high total bilirubin. In LT patients, lower hemoglobin, eGFR, ALT, AFP and higher serum creatinine were risk factors for SAE/decompensation.

Conclusions: This study identified subgroups of non-LT and LT patients who may require more intensive monitoring and additional interventions to successfully complete SMV- and SOF-based treatment regimens. Patients with reduced hepatic biosynthetic function and LT patients were especially vulnerable to serious AEs and decompensation (DA031095, DK090317).

651 Majority of HIV/HCV Patients Need to Switch ART to Accommodate Simeprevir

Rebecca Cope[1]; Aaron Pickering[2]; Thomas Glowa[1]; Samantha Faulds[1]; Peter Veldkamp[1]; **Ramakrishna Prasad**[1]

[1]University of Pittsburgh, Pittsburgh, PA, US; [2]University of Maryland, Glen Burnie, MD, US

Background: The impact of drug-drug interactions (DDIs) between Simeprevir (SMV) and antiretrovirals (ART) in limiting HCV treatment among HIV/HCV co-infected individuals in clinical practice settings is unknown. We determined: a) the need to switch antiretroviral therapy (ART) prior to initiation of SMV; and b) the feasibility of switching ART to allow SMV use. We hypothesized that the majority of co-infected patients will require an ART switch and a safe and effective ART switch will be challenging in patients on a protease inhibitor (PI) based ART regimen.

Methods: A retrospective chart review was conducted at the University of Pittsburgh Medical Center's HIV/AIDS Program from June-August 2014. All patients with HIV and chronic HCV with a visit in the past 18 months were included. After collection of baseline characteristics, significant interactions between SMV and ART were identified based on available literature. If DDIs limited use of SMV, previous HIV genotype reports were reviewed to determine the feasibility of a safe and effective ART switch.

Results: Of 133 patients, 71% were male, 54% African American, 23% met criteria for advanced liver disease, 86% had HCV genotype 1, and 94% were currently on ART. The distribution of regimens was: ritonavir-boosted PI (PI/r) (38%); efavirenz (34%); raltegravir (11%); rilpivirine (6%); elvitegravir/cobicistat (1%); and other regimens including dolutegravir (4%). An ART switch to allow use of SMV was required in 103 (77%), most frequently for patients on efavirenz or a PI/r. For 47 (46%), a straightforward substitution could be made. For the remaining patients, a switch following HIV expert opinion was viable in 40 (39%), but no switch was possible in 16 (15%) due to archived HIV drug resistance mutations. Notably, for more than 30% of patients on a PI, an ART switch was not feasible.

Conclusions: The majority of HIV/HCV co-infected patients will require ART switch prior to use of SMV. Additionally, for nearly a third of patients on a PI, an ART switch may not be feasible. These findings are significant to real world clinical practice settings and highlight the complexity of using Interferon-free DAAs in this population and add further stress to an already burdened HIV care delivery system.

644 Sofosubuvir, Simeprevir, +/- Ribavirin in HCV Protease Inhibitor-Experienced Patients

Kristen M. Marks; Ethan M. Weinberg; Sonal Kumar; Carrie Down; Ype P. de Jong; Leah A. Burke; Mary C. Olson; Ira M. Jacobson

Weill Cornell Medical College, New York, NY, US

Background: Little data exists on use of HCV protease inhibitors (PIs) as part of a treatment (Rx) regimen for PI-experienced G1 patients (pts). Since polymorphisms associated with PI-resistance decrease to baseline levels over time in most studied subjects, sofosbuvir (SOF) + simeprevir (SMV) +/- ribavirin (RBV) represents a *potential* retreatment option for PI-experienced pts.

Methods: We compiled a retrospective cohort of HCV PI-experienced G1 pts treated with SOF+SMV+/-RBV at our center. Baseline factors including prior regimen & Rx response, fibrosis stage, HCV genotype & resistance testing (population-based) data, viral RNA levels, demographic data as well as on Rx response, SVR4, and SVR12 were collected and reported.

Results: In 2014, 15 pts with genotype 1 and prior PI experience initiated Rx because of clinical need with 12 wks SOF+SMV with (10) or without (5) RBV . Median age was 61 yrs (range 26-73), baseline HCV RNA 6.5 log IU/ml (5.5-7.0 log), 12 were male, and 10 had cirrhosis. PI Rx occurred 26 (5-85) months prior and included telaprevir (10), boceprevir (3), ABT 450/r (1), GS9451 (1) as part of Rx regimen with 11 nonresponders, 1 relapser, and 3 intolerant of Rx. All had genotype and resistance testing performed prior to SOF+SMV+/-RBV. Of the 9 G1a pts, Q80K was detected in 4, Q80L in1. Of the 6 G1b pts, V36I and T54S were detected in 1 pt each. No other mutations associated with PI resistance were detected.

Responses to SOF+SMV+/-RBV are shown in the table.

	Wk 4 on Rx	End of Rx	Wk 4 post Rx (SVR 4)	Wk 12 post Rx (SVR12)
# completing time point	15	15	14 (1 pending)	13 (2 pending)
# (%) suppressed below quantification (<15 or <43 IU/ml)	15 (100%)	15 (100%)	13 (93%)	12 (92%)
# (%) suppressed below detection	9 (56%)	15 (100%)	13 (93%)	12 (92%)
# relapse (%)			1* (7%)	1* (8%)

*The pt with relapse received SOF+SMV+RBV, had G1b, cirrhosis and a prior history of telaprevir-based Rx completed 14 months prior, and had no known mutations associated with resistance.

Conclusions: Conclusion: SOF+SMV+/-RBV treatment may be appropriate for carefully selected PI-experienced G1 pts including those with cirrhosis. Further study is needed to confirm these findings.

746 Cumulative HIV Care Measures Highly Associated With Acute Myocardial Infarction

Jorge L. Salinas[1]; Christopher T. Rentsch[2]; Vincent C. Marconi[1]; Janet Tate[3]; Adeel A. Butt[4]; Matthew S. Freiberg[4]; Matthew B. Goetz[5]; Maria Rodriguez-Barradas[6]; Amy Justice[3]; David Rimland[1]

[1]Emory University, Atlanta, GA, US; [2]Atlanta VA Hospital, Decatur, GA, US; [3]Yale University, New Haven, CT, US; [4]University of Pittsburgh, Pittsburgh, PA, US; [5]David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA, US; [6]Baylor College of Medicine, Houston, TX, US

Background: After accounting for established risk factors, people living with HIV (PLWHIV) have a 50-75% greater risk of acute myocardial infarction (AMI) than uninfected individuals. Several underlying causes for this association have been suggested including ongoing chronic inflammation, immune suppression, and a greater burden of anemia, renal disease, liver disease, and hepatitis C infection. While many of these factors have been studied in a cross-sectional manner, few have considered the association of cumulative HIV care measures with AMI among PLWHIV. We hypothesized that measuring these factors in a cumulative way would be associated with AMI incidence.

Methods: Retrospective cohort study including PLWHIV starting antiretroviral therapy (ART) in the Veterans Aging Cohort Study Virtual Cohort (VACS VC) from 2000-2009. The impact of baseline, time-updated and cumulative measures of HIV viremia, CD4 count and the VACS Index were modeled. Cumulative measures were captured starting 6 months after ART initiation until AMI event, death, last clinic visit or censor date (December 31, 2009) and calculated as follows:

1) Copy Years viremia (CYV)= Area under the curve of HIV viral load (VL) measures.

2) CD4 Years (CD4Y)= Area under the curve of CD4 measures.

3) VACS Index years (VISY)= Area under the VACS Index curve.

Areas under the curve were calculated using the trapezoidal rule. The VACS Index score was calculated using age, HIV-1 RNA, CD4, aspartate and alanine transaminases, hemoglobin, platelet count, creatinine and known hepatitis C infection. An online calculator is available (http://vacs.med.yale.edu). The primary outcome was incident AMI determined using Medicare and VA ICD9 codes. Multi-variable proportional hazard (PH) models were fit for time to AMI.

Results: 12,131 patients were included in the analysis. Separate PH models were fit for different measures of VL, CD4 and the VACS Index (basal, time-updated and cumulative) and results are presented in table 1. While all three cumulative measures predicted the studied outcome, VCY≥63, 000 copy-years/mL (HR=4.17; 95%CI=3.59-4.85) and CD4Y<750 cell-years/mm^3 (HR=5.61; 95%CI=4.56-6.90); patients with higher VACS Index score-years had the highest risk of AMI (VISY≥250; HR=40.56; 95%CI=33.25-49.47).

HIV viral load measures				CD4 measures				VACS Index measures			
	Person-years	AMIs	Adjusted HR*		Person-years	AMIs	Adjusted HR**		Person-years	AMIs	Unadjusted HR***
Baseline VL (copies/mL)				Baseline CD4 (cells/ mm^3)				Baseline VACS Index score			
<75,000	23,301	84	1	<200	22,582	80	1.45 (1.30-1.61)	<50	25,827	77	1

Abbreviations: AMI: Acute myocardial infarction; HR: Hazard ratio; VL: Viral load; VCY: Viremia copy-years; VACS: Veterans Aging Cohort Study											
*Adjusted for age and baseline CD4 count **Adjusted for age and baseline HIV viral load ***The VACS Index includes age, VL, CD4, aspartate and alanine transaminases (AST, ALT), hemoglobin, platelets, creatinine and hepatitis C infection											

Table 1. Multivariable Cox Proportional Hazards analyses of factors associated with time to Acute Myocardial Infarction among patients starting Initial ART regimens in the VACS Virtual Cohort; 2000-2009.

Conclusions: Cumulative measures of viral load, CD4 count and VACS Index provide added information about risk of AMI, of these, VACS Index is the most comprehensive.

747 Cardiovascular Disease Risk Prediction in the HIV Outpatient Study (HOPS)

Angela M. Thompson-Paul[1]; **Kenneth A. Lichtenstein**[2]; Carl Armon[3]; Kate Buchacz[1]; Rachel Debes[3]; Joan S. Chmiel[4]; Frank J. Palella[4]; Stanley C. Wei[1]; Jacek Skarbinski[1]; John T. Brooks[1]

[1]US Centers for Disease Control and Prevention, Atlanta, GA, US; [2]National Jewish Health, Denver, CO, US; [3]Cerner Corporation, Vienna, VA, US; [4]Northwestern University, Feinberg School of Medicine, Chicago, IL, US

Background: HIV infection is associated with an increased risk of cardiovascular disease (CVD); however, it is unknown if commonly used CVD risk prediction tools accurately predict risk in HIV-infected persons. In this analysis, we examined four CVD risk prediction equations to determine if they accurately estimate events and predict risk events in a large diverse cohort of HIV-infected adults in the United States.

Methods: We analyzed longitudinal data on HIV Outpatient Study (HOPS) participants in care at 10 U.S. clinic sites as of 30 September 2013 who met the following criteria: had at least one year of follow-up after 1 January 2002, enrolled in the HOPS no later than 1 October 2010, had at least one total cholesterol measurement, and at least two systolic blood pressure measurements at baseline. We applied four CVD risk equations to the HOPS data to estimate 10-year CVD risk, and using Harrell's *C*-statistic assessed their predictive ability to discriminate patients who did vs. did not experience incident CVD events. Incident CVD events were defined for each risk equation are as follows: 1) Framingham Point Score (FPS)– myocardial infarction (MI), fatal coronary heart disease (CHD), stroke; 2) Pooled Cohort Equation (PCE) - MI, stroke, coronary artery disease (CAD); 3) Systematic COronary Risk Evaluation (SCORE) for low-risk populations – fatal MI, stroke, peripheral vascular disease, CAD; and 4) the Data Collection on Adverse Effects of Anti-HIV Drugs (D:A:D) study equations - MI, sudden death, CAD, stroke, and death from other CHD.

Results: There were 2392 participants with a median age of 43 years; 76% were male, 50% were non-Hispanic white, and 87% were antiretroviral experienced at baseline. Common co-morbid conditions included hypertension (50%), diabetes (10%), and high cholesterol (17%). In this cohort, 204 incident CVD events occurred during a median follow-up time of 6.5 years. All equations underestimated 10-year CVD risk to a variable degree (Table 1). The FPS, PCE, and D:A:D equations showed moderate discrimination (C-statistic range, 0.68 to 0.72), whereas SCORE showed poor discrimination (C-statistic=0.59).

HOPS participants (n=2,392)	10-Year CVD Risk Estimation			
	FPS	PCE	SCORE	D:A:D
C-statistic*	0.71	0.71	0.57	0.72
Expected events (E)	126	147	19	193
Observed events (O)	149	178	23	256
Ratio E/O	0.85	0.83	0.83	0.75
p-value	0.002	<0.001	0.02	<0.001
Abbreviations: FPS, Framingham Point Score; PCE, Pooled Cohort Equation; SCORE, Systematic COronary Risk Evaluation; D:A:D, Data Collection on Adverse Effects of Anti-HIV Drugs. * Harrell's C-statistic assessed the ability of each prediction model to discriminate patients who did vs. did not experience incident CVD events.				

Comparison of 10-year cardiovascular disease (CVD) risk estimation and discrimination in four CVD risk calculators in HIV-infected adults from the HIV Outpatient Study (HOPS).

Conclusions: The four risk prediction equations underestimated the 10-year risk of CVD in our large, diverse cohort of HIV-infected adults. To better estimate CVD risk in HIV-infected persons in the U.S., additional risk factors, such as immunologic or virologic status may need to be considered.

748 Incidence and Risk of Myocardial Infarction (MI) by Type in the NA-ACCORD

Daniel R. Drozd[1]; Mari M. Kitahata[1]; Keri N. Althoff[2]; Jinbing Zhang[2]; Susan R. Heckbert[1]; Matthew J. Budoff[3]; Frank J. Palella[4]; Daniel B. Klein[5]; Richard D. Moore[6]; Heidi M. Crane[1]

[1]University of Washington, Seattle, WA, US; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [3]University of California Los Angeles, Los Angeles, CA, US; [4]Northwestern University, Chicago, IL, US; [5]Kaiser Permanente Northern California, Hayward, CA, US; [6]Johns Hopkins University, Baltimore, MD, US

Background: HIV-infected persons may be at increased risk for cardiovascular disease (CVD) and MI, but the role of HIV in the pathogenesis of MI is unclear. The Universal Definition of MI (UDMI) classifies MIs by underlying pathophysiology into classic *primary* (type 1) MIs due to atherothrombotic coronary plaque rupture and *secondary* (type 2) MIs resulting from supply-demand mismatch caused by a heterogeneous set of clinical conditions including sepsis and cocaine-induced vasospasm. In the general population, primary MIs are more common than secondary MIs. Prior studies in HIV have not classified the type of MI and therefore, have examined primary and secondary MIs as a single endpoint, which may limit their ability to define the contribution of HIV to CVD and primary MI risk. We determined the incidence of adjudicated primary MIs distinct from secondary MIs and examined baseline risk factors for primary MIs.

Methods: MIs were centrally adjudicated in 7 NA-ACCORD clinical cohorts between 1996-2010 in patients who screened positive and classified according to the UDMI; primary events included invasive cardiac interventions (CABG, stent placement). Incidence rates (IRs) per 1,000 person-years (PY), adjusted incidence rate ratios (aIRRs), and 95% confidence intervals ([,]) were estimated using Poisson regression adjusted at baseline for sex, race/ethnicity, HIV risk group, year of enrollment, cohort, ever smoked, hypertension (HTN), diabetes (DM), dyslipidemia, chronic kidney disease (CKD), CD4 count, and HIV RNA (viral load); age was time-updated.

Results: There were 24,919 patients who experienced 262 primary and 205 secondary MIs in 95,728 PYs of follow-up: primary MI IR=2.74 [2.42, 3.09] and secondary MI IR=2.14 [1.87, 2.46]. Significant predictors of primary MI included age, HTN, DM, dyslipidemia, smoking, stage 4/5 CKD, and CD4 count (Table 1). Sepsis (33%), cocaine (8%), respiratory failure (5%), and hypertensive emergency (4%) combined accounted for 50% of all secondary MIs.

Table 1. Adjusted rate ratios (aIRR) and 95% confidence intervals for primary MI

	aIRR [95% CI]
Age	
<40	1.00
40-49	**3.42 [2.06, 5.68]**
50-59	**5.14 [3.05, 8.66]**
60-69	**9.96 [5.66, 17.53]**
Hypertension	**1.92 [1.45, 2.55]**
Diabetes mellitus	**2.01 [1.39, 2.89]**
Ever smoker	**2.02 [1.38, 2.94]**
Dyslipidemia	**1.75 [1.32, 2.32]**
Stage 4/5 CKD	**7.73 [3.05, 19.59]**
CD4 (cells/mL)	
<200	1.00
200-349	**0.63 [0.44, 0.90]**
≥350	**0.66 [0.49, 0.88]**
HIV viral load (copies/mL)	
<200	1.00
201-9,999	1.23 [0.88, 1.71]
10,000-99,999	**1.54 [1.06, 2.24]**
≥100,000	1.17 [0.71, 1.92]

Conclusions: Traditional CVD risk factors and immunosuppression significantly predict primary MIs. The high rate of secondary MIs emphasizes the need for greater clarity in outcome ascertainment in studies seeking to study the pathogenic role of HIV in CVD. Future analyses will examine the complex longitudinal relationship between primary MIs and HIV-specific factors including CD4 count, viral load, and ART.

750 HIV-Infected Veterans and the New ACC/AHA Cholesterol Guidelines: Got Statins?

Meredith E. Clement[1]; Lawrence Park[1]; Ann Marie Navar-Boggan[1]; Nwora L. Okeke[1]; Michael Pencina[1]; Pamela Douglas[1]; Susanna Naggie[1]

[1]Duke University, Durham, NC, US; [2]Duke University, Durham, NC, US; [3]Duke University, Durham, NC, US

Background: Cardiovascular disease, an HIV-associated non-AIDS related (HANA) condition, is an emerging threat to people living with HIV; thus, appropriate primary and secondary prevention is critical. In November 2013 updated guidelines for cholesterol treatment from the American College of Cardiology and the American Heart Association (ACC/AHA) substantially expanded recommendations for statin use among the general population for cardiovascular disease (CVD) prevention compared to the prior Adult Treatment Panel (ATP-III) guidelines. How these new recommendations impact adults with HIV-infection is unknown.

Methods: We used the Veterans Affairs (VA) Clinical Case Registry (CCR), one of the largest clinical databases of HIV-infected patients worldwide, to determine the impact of the new the new cholesterol guidelines on statin recommendations for HIV-infected veterans. Electronically available laboratory, medication, and comorbidity data from 2008 to 2010 were used to assess statin recommendations under the ATP-III and the 2013 AHA/ACC guidelines among male patients aged 40 to 75 years. Descriptive statistics are presented comparing the proportion of adults recommended under each guideline.

Results: 13293 male veterans with HIV-infection met inclusion criteria for the analysis. The average age was 54.6 years. Cardiovascular disease was present in 8.2% and diabetes in 15.4%. Of 13293 veterans, 5185 (39.0%) had been prescribed statin therapy (32.2% for primary prevention and 6.8% for secondary prevention). Overall, 11.6% of adults not previously eligible for statin therapy under ATP-III were newly recommended under ACC/AHA guidelines, with 7085 (53.3%) veterans recommended for statin therapy under the ATP-III guidelines compared to 8630 (64.9%) under the ACC/AHA guidelines. The majority of the increase in statin eligibility was in adults recommended for primary prevention; with 9.1% newly recommended based on 10-year risk score, 1.7% newly recommended based on diabetes, and 0.8% newly recommended based on presence of CVD.

	ATP-III	ACC/AHA
Already on Statin		
Primary prevention	4286 (32.2%)	4286 (32.2%)
Secondary prevention (CVD)	899 (6.8%)	899 (6.8%)
Subtotal	**5185 (39.0%)**	**5185 (39.0%)**
New Statin Recommended		
Primary prevention	1803 (13.5%)	3244 (24.4%)
LDL>190	70 (0.5%)	70 (0.5%)
Diabetes	248 (1.9%)	475 (3.6%)
10-yr Risk Score	1485 (11.2%)	2699 (20.3%)
Secondary Prevention (CVD)	97 (0.7%)	201 (1.5%)
Subtotal	**1900 (14.3%)**	**3445 (25.9%)**
No Statin Recommended		
Primary prevention	6104 (45.9%)	4663 (35.1%)
Diabetes	384 (2.9%)	157 (1.2%)
10-yr Risk Score	5720 (43.0%)	4506 (33.9%)
Secondary Prevention	104 (0.8%)	0
Subtotal	**6208 (46.7%)**	**4663 (35.1%)**
Total	**13293 (100%)**	**13293 (100%)**

Conclusions: In our study population of HIV-infected veterans, application of the new ACC/AHA cholesterol guidelines resulted in an approximate 12% absolute increase in the proportion of patients for whom statin therapy is indicated. The increased recommended use of statins is primarily related to risk assessed by the 10-year risk score of cardiovascular disease. It will be important to assess the benefit of this expanded prevention measure prospectively.

751 Evaluation of the ACC/AHA CVD Risk Prediction Algorithm Among HIV-Infected Patients

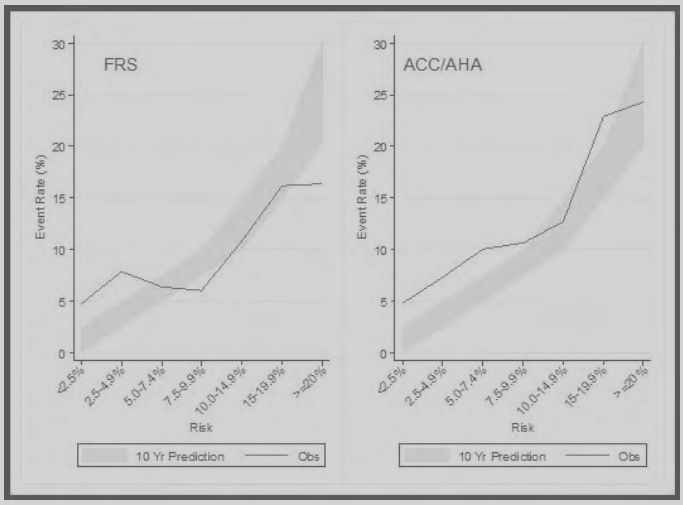
Susan Regan[2]; James B. Meigs[2]; Joseph Massaro[3]; Ralph B. D'Agostino[3]; Steven Grinspoon[2]; **Virginia A. Triant**[2]

[1]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [3]Boston University, Boston, MA, US; [4]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US

Background: The 2013 American College of Cardiology (ACC)/ American Heart Association (AHA) cardiovascular disease (CVD) risk prediction algorithm (Pooled Cohorts Equations) has not previously been evaluated in HIV populations.

Methods: Framingham Risk Scores (FRS) and ACC/AHA risk scores were calculated for patients in a longitudinal HIV clinical care cohort during a 3-year interval ending January 1, 2009. Patients were not eligible if they were under age 18, had expired prior to January 1, 2009, were missing relevant data to populate the risk score, or had undergone a relevant outcome event prior to the date of risk score calculation. CVD risk was considered high if 10-year predicted risk of the relevant outcome event was ≥10 percent for FRS and ≥7.5 percent for ACC/AHA. Outcome events were coronary heart disease (CHD) for FRS and atherosclerotic CVD (ASCVD) for ACC/AHA.

Results: The FRS was calculated for 2270 patients, with a median follow-up time of 6.3 years, and the ACC/AHA risk score was calculated for 2152 patients, with a median follow-up time of 6.2 years. Risk scores were discordant in 17 percent of patients, with the ACC/AHA score only predicting high risk in 10 percent and the FRS only predicting high risk in 7 percent. In comparisons of these discordant subgroups, patients classified as high-risk by ACC/AHA but low-risk by FRS were older (median age 56 for ACC/AHA high vs. 48 for FRS high) and more likely to be female (68% vs. 0%), diabetic (52% vs. 6%) and black (22% vs. 12%) but less likely to be smokers (44% vs. 66%) than those low-risk by ACC/AHA and high-risk by FRS. Actual event rates were estimated and compared with predicted rates. As shown in the figure, actual 6-year event rates were similar to 10-year predicted rates for the FRS and were similar to or exceeded predicted rates for the ACC/AHA risk score.



Conclusions: Our findings suggest that CVD risk prediction scores designed for the general population, and particularly the new ACC/AHA risk score, may underestimate risk for HIV-infected patients. Accurate CVD risk prediction is an important component of the long-term management of chronic disease complications in HIV.

863 Specific Effects of ZDV, 3TC and LPV/r on HIV-1 RNA Viral Load During Pregnancy

Patumrat Sripan[1]; Sophie Le Coeur[5]; Lily Ingsrisawang[2]; Tim R. Cressey[3]; Jean-Marc Tréluyer[6]; Naïm Bouazza[4]; Frantz Foissac[4]; Gonzague Jourdain[3]; Marc G. Lallemant[3]; Saïk Urien[7]

Background: HIV-infected women commonly receive zidovudine (ZDV) + lamivudine (3TC) + lopinavir/ritonavir (LPV/r) during pregnancy for the prevention of mother-to-child transmission (PMTCT) in Thailand. Our aims were to evaluate the role of 3TC added to ZDV+LPV/r and the specific effect of each drug on maternal HIV-1RNA viral load (VL) reduction for the PMTCT.

Methods: A total of 1,655 plasma VL levels from 702 pregnant women enrolled in the PHPT-5 perinatal HIV prevention trial in Thailand (NCT01511237, NCT00409591) were included. ART naïve pregnant women received either (1) ZDV only (plus nevirapine at onset of labor); (2) ZDV+LPV/r; or (3) ZDV+3TC+LPV/r. HIV-1 RNA VL time courses were analysed using non-linear mixed effect modelling and dependent on VL at treatment initiation and duration of treatments. An Emax response model was used to describe the impact of these ARV regimens on VL reduction during pregnancy. A mechanistically-based equation was developed to determine the contribution of each drug assuming ZDV and 3TC have the same target and mechanism of action, and the effect of LPV/r was added as a separate component.

Results: Of the 702 women, 278 (40%) received ZDV monotherapy, 146 (20%) ZDV+LPV/r and 278 (40%) ZDV+3TC+LPV/r during pregnancy. The maximum effect of each regimen on HIV-1 RNA VL was significantly different ($p<0.02$), with 1.67, 3.8 and 4.57 log_{10}copies/mL reduction for ZDV alone, ZDV+LPV/r and ZDV+3TC+LPV/r, respectively. Time to reach half of maximum effect (T_{50}) was significantly longer with ZDV alone compared with ZDV+3TC+LPV/r ($p<0.001$). However there was no significant difference between ZDV+LPV/r and ZDV+3TC+LPV/r ($p=0.13$). The mechanistically-based model estimated that 110 days of ZDV or 3TC were necessary to achieve half of ZDV or 3TC maximum effect on viral load suppression (maximum effect: minus 1.38 and 2.05 log_{10}copies/mL, respectively) whereas only 10 days of LPV/r were necessary to achieve half of LPV/r maximum effect (maximum effect: minus 2.32 log_{10} copies/mL). Using the mean VL at treatment initiation (4.07 log_{10} copies/mL), the model indicated that the addition of 3TC reduced the time to undetectable VL (<50copies/mL) by 3 weeks: 7.3 weeks with ZDV+LPV/r compared with 4.4 weeks for ZDV+3TC+LPV/r assuming a common T_{50} for ZDV and 3TC.

Conclusions: The addition of 3TC to ZDV+LPV/r during pregnancy reduces time to reach undetectable VL in pregnant women, especially those with a high VL at treatment initiation and subsequent high risk of MTCT.

864 Viral Suppression After Antiretroviral Therapy Initiation in Pregnancy in South Africa

Landon Myer[1]; Tamsin Phillips[1]; Nei-Yuan Hsiao[2]; Allison Zerbe[3]; Jo Ramjith[1]; Linda-Gail Bekker[1]; James A. McIntyre[4]; Elaine J. Abrams[3]

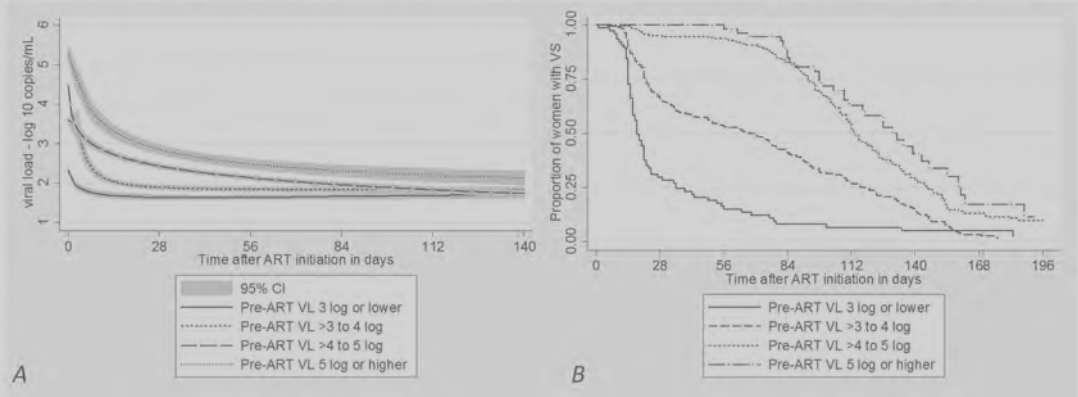
[1]University of Cape Town, Cape Town, South Africa; [2]National Health Laboratory Services/University of Cape Town, Cape Town, South Africa; [3]ICAP at Columbia University, New York, NY, US; [4]Anova Health Institute, Johannesburg, South Africa

Background: HIV viral load (VL) is the principle determinant of mother-to-child transmission (MTCT) risk and rapid lowering of VL is a primary goal of antiretroviral therapy (ART) for prevention of MTCT. However there are few data on the trajectory of viral load (VL) and time to viral suppression <50 copies/mL (VS) following ART initiation in HIV-infected pregnant women.

Methods: Consecutive pregnant women initiating ART in Cape Town, South Africa were recruited into a prospective cohort from ART initiation through delivery, with VL measured immediately prior to initiation (pre-ART), 1-4 weeks after initiation, during the 3rd trimester, and at 1 week postpartum. All women initiated TDF+FTC+EFV. Analyses examined changes in log VL trajectories after initiation using non-linear mixed models, the proportions of women achieving VS over time using product-limit methods, and the probability of VS at delivery using logistic regression.

Results: From April 2013 to May 2014, 629 ART-naïve pregnant women were enrolled (median age, 28 years; median CD4 cell count, 343 cells/μL; median gestation age (GA), 21 weeks; median VL, 4.0 log10 copies/mL [IQR: 3.4-4.6]). Most women achieved VL<3 log within 4 weeks of ART start (Figure 1a) but the median time to VS<50 copies/mL was 14.1 weeks (95% CI, 13.3-15.3). Time to VS was strongly influenced by pre-ART VL: women with VL <3, 3-4, 4-5 and >5 log10 copies/mL before ART initiation had median times to VS of 2.9, 9.6, 17 and 18.9 weeks, respectively ($p<0.001$; Figure 1b). 75% of women achieved VS by delivery. Adjusting for age and past ARV exposure, decreased probability of VS at delivery was associated with higher pre-ART VL (relative odds [RO] 0.39 for a 1-log increase in pre-ART VL, $p<0.001$); later GA at ART initiation (RO, 0.87 for a 1-week increase in GA at ART initiation, $p<0.001$); and inversely associated with higher pre-ART CD4 cell counts (RO, 1.08 for a 50-unit increase in pre-ART CD4 cell count, $p=0.025$).

Figure 1. Viral load declines following ART initiation in pregnancy: (a) fractional polynomial modelling of VL declines over time and (b) time to viral suppression <50 copies/mL, by pre-ART VL categories



Conclusions: These data provide novel evidence on VS after ART initiation in pregnancy in African populations using a standardised first-line regimen. The rapid early declines in VL to <3 log within a month on ART in most women are encouraging. However one-quarter of the cohort still had detectable VL at the time of delivery, demonstrating the importance of early initiation of ART in pregnancy.

865 Maternal Viral Load in the Context of PMTCT B+ Within the Kabeho Study in Kigali

Emily A. Bobrow[1]; Placidie Mugwaneza[2]; Gilles F. Ndayisaba[3]; Dieudonne Ndatimana[3]; **Michelle Gill**[1]; Heather J. Hoffman[4]; Cyprien Baribwira[5]; Laura Guay[1]; Anita Asiimwe[6]
Kabeho Study Team

[1]Elizabeth Glaser Pediatric AIDS Foundation, Washington, DC, US; [2]Ministry of Health, Kigali, Rwanda; [3]Elizabeth Glaser Pediatric AIDS Foundation, Kigali, Rwanda; [4]George Washington University Milken Institute School of Public Health, Washington, DC, US; [5]University of Maryland, School of Medicine, Kigali, Rwanda; [6]Rwanda University Teaching Hospitals, Kigali, Rwanda

Background: In April 2012, Rwanda started to implement a policy to initiate HIV-positive pregnant women on lifelong antiretroviral treatment (ART) ('Option B+'). In April 2013, EGPAF and the Ministry of Health began the Kigali Antiretroviral and Breastfeeding Assessment for the Elimination of HIV (Kabeho) Study. The study will determine 18 and 24 month HIV-free survival of a cohort of HIV-exposed children in the PMTCT program.

Methods: From April 2013-January 2014, 608 HIV-positive women on triple drug ART in the third trimester of pregnancy or within two weeks post-delivery were enrolled in the observational prospective cohort from 14 health facilities in Kigali. After providing written informed consent, women underwent enrollment, including HIV and ART-related history and adherence, and a blood draw for viral load (VL) testing by RNA-PCR (Roche).

Results: The median time women knew their HIV-positive status was 38.0 months (IQR 4.7–83.5). The most common ARV regimen (56.6%, 344/608) was TDF/3TC/EFV. Overall, 35.2% (n=214) of women reported taking another regimen previously; 21.5% (n=130) due to PMTCT during an earlier pregnancy. At enrollment, women were on ART for a median of 13.4 months (IQR 2.96–48.8); median time on current ART was 9.2 months (IQR 2.3-34.8). The adherence rate based on a 3-day ART recall was 90.9%. Side effects were reported in the past month by 17.5% (n=105) of women, with dizziness as most common (n=53).

Half of women (52.2%, 316/606) had undetectable VL. Figure 1 shows the distribution of VL by ART duration. Logistic regression using GEE (N=579) indicates women were more likely to have a detectable VL if they had no education (AOR=2.21, 95% CI: 1.31, 3.73), reported side effects in the past month (AOR=1.96, 95% CI: 1.37, 2.81), and had been on ART less than four months, when compared to those with ART exposure from 4-12 months (AOR=3.98, 95% CI: 2.11, 7.50), 12-24 months (AOR=6.04, 95% CI: 2.47, 14.76), and 24-36 months (AOR=5.57, 95% CI: 2.38, 13.05). VL slightly decreased beyond 36 months on ART (AOR=3.56, 95% CI: 1.69, 7.50).

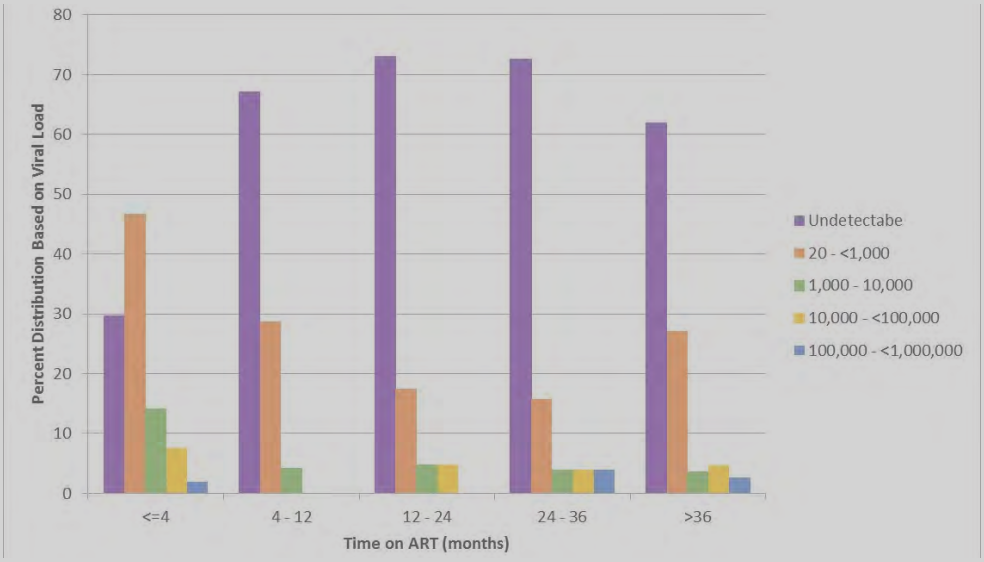


Figure 1. Distribution of viral loads stratified by time on ART.

Conclusions: High rates of ART adherence in the antenatal/peripartum period under Option B+ were reported. However, only half of women had undetectable VL at enrollment. Findings suggest longer ART duration may be needed for women in PMTCT to achieve viral suppression. Testing for ARV resistance is planned. Analysis of the cohort will incorporate specific regimen information, regimen changes, longitudinal VL, and adherence over time.

866 ART Response Among Pregnant and Postpartum Women With Acute Versus Chronic HIV-1

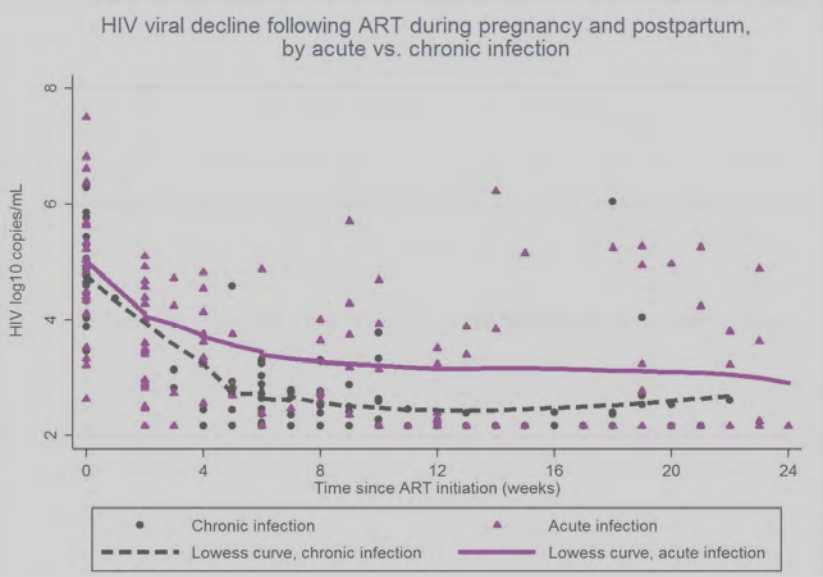
Alison L. Drake[1]; John Kinuthia[2]; Daniel Matemo[2]; Barbra Richardson[1]; Michael Chung[1]; James N. Kiarie[2]; Sandy Emery[3]; Julie M. Overbaugh[3]; Grace John-Stewart[1]

[1]University of Washington, Seattle, WA, US; [2]University of Nairobi, Nairobi, Kenya; [3]Fred Hutchinson Cancer Research Center, Seattle, WA, US

Background: Risk of mother-to-child HIV-1 transmission (MTCT) is high among women with acute HIV-1 infection (AHI). Plasma HIV-1 viral load (PVL) can be substantially reduced with antiretroviral therapy (ART), which reduces MTCT risk; however, viral decline post-ART among pregnant and postpartum women with AHI has not been well characterized. We compared virologic and immunologic responses to ART between pregnant and postpartum women with AHI versus chronic HIV-1 infection (CHI) in Kenya.

Methods: Women with AHI (detected by nucleic acid amplification tests conducted serially during pregnancy and postpartum) initiating ART (3TC, EFV, and either ZDV or TDF) were identified in a prospective study in Western Kenya. Women with CHI who initiated ART (AZT, 3TC, and NVP) during pregnancy in a prior clinical trial in Nairobi and had available PVL and CD4 data were selected for comparison. Blood was collected serially in both studies to compare post-ART changes in PVL and CD4; PVL was evaluated using the same laboratory and assay for both studies. Linear mixed effects models were used to model rate of PVL decline and demographics and CD4 were compared by the Wilcoxon Rank-Sum Test.

Results: Data from 25 women with AHI and 30 women with CHI were compared. Women with AHI were younger (median 21 vs. 30 years; p=.006) and less likely to be married (97% vs. 76%; p=.02) than women with CHI. Mean baseline PVL was similar (AHI: 4.52, CHI: 4.37 $\log_{10}$copies/mL; p=.5). Baseline CD4 count was significantly higher in women with AHI than CHI (median 542 vs. 267, respectively; p<.001). Average monthly decline in PVL during 10 weeks post-ART was greater among women with CHI (-1.04 $\log_{10}$ copies/mL; 95% Confidence Interval [CI]:-1.50,-0.57) than AHI (-.67 $\log_{10}$copies/mL, 95% CI:-0.84, -0.47); CHI versus AHI PVL decline p=.007), adjusting for baseline CD4. Viral decline was less pronounced 10 to 24 weeks post-ART in both groups, but remained steeper among women with CHI versus AHI (-.15 versus -.03 $\log_{10}$copies/mL, respectively; p=.002). Change in CD4 counts 6 months post-ART was similar (p=.5).



Conclusions: Rate of viral decline following ART was significantly slower among women with AHI than CHI, perhaps because HIV-specific immune responses that work synergistically with ART to decrease PVL have not yet developed in AHI. Strategies to accelerate viral decline, such as ART-intensification among AHI during pregnancy and postpartum, may be useful to reduce MTCT risk.

959 Tenofovir/Emtricitabine Plus LPV/r vs MVC or Raltegravir for PEP: 2 Randomized Trials

Lorna Leal; Agathe Leon; Berta Torres; Alexy Inciarte; Constanza Lucero; Josep Mallolas; Maria Martinez-Rebollar; Ana González-Cordón; Jose M. Gatell; Felipe Garcia

Hospital Clínic Barcelona, Barcelona, Spain

Background: PEP is recommended after a potential exposure to HIV. In animal models, PEP has to be maintained 4 weeks to be effective. However, with the recommended regimens in humans, side effects are frequent and are the main reason for poor adherence and a high rate of discontinuation. The objective of these 2 trials was to assess the rate of discontinuation of PEP at 28 days comparing the standard of care Lopinavir/r (LPV/r) vs Maraviroc (MVC) or Raltegravir (RAL) both with Tenofovir/Emtricitabine (TVD).

Methods: Individuals coming to the emergency room (ER) for potential sexual exposure to HIV were randomized to: TVD 200/245 QD plus LPV/r 400/100 BID (n=117) or plus MVC 300 BID (n=120) in one trial (n=237) and TVD plus LPV/r (n=121) or plus RAL 400 BID (n=122) in the second trial (n=243). After randomization, 4 follow-up visits were scheduled: day 0, 28, 90 and 180. The primary end-point was rate of discontinuation at day 28. Secondary end-points were adherence to PEP, side effects and rate of seroconversions.

Results: In MVC and RAL trials, median age was 35 and 33 years and 92% and 90% were males respectively. The median interval between exposure and presentation at ER was 15h and 13.5h. Type of exposition was male homosexual sex in 83% and 81%. The level of risk was high in only 13% and 9% of individuals. The source patient was known to be HIV infected in 30.8% and 31%. In MVC trial, only 187/237 (79%) who were randomized and started PEP attended the first scheduled visit (day 0) and differences between arms were not observed (p=0.92). Similar results were found in RAL trial [198/243 (81.5%) attended the day 0 (p=0.62)]. The rate of discontinuation of PEP before day 28 of follow-up was significantly higher in LPV/r (31.5%) vs MVC (11.6%) arm (p=0.001) and in LPV/r (36.6%) vs RAL (23.7%) arm (p=0.04). The proportion of patients with low adherence to PEP was similar in LPV/r vs MVC arms (54% vs 46%, respectively, p=0.56), but was higher in LPV/r vs RAL arms (49.2% vs 30.8%, respectively, p=0.03). Adverse effects were reported in 122 out of 187 (50.8%) patients in MVC study attending at least the day 0 visit [70/92 (76.1%) in LPV/r and 52/95 (54.7%) in MVC arm, p=0.002] and in in 134 out of 198 (67.7%) patients in RAL study [75/101 (74.3%) in LPV/r and 59/97 (60.8%) in RAL arm, p=0.04]. No seroconversions were observed.

Conclusions: The rate of discontinuation of PEP and side effects were higher in patients allocated to TVD plus LPV/r as compared with those with TVD plus MVC or TVD plus RAL.

958 Rilpivirine-Emtricitabine-Tenofovir for HIV Nonoccupational Postexposure Prophylaxis

Rosalind Foster[1]; John McAllister[2]; Tim R. Read[3]; Anna Pierce[4]; Robyn Richardson[2]; Anna McNulty[1]; Andrew Carr[2]
On behalf of the EPEP Study Researchers

[1]*Sydney Sexual Health Centre, Sydney, Australia;* [2]*St Vincent's Centre for Applied Medical Research, Sydney, Australia;* [3]*Melbourne Sexual Health Centre, Melbourne, Australia;* [4]*The Alfred Hospital, Melbourne, Australia*

Background: CDC recommends 3-drug post-exposure prophylaxis (PEP) with emtricitabine-tenofovir disoproxil fumarate (FTC-TDF) plus raltegravir (RAL) for 28 days. But in one non-occupational (N)PEP study, FTC-TDF-RAL adherence was imperfect (only 52% took all 3 pills/day) and RAL was associated with acute muscle adverse effects (9%). FTC-TDF coformulated with rilpivirine (RPV) as a single-tablet regimen (STR) is a well-tolerated, once-daily NPEP candidate. A plasma tenofovir (TFV) level >40ng/mL is thought to reflect recent full adherence, whereas a level <10ng/mL suggests no dose for ≥7 days. NPEP studies to date have neither evaluated STRs nor measured TFV levels. We hypothesized FTC/RPV/TDF as an STR NPEP would be safe, well-tolerated, and result in high adherence.

Methods: We evaluated NPEP with STR FTC/RPV/TDF for 28 days in gay men after high-risk, sexual exposure, in an open-label, single-arm study. We assessed adherence (pill count; patient report; and plasma TFV levels at Week 4 in a subset by HPLC), adverse events (AEs) and HIV status through Week 12. Final intention-to-treat (ITT) analyses are reported.

Results: 100 men (mean age 31 years [SD 9]) presented a mean 30 hours (SD 21) after anal sex (88% receptive). NPEP commenced 2 hours (SD 2.3) post-presentation. No participant was HIV+ at enrolment or through Week 12, or ceased NPEP because their 'source' was found to be HIV-negative. NPEP completion was 92% (95%CI 85 to 96); failures occurred at median 14 days for loss to follow-up (6%), adverse event (1%) or study burden (1%). NPEP adherence was 98.6% (SD 2.7) by self-report. In the 78 participants with pill-count data, adherence was 98.7% (SD 2.4). 86% reported taking all doses with food. Of 78 paired assessments available for percent adherence by pill count and self-report, agreement was 100% (kappa=1.0; P<0.0001). From the final 50 participants, plasma TFV was measured within 48 hours of the last dose in 41 (88%) participants who reached Day 28 (mean 16 hrs [SD 10]): 36 (88%) participants had levels >40ng/mL and only 1 (2%) was <10ng/mL. One participant developed pancreatitis 1 day post-NPEP. 5 other participants

developed a Grade 3 AE; 2 possibly due to study drug**.** Grade 3+ lab AEs possibly due to study drug occurred in 2 participants. Mean serum creatinine rose from 83 to 88 μM/L at Day 28 (P<0.001), but with no grade 1+ increase and no significant change in serum phosphate.

Conclusions: STR FTC/RPV/TDF was well-tolerated as once-daily NPEP, with high levels of adherence and completion.

957 Significant Intolerability of Efavirenz in HIV Occupational Postexposure Prophylaxis

Surasak Wiboonchutikul[1]; Varaporn Thientong[1]; Patama Sutha[1]; Boonchai Kowadisaiburana[2]; Weerawat Manosuthi[1]

[1]Bamrasnaradura Infectious Diseases Institute, Nonthaburi, Thailand; [2]Bangkok Hospital, Bangkok, Thailand

Background: Postexposure prophylaxis (PEP) has been used to decrease a risk of HIV transmission after occupational exposure. Regimen completion is one of the most important factors in successful prophylaxis. Limited data are available on tolerability of PEP regimens in healthcare workers (HCWs) in resource-limited settings. We aimed to describe the characteristics of occupational exposure, and sought to determine factors associated with incompletion of the 4-week HIV prophylactic course.

Methods: A retrospective study was conducted among HCWs who accidentally exposed to blood or body fluid of patients at Bamrasnaradura Infectious Diseases Institute, Thailand, between March 1996 and June 2014. The characteristics of exposure were described, and logistic regression analysis was used to determine factors associated with incompletion of the 4-week prophylactic course.

Results: A total of 225 exposure episodes were reported (163 percutaneous injury, 43 mucosal exposure, 6 non-intact skin exposure, and 13 intact skin exposure). The mean (SD) age was 33.1 (9.9) years and 189 (84%) were females. The most frequently exposed groups were nurses (43%), patient or nurse assistants (18%), and medical technicians (15%). The HIV status of the source was defined in 149 (66%) episodes which were positive in 101 (68%). Of 225 exposures, PEP was prescribed in 155 (69%) episodes but was subsequently intentionally discontinued in 26 episodes (HIV source was negative in 19, refusal to continue in 7). PEP courses should have completed in 129 episodes. Of 129 prescribed regimens, 38% were 2 NRTIs, 37% were 2 NRTIs + PIs, 12% were Zidovudine alone, 9% were 2 NRTIs + Efavirenz (EFV), and 4% were 2 NRTIs + Raltegravir. Only 91 of 129 (71%) HCWs were able to complete the 4-week regimen. Multivariate analysis showed that 2 NRTIs + EFV was the only significant factor associated with incompletion of the 4 week-course (OR 33.3; 95% CI 4.2-100; $p < 0.01$). Other factors including age, gender, staff position, status of the source, and other PEP regimens were not associated with incompletion of the 4-week course ($p > 0.05$). The reason for premature discontinuation of 2 NRTIs + EFV was intolerability in all HCWs. None of the HCWs was reported to have HIV seroconversion.

Conclusions: Two NRTIs + EFV regimen was significantly associated with premature discontinuation of occupational PEP. This regimen should not be further used for HIV prophylaxis following occupational exposure in the resource-limited settings.

961 Management of Acute HIV After Initiation of Postexposure Prophylaxis: Challenges and Lessons Learned

Goli Haidari[1]; Naomi Fitzgerald[4]; Sonia Raffe[2]; Nneka Nwokolo[3]; Olamide Dosekun[1]; Mark D. Lawton[5]; Nickie Mackie[1]; Julie Fox[4]; Martin Fisher[2]; Sarah Fidler[1]

[1]St Mary's Hospital–Imperial College Healthcare NHS Trust, London, United Kingdom; [2]Brighton and Sussex Hospitals NHS Trust, Brighton, United Kingdom; [3]Chelsea and Westminster Hospital NHS Foundation Trust, London, United Kingdom; [4]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; [5]The Royal Liverpool and Broadgreen University Hospitals NHS Trust, Liverpool, United Kingdom; [6]St Mary's Hospital–Imperial College Healthcare NHS Trust, London, United Kingdom; [7]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; [8]Brighton and Sussex Hospitals NHS Trust, Brighton, United Kingdom; [9]St Mary's Hospital–Imperial College Healthcare NHS Trust, London, United Kingdom

Background: International guidelines recommend HIV post exposure prophylaxis following sexual exposure (PEPSE) to prevent HIV infection. However, methods to screen for infection prior to initiating PEPSE are less clear, with little or no guidance for management of acute HIV diagnosed during PEPSE. We present a case series of individuals diagnosed HIV+ whilst on PEPSE.

Methods: Cases definitions include the following criteria:

1. PEPSE failure: negative point of care test (POCT) and 4th generation laboratory test at PEP start, with HIV diagnosed during PEP or in follow up period

2. Acute HIV infection at PEPSE initiation: negative POCT but subsequent reactive 4th generation test at PEP start

Results: 18 patients identified; 17 male/1 female, mean age 34 years. 11/18 (67%) had a previous negative HIV test using laboratory Abbott Ab/Ag tests, 1/18 POCT, in the preceding 12 months to accessing PEP. 18/18 were prescribed NRTI + bPI, 16 of these in line with current UK guidelines.

From data available on 16 (2 not diagnosed at our trusts), HIV diagnoses were subsequently made using laboratory Ab/Ag test in 14/16, POCT in 1 and HIV RNA in 1. 1/18 tested negative by POCT and Ab/Ag lab tests at PEP start, subsequently tested HIV+ with a weakly reactive p24 antigen and positive HIV-RNA on laboratory testing 19 days after completing a 28 day PEP course. The remaining 17 patients initiated PEP based on a negative POCT or recent negative HIV antibody test but were subsequently diagnosed HIV+ using lab tests . Therefore 17/18 (94%) of patients were already HIV+ at PEP initiation.

Of those diagnosed HIV+ whilst still on PEP, 11/16 (68%) opted to continue ART. A decision was made to stop PEP in 5 patients (mean number of days on PEP; 10); this advice was not influenced by CD4 or HIV RNA. 5/11 switched PEP regimes to first line ART. 2/18 had drug resistance: K103N, T215D at diagnosis.

Conclusions: Patients presenting for PEP after sexual exposure are high-risk individuals who may be seroconverting at the time of presentation. It is essential that if a POCT is used at screening, this is accompanied by a 4th generation test as near to initiation as possible, and that dual therapy (as still recommended in some guidelines) must be avoided in this setting.

Acute HIV diagnosis whilst on PEP represents an opportunity for early ART with reduction of viral reservoirs and improvements in CD4 outcome. In the absence of specific data to inform best practice, we recommend continued ART until urgent review by an HIV specialist.

Session S-7 Symposium Room 613

4:00 pm – 6:00 pm

From Pathways to Paradigms: Applications of Systems Biology to HIV/Host Interactions

171 Using Systems Approaches to Study Pathogenesis: Bridging Networks and Mechanisms

Nevan Krogan

University of California San Francisco, San Francisco, CA, US

There is a wide gap between the generation of large-scale biological data sets and more-detailed structural and mechanistic studies. However, recent work that explicitly combine data from systems and structural biological approaches is having a profound effect on our ability to predict how mutations and small molecules affect atomic-level mechanisms, disrupt systems-level networks and ultimately lead to changes in organismal fitness. Our group aims to create a stronger bridge between these areas primarily using three types of data: genetic interactions, protein-protein interactions and post-translational modifications. Protein structural information helps to prioritize and functionally understand these large-scale datasets; conversely global, unbiasedly collected datasets helps inform the more mechanistic studies. Recently, we have been studying the host-pathogen interface

using a series of proteomic and genomic approaches, which has revealed insight into global mechanisms of pathogenesis but has also uncovered important specific insight into the how specific pathogenic proteins re-wire the host during infection. Effort is now ongoing to connect this information to clinical data especially to sequence information from relevant cohorts. Recent progress in these areas will be discussed.

172 Molecular Basis of T-Cell Exhaustion

E. John Wherry

University of Pennsylvania, Philadelphia, PA, US

T cell exhaustion is common during chronic infections in animal models and in humans as well as in cancer and can prevent optimal immunity. Exhausted T cells are defined by the loss of ability to perform effector functions efficiently, low proliferative capacity and poor survival following antigen stimulation. In addition, it has become clear that exhausted T cells co-express multiple inhibitory receptors that negatively regulate their function. Indeed, receptors such as PD-1 have become major targets of clinical immunotherapies in cancer and infectious disease aimed at re-invigorating exhausted T cells. We have used genomic and systems biology approaches to define transcriptional networks of T cell exhaustion revealing key molecular pathways, modules and central "hub" genes involved in this state of T cell dysfunction. Recent work has focused on the role of centrally involved transcription factors, including T-bet and Eomesodermin (Eomes). T-bet and Eomes control a proliferative hierarchy necessary to maintain exhausted T cell populations during chronic infection where these subsets of exhausted T cells exert partial ability to contain, but not control chronic viral replication. Moreover, our studies revealed unique context-specific functions for T-bet and Eomes since these transcription factors are associated with different roles in functional memory T cells. Additional studies are focusing on the role of other transcription factors as well as the molecular and systems biology signatures of reversal of T cell exhaustion. Ultimately, a more precise molecular understanding of T cell exhaustion should lead to novel and more robust clinical interventions to reverse or prevent exhaustion in settings of persisting infections such as HIV.

173 A Systems Biology Approach to Identify Targets and Mechanisms of HIV Latency and HIV Eradication

Rafick P. Sekaly

Case Western Reserve University, Cleveland, OH, US

There is intense interest in developing safe and scalable curative interventions for Berlin patient has paved the way to identify therapeutic interventions that can lead to eradication of HIV. This goal can only be achieved by identifying the cellular localization of the HIV reservoir, the molecular mechanisms that result in the establishment and maintenance of latent infection and host determinants that dictate who might or might not respond to curative interventions. We have used an unbiased system biology approach to identify signal transduction pathways and transcriptional nodes that can predict the size of the HIV reservoir—as estimated by integrated HIV DNA levels—in a large cohort of long-term antiretroviral-treated adults. We show that distinct intracellular pathways associated with cell metabolism, activation and differentiation predict the estimated size of the reservoir. We found that upregulation of TGF-beta was associated with higher reservoir size, and validated the importance of the TGF-beta pathway in vitro using a primary T cell model of HIV latency. Finally we have shown that a specific subgroup of subjects who fail to reconstitute their immune system after ART (immune non-responders) have significantly higher levels of HIV replication competent latent HIV . We show using integrated OMICs approaches that the balance between FOXO3A and IRF-7 is a correlate of immune reconstitution and the size of the reservoir. System biology approaches have proven an essential tool in providing highly relevant clues that could lead to the identification of novel curative interventions. This work was funded by grants from the NIH U19 AI096109, Merck Research Laboratories, and the Fasenmayer Foundation.

174 Translating Anti–HIV-1 Immune Mechanisms Into Clinical Interventions

Sallie R. Permar

Duke University, Durham, NC, US

HIV-1 transmission occurs in a complex *in vivo* setting, with innate and adaptive immunity, host genetics, and virus diversity all contributing to the risk of virus acquisition. As we expand our repertoire of techniques to measure HIV-1-specific immune responses and viral and host factors, we have both sharpened our ability to dissect the protective role of HIV-1-specific immune responses, as well as clouded the picture through measurement of immune responses and host factors with overlapping functions and roles. Thus, novel methods are needed to probe immune mechanisms that underlie the measured immune responses with overlapping, redundant, and correlated functions to make predictions about the unmeasured immune phenomenon that may contribute to interrupting HIV-1 transmission *in vivo*. Maternal antibody is known to protect the infant against acquisition of microbial pathogens, yet the role of maternal antibody in protection against mother to child transmission of HIV-1 remains unclear. In this talk, I will discuss our application of multivariable immune correlate analysis to cohorts of HIV-1-transmitting and non-transmitting women and the insights gained on the role of both the measured immune responses that associated with reduced transmission risk and the underlying immune mechanisms on vertical HIV-1 transmission. Moreover, I will discuss strategies to further probe the hypotheses generated by these immune correlate analyses in both nonhuman primate and human studies. Insights gained from detailed analysis of immune correlates and studies of their underlying mechanisms combined with strategies for hypothesis testing can inform the next generation of immune-based interventions to prevent or treat HIV-1 infection.

Session S-8 Symposium — Room 6D

4:00 pm – 6:00 pm

Scale-Up of Interventions

175 From Equipoise to Efficacy to Millions Reached With Voluntary Medical Male Circumcision for HIV Prevention

Jason B. Reed

US Department of State, Office of the Global AIDS Coordinator, Washington, DC, US

Data from three randomized controlled trials in sub-Saharan Africa demonstrated voluntary medical male circumcision (VMMC) reduces males' risk of HIV acquisition by approximately 60%, making it one of the most effective HIV prevention interventions. VMMC also reduces the risk of several sexually transmitted infections (STI) in males and their female partners, and reduces females' HIV risk as their probabilities of encountering HIV-infected male sexual partners decrease.

In 2011, WHO and UNAIDS set a target of reaching 80% circumcision coverage among males aged 15-49 years in 14 priority countries in east and southern Africa, equivalent to over 20 million VMMCs by the end of 2016. According to mathematical models, this could avert 3.4 million new HIV infections within 15 years and save up to US$16.5 billion in HIV care and treatment costs. Through the end of U.S. fiscal year 2014, PEPFAR had supported more than 6.5 million VMMCs in the priority countries.

Strategic priorities within VMMC scale up have evolved as programs matured. Stakeholders have progressively focused on: community engagement and sensitization; establishing favorable policy environments; instituting safe surgical services and safety monitoring systems; and, balancing supply and demand in continually expanding programs. As experience has grown, global and national stakeholders expanded focus to identify supply- and demand-side efficiencies through implementation research and delivery science.

Population-based survey and study data show disproportionately low health service uptake among men, including poor HIV-related service uptake and outcomes. VMMC is uniquely positioned to initiate positive health system encounters and support HIV case finding among males who may not otherwise test for HIV. As care and treatment programs endeavor to achieve the UNAIDS 90-90-90 goals by 2020, it will be important to maximally leverage the VMMC platform to help ensure requisite male representation within the treatment cascade.

Global health resources, including those for VMMC, are under increasing scrutiny to deliver demonstrable impact. Continued investment in VMMC will require refocusing efforts on intensifying HIV incidence reductions by prioritizing geographic areas and age groups according to HIV risk. Offering VMMC to those most at risk achieves epidemic control with fewer procedures and keeps VMMC on pace to support the UNAIDS goal of ending the global AIDS epidemic by 2030.

176 Scale-Up of HIV Interventions for People Who Inject Drugs: Quality and Coverage

Anna Deryabina

ICAP at Columbia University, Almaty, Kazakhstan

It is estimated that, of the estimated 13 million people who inject drugs (PWID) worldwide, 13% are living with HIV. Eastern Europe, Central Asia, South and South East Asia have the largest injection drug-use driven HIV epidemics. However, recent data show an increasing role of injection and non-injection drug use in HIV transmission in several African countries, including South Africa, Kenya and Tanzania. Criminalization of drug use, restrictive drug policies, aggressive law enforcement practices and lack of availability of harm reduction as well as HIV prevention, care and treatment programs for PWID undermine the ability to respond effectively to the HIV epidemic among PWID. The recommended package for PWID includes nine interventions, four of which (needles and syringe programs, opioid substitution therapy (OST) programs, HIV testing and counseling, and antiretroviral therapy (ART)) are core and have synergistic impact of reducing HIV transmission and enhancing outcomes among PWID with HIV. However, in many countries availability and access to evidence-based interventions remains limited. In many of the most affected countries programs like OST remain small-scale pilots, while coverage of eligible PWID with HIV prevention interventions and ART remains by far insufficient to effectively control the epidemic in this population. Rapid scale-up of effective interventions to reduce drug consumption and unsafe injecting practices is needed to prevent further spread of HIV among PWID, their intimate partners and the society in general. Scale up is about quality and comprehensiveness of services delivered. Effective and comprehensive programs to prevent HIV transmission from PWID to others include implementation of accessible HIV testing and counseling services, including rapid HIV testing, prompt initiation of ART, especially among those living in discordant couples, and scale up of OST programs to reduce HIV burden among PWID; and for PWID living with HIV to enhance their engagement and adherence to HIV treatment. Scale up is also about access and engaging PWID in the design and implementation of programs and prioritizing health of individuals and health of the community at all level of decision-making and implementation. Programs need to ensure that HIV interventions are low-thresh hold, utilize innovative and flexible models to meet the needs of PWID.

177 HIV Testing and Counseling: Emerging Issues, New Directions

Rachel C. Baggaley

World Health Organization, Geneva, Switzerland

With 14 million people on ART the push is now to reach the remaining estimated 20 million who are living with HIV, many of whom are undiagnosed. The UNAIDS 90-90-90 target aims for 90% of all people living with HIV to know their status by 2020. 33% more people were tested in 2013 compared with 2009, however it is estimated that over half (54%) of people with HIV are still unaware of their status.

Routine offer of provider initiated testing and counselling (PITC), recommended by WHO since 2007, is widely accepted in ANC and TB services, including in countries with low HIV prevalence, but has not been as well adopted in other clinical settings, even where HIV prevalence is high. This has led to disparities in testing: men, adolescents and people from key populations are less likely to be reached by HTC through clinical services, resulting in lower testing coverage and later access to HIV care. Reliance on testing through clinical services also partly explains the persistent late presentation of people living with HIV to care.

In 2013 WHO recommended that countries expand testing to include a range of community based approaches to overcome PITC limitations. Approaches to reduce structural and legal barriers to community HTC include legitimising lay testing and the use of rapid tests outside clinical settings; exploring effective HIV self-testing models; and reviewing age of consent to support adolescent testing. Recent approaches to increase the proportion of people diagnosed include community-based testing accompanied by geographic prioritization and targeting populations at greatest risk and partner and family testing. Recent evidence also points to several interventions to rationalize and simplify re-testing for those at ongoing risk and better link people to HIV prevention and care.

In response to emerging evidence of significant problems with testing quality, with reports of up to 7% false positive diagnoses of HIV in people being offered ART, WHO re-emphasised its recommendation to all countries to re-test all people before initiating ART. The causes of these misclassifications and measures to reduce them are being explored to avoid the social and public health consequences of misdiagnosis. HTC approaches have evolved and a range of complementary strategies are now available to reach greater numbers of people. HTC is the first step in both accessing care and preventing further transmission. It will be key to achieving global targets.

178 Ten Years of Strengthening Laboratory Services and Systems: Then, Now, and the Future

John Nkengasong

US Centers for Disease Control and Prevention, Atlanta, GA, US

The last 10 years have been transformational for laboratory medicine in Africa thanks to increase in global health funding, especially from the world bank, PEPFAR, the Global fund—etc. Laboratory networks have been established, systems developed, and human competent work force developed —etc. In fact a recent Institute of Medicine (IOM) report has described laboratory health system strengthening as a "signature achievement" for PEPFAR and also concluded that the progress in strengthening laboratory medicine has also impacted other health systems.

The talk will expand on some of these aspects and address key challenges that remain. It will also demonstrate how laboratory systems build for HIV are being leveraged on to support other program areas such as global health security and TB.

HCV: New Frontiers and Controversies

179 Pathogenesis of Acute HCV Infection

Ashwin Balagopal

Johns Hopkins University School of Medicine, Baltimore, MD, US

Hepatitis C virus (HCV) infects 170 million people worldwide; most persons who are acutely infected will develop chronic infection, while 25% of people will spontaneously clear the virus. Because of common routes of transmission, HIV-1/HCV co-infection is highly prevalent. In HIV-1/HCV co-infection, the likelihood of spontaneous clearance is worsened. While we do not fully understand the mechanisms underlying spontaneous clearance versus viral persistence, recent progress has uncovered a number of contributing factors: persons at highest risk for developing chronic HCV infection are older, male, and of African descent. The racial predisposition is partly explained by recently discovered genetic markers in the Interferon Lambda (*IFNL*) gene locus, which are among the most strongly predictive genetic markers of susceptibility to an infectious disease. There has been some progress in identifying the cause underlying the *IFNL* cluster of genes, although questions still remain. Notable defects have also been found in cytotoxic T cells and NK cells that may contribute to HCV persistence. When studying hepatitis C under the microscope, we have seen evidence of clustered infection of hepatocytes, strongly suggesting that local processes foster hepatitis C propagation.

Several clinical controversies have emerged in the management of acute HCV infection. Although public health measures have been effective at attenuating the incidence of acute HCV transmission in urban centers, there is evidence that increased rates of injection drug use in non-urban and rural settings has resulted in emerging outbreaks in these settings. There has also been evidence of outbreaks of acute HCV among HIV-1 infected men who have sex with men. With respect to treatment in the era of direct-acting antivirals, there has been discussion about whether universal treatment should be recommended: currently, AASLD/IDSA guidelines continue to support a period of monitoring patients for spontaneous clearance. However, as therapies evolve, it is likely that more patients will be treated during the acute period.

180 HCV Treatment as Prevention: Challenges and Opportunities

Gregory Dore

University of New South Wales, Sydney, Australia

Major recent advances in hepatitis C virus (HCV) therapeutic development, with highly curative well tolerated all oral regimens now available have raised the prospect that treatment could provide considerable prevention impact. Mathematical modelling has demonstrated that rapid scale-up of interferon-free direct acting antiviral (DAA) therapy among people who inject drugs (PWID) to levels of 4-8% treated per annum would lead to near elimination of HCV within 20 in settings with a chronic HCV prevalence of 25-50%.

Concerted efforts in several areas are required to enhance the feasibility of HCV treatment as prevention. HCV therapeutic regimens with pangenotypic activity, single daily dosing and short duration (4-6 weeks) would be optimum. HCV screening rates need to be increased, particularly among PWID and HIV-infected men who have sex with men (MSM). HCV treatment infrastructure needs to be broadened to provide access through community-based clinics, drug and alcohol services, harm reduction facilities, and prisons. Community engagement including peer-based worker involvement in HCV screening, disease assessment and treatment delivery programs needs to be developed. Finally, drug price reform and public health advocacy will be instrumental to enable levels of HCV treatment coverage among marginalised populations that would provide major prevention impacts.

Two major Australian HCV treatment as prevention initiatives will be described. The SToP-C project is evaluating HCV treatment as prevention in the prison system in New South Wales. A surveillance phase will monitor HCV incidence in four prisons (two maximum security, two medium security), followed by rapid scale-up of interferon-free DAA therapy with ongoing monitoring of HCV transmission. The CEASE project is evaluating HCV treatment as prevention within the HIV-infected population, predominantly MSM. Components include characterisation of the HIV/HCV population through an observational database (CEASE-d), surveillance for newly acquired HCV and modelling (CEASE-m), education of HIV prescribers in HCV management (CEASE-e) and scale-up of HCV treatment (CEASE-t).

181 HCV Therapeutics: It's the Virus, Stupid

Mark Sulkowski

Johns Hopkins University School of Medicine, Baltimore, MD, US

In 1986, Hoofnagle and coworkers reported the initial use of recombinant interferon alfa to treat patients with non-A, non-B hepatitis, demonstrating improvement in serum ALT levels in most patients. Over the ensuing decade, hepatitis C virus was identified cause of non-A, non-B hepatitis and molecular techniques were applied to test HCV RNA response during therapy, and it became apparent that the majority of persons treated with interferon alfa did not achieve HCV eradication (Sustained Virologic Response, SVR). Further, the poor safety and tolerability of interferon alfa prohibited treatment of many HCV-infected patients. In 1995, several studies demonstrated that the addition of the guanosine nucleoside analogue ribavirin to interferon led to higher SVR rates despite the lack of HCV RNA reduction with ribavirin monotherapy. In 2003, the first report of a potent direct acting antiviral (DAA), an inhibitor of the HCV NS3/4A protease known as BILN 2061, was published, and, in 2011, two HCV NS3/4A protease inhibitors, telaprevir and boceprevir, entered clinical practice as part of "triple therapy" with interferon/ribavirin, and, while toxicity limited their effectiveness, the DAA era was launched. In 2012, proof of HCV eradication by the interferon-free, combination of a HCV NS3/4A protease inhibitor and a NS5A inhibitor was published. In 2015, multiple, interferon-free, combinations of DAAs targeting HCV nonstructural proteins (e.g.,NS3/4A protease, NS5B polymerase and NS5A) have been approved by regulatory authorities. Remarkably, 12 weeks of treatment with these DAA regimens can deliver high rates of HCV cure (> 95%) with minimal adverse effects in diverse range of patients including those with HIV coinfection and decompensated liver disease. In this era, historical barriers to HCV cure linked to the necessity for interferon alfa have been overcome. In their place, new challenges have emerged including the cure of persons with HCV genotype 3 infection and those with advanced liver disease among whom SVR rates are lower than observed in other patient groups as well as the specter of HCV drug resistance in persons who fail to achieve HCV eradication following treatment. However, the greatest challenge will be the need to rapidly translate these remarkable advances in HCV therapeutics to the large global community of persons chronically infected with hepatitis C to prevent the development of life-threatening complications of HCV disease.

182 HCV Therapeutics: Big Sticks With Big Stickers

Marion G. Peters

University of California San Francisco, San Francisco, CA, US

The new all oral direct acting antiviral agents (DAA) for HCV have permanently changed the treatment landscape for patients with Hepatitis C (HCV). Because of better tolerability, fewer side effects and shorter length of therapy, the majority of HCV patients are now eligible for treatment and most patients who know they have HCV are eager to be treated.

However these drugs are expensive. Health care systems throughout the world are trying to determine how and to whom to provide HCV therapy. While those with severe disease clearly are in greatest need, recent data has revealed benefits in morbidity and mortality even in those without severe fibrosis. In addition, extrahepatic benefits accrue with

successful eradication of HCV. Cost effectiveness studies have shown DAA to be cost effective. The cost and range of prices of DAAs vary dramatically in, and within, the USA, and throughout the world. There is great diversity in how individual countries have tackled the problem of cost and access for their HCV patients.

Additionally, access to drug in resource-limited countries may be affected by access to diagnostics and care. Some countries and providers have included HCV care in already existing HIV settings while others do not know the extent of their HCV epidemic. Cost studies must include the cost of diagnostics and clinical care as well as the cost of DAAs. Generics and pan genotypic DAAs may well reshape access in resource limited countries. As more DAAs enter the market, cost adjustments may be made which will increase access to HCV treatment.

The impact of SVR on all cause mortality appears to show a clinical and cost effective benefit in treating early, beyond the benefit of stopping fibrosis progression and preventing further liver disease manifestations. These benefits will influence who to treat and cost benefit effectiveness analyses in the future.

POSTER ABSTRACTS

TUESDAY, FEBRUARY 24, 2015

Session P-A1 Poster Session **Poster Hall**

Cellular Innate Immunity

183 STAT5 Inhibition Reduces HIV-1 Infection and TLR7/8 Responses in Human Macrophages

Sofia Appelberg[1]; Carla N. Mavian[1]; Julie C. Williams[1]; Philip Lichlyter[1]; John Sleasman[2]; Maureen M. Goodenow[2]

[1]University of Florida, Gainesville, FL, US; [2]Duke University, Durham, NC, US

Background: Persistent production of HIV-1 by cellular reservoirs and chronic immune activation are major challenges in the elimination of infection and in the health of HIV-1 infected individuals. Monocyte derived macrophages (MDM) are significant contributors to continual viral production and chronic inflammation. HIV-1 infection of macrophages activates STAT1, STAT3 and STAT5. Infection also primes MDM rendering the cells hypersensitive to subsequent TLR stimulation. STAT5 has two functional binding sites in the HIV-1 LTR, although the effects of STAT5 activation on HIV-1 infection and immune responses by MDM are unknown. We tested the hypothesis that STAT5 activation supports HIV-1 infection and priming of MDM.

Methods: Human MDM or TZM-bl cells were treated with a STAT5 specific inhibitor or transfected with STAT5a/b siRNA prior to infection with replication competent HIV-1_{AD} or single cycle, luciferase-tagged HIV-1_{JRFL} envelope pseudotyped virus. Inhibition of STAT5 protein was verified by western blots. Infection was monitored by measuring supernatant p24 levels, luciferase enzyme activity, non-integrated *gag* and integrated HIV-1 copies. Cell surface expression of CD4 and CCR5 or intracellular p24 and TLR3, TLR4 or TLR7/8 induced TNF and IL-6 was determined by flow cytometry or ELISA.

Results: Pharmacologic inhibition or siRNA-mediated knockdown of STAT5 significantly reduced HIV-1 infection of MDM compared to control. Suppression of *de novo* or established infection by STAT5 inhibition was independent of changes in CD4 or CCR5 surface expression or number of non-integrated *gag* or integrated HIV-1 copies, but related to a significant reduction in HIV-1 LTR activity. STAT5 inhibition dramatically reduced TNF and IL-6 production mediated specifically through TLR7/8, but not through TLR3 or TLR4, in both infected and uninfected cells.

Conclusions: Our novel findings show a direct and indirect role for STAT5 in modulating HIV-1 infection in MDM. STAT5 directly support transcription of the viral genome, with no effect on host cell expression of CD4 or CCR5 and steps in the viral life cycle from entry through integration. STAT5 is involved in pro-inflammatory cytokine production induced by the TLR7/8 receptors, which sense ssRNA and viral infections, indicating an indirect role in HIV-1 infection. Disruption of TLR7/8 signaling mediated by STAT5 inhibition provides no apparent advantage for the virus. Thus, STAT5 is a key factor for HIV-1 replication and a novel anti-viral drug candidate.

184 Regulation of the Innate Immune Sensing of HIV by the Viral Capsid and the Cytosolic DNA Sensor cGAS

Nicolas Manel

Institut Curie, Paris, France

Background: Dendritic cells (DCs) play an important role in the detection of viral infections through innate sensing pathways and the induction of immune responses. The pathogenic virus HIV-1 escapes cytosolic innate immune sensing by monocyte-derived DCs. Innate sensing of HIV-1 by DCs can be rescued by complementing the virus with the small protein Vpx found in HIV-2, attributing the lack of cytosolic sensing of HIV-1 to to the poor ability of the virus to replicate in MDDCs as a result of the SAMHD1 restriction. In contrast, VSV-G-pseudotyped HIV-2 efficiently infects MDDCs and activates pathways of innate immunity. HIV-2 is much less pathogenic than HIV-1, suggesting that such recognition by DCs may be important for effective anti-HIV immune responses. However, the mechanism of cytosolic HIV sensing by DCs remained to be determined.

Methods: Initial experiments showed that the viral capsid and its interaction with the cellular protein Cyclophilin A plays an important role. To study HIV sensing, we designed mutations in capsid to increase its affinity for Cyclophilin A (HIVac).

Results: Strikingly, HIVac mutated viruses maintained the ability to activate DCs but had lost the ability to infect the DCs. Using such virus, we found that innate sensing requires synthesis of the viral cDNA, but not nuclear entry and genome integration. We also find that the wild-type HIV-1 capsid normally shields the cDNA before genome integration, preventing its detection by innate sensor(s). Finally, we examined cytosolic DNA sensors using RNAi. We find that the cytosolic DNA sensor cGAS (cyclic GMP-AMP synthase) is required for innate recognition of HIV-1 and HIV-2 cDNA by DCs.

Conclusions: Altogether, these results establish that cGAS is an important innate sensor of HIV-1 and HIV-2 and uncover an essential regulation of this sensing mechanism by capsid and Cyclophilin A. We are currently investigating various aspects of these innate immune mechanisms and new findings will be presented.

185 cGAS Induced Type I IFN Responses in Dendritic Cells From HIV Elite Controllers

Enrique Martin-Gayo[1]; Jacqueline Cronin[1]; Zhengyu Ouyang[1]; Taylor Hickman[1]; John Trombetta[2]; Florencia Pereyra[1]; Bruce Walker[1]; Alex Shalek[1]; Mathias Lichterfeld[3]; Xu Yu[1]

[1]Ragon Institute of MIT, MGH and Harvard, Boston, MA, US; [2]MIT Institute for Medical Engineering & Science, Boston, MA, US; [3]Massachusetts General Hospital, Boston, MA, US

Background: Cell-intrinsic HIV-1 immune recognition by IFI16 in CD4 T cells can cause pyroptosis, CD4 T cell loss, and increased immune activation. However, such cell-intrinsic immune responses in alternative cell subsets are thought to contribute to protective immune activity against HIV-1. Indeed, our previous studies indicated an accumulation of viral reverse transcripts and a rapid and sustained cell-intrinsic type I IFN response in primary conventional dendritic cells (cDC) from Elite controllers (EC) upon HIV-1 infection, which was functionally relevant for inducing and supporting effective HIV-1-specific CD8 T cell responses. However, molecular mechanisms accounting for such efficient cell-intrinsic immunity against HIV in cDCs from these patients remain unknown.

Methods: cDCs from EC, untreated chronic progressors (CP), HAART-treated and HIV-1 negative subjects were *ex vivo* infected with HIV-1, followed by assessments of expression changes of putative cytoplasmic DNA sensors. siRNA-mediated gene silencing was used to identify host factors responsible for the induction of cell-intrinsic immune responses. Single-cell RNA-Seq analysis of HIV-1-infected cDC was conducted to indentify gene expression pathways associated with cell-intrinsic HIV-1 immune recognition in cDC.

Results: Induction of IFN-I secretion in cDC depended on recognition of viral reverse transcripts by cGAS, but was largely unaffected by IFI16 or other known antimicrobial DNA sensors. RNAseq profiles obtained from single cDCs from EC infected with HIV-1 revealed the existence of distinct subpopulations of cells, characterized by differential expression of genes related to IFN signaling, immune activation, cytokine signaling and cellular metabolism, consistent with cell-intrinsic immune responses that are associated with improved stimulation of antigen-specific T cell responses.

Conclusions: Cell-intrinsic immune recognition of HIV-1 by cGAS in cDC induces type I IFN responses that initiate complex changes in gene expression profiles leading to functional maturation that can enhance antiviral immunity in elite controllers. These data suggest that cell-intrinsic immune recognition of HIV in CD4 T cells and in cDC can have distinct, and partially opposing functions in HIV-1 disease pathogenesis.

186 Characterization of Interferon-α Subtypes in the LPAC Model

Michael Harper[1]; Kathrin Gibbert[2]; Eric Lee[1]; Kejun Guo[1]; Stephanie Dillon[1]; Martin McCarter[3]; Ulf Dittmer[2]; Cara C. Wilson[1]; Mario Santiago[1]
[1]University of Colorado Anschutz Medical Campus, Denver, CO, US; [2]University of Duisburg-Essen, Essen, Germany; [3]University of Colorado Anschutz Medical Campus, Aurora, CO, US

Background: IFNα can inhibit acute HIV infection but is also associated with pathogenesis. The mechanism for this dual impact of IFNα remains unknown. There are 12 IFNα proteins but only one, IFNα2, has been used clinically. The IFNα subtypes are biologically distinct yet difficult to distinguish due to their high sequence similarity. Here we develop a method based on next-generation sequencing (NGS) to enumerate the relative abundance of different IFNα subtype transcripts. We then determined the relative potency of each IFNα subtype using the Lamina Propria Aggregate Culture model (LPAC), which recreates infection of the gut-associated lymphoid tissue (GALT), a major site of early HIV-1 replication.

Methods: Primer sets for quantitative PCR and Illumina NGS were designed in highly conserved regions that encompass polymorphic sites that can be used for IFNα subtype classification. Since plasmacytoid dendritic cells (pDCs) are the major producers of IFNα and likely migrate to the GALT during acute infection, total IFNα was quantified in RNA from pDCs that were negatively selected from PBMCs and exposed to cell-free R5-tropic HIV-1 (Ba-L) for 6 hours. Moreover, IFNα subtype distribution was determined in LPAC cells ± HIV-1. To determine the potencies of individual IFNα subtypes, each IFNα subtype was added to LPAC cells once at 400pg/mL immediately post-infection with HIV-Bal normalized to 10ng p24/mL. Productive infection was assessed using intracellular p24 flow cytometry and infectious virion release by TZM.bl assay at 4dpi.

Results: Negatively selected pDCs showed an average IFNα induction of >400-fold after 6hrs post HIV-1 exposure (n=5, p=0.0087). NGS analyses showed differential expression of IFNα subtypes in pDCs and LPAC cells co-incubated with HIV-1. In particular, IFNα5, IFNα8, and IFNα1/13 were overrepresented in multiple *ex vivo* conditions. In 2 donors tested so far, IFNα8 was the most potent in restricting productive HIV-1 infection and infectious virion release whereas IFNa16 was the least potent.

Conclusions: We developed a method for quantifying IFNα transcript production and the subtype distribution in primary cells. IFNα subtypes are not equally potent at inhibiting HIV-1. IFNα8 appears to be both highly expressed and the most potent at restricting HIV-1 in an *ex vivo* model of mucosal R5-tropic HIV-1 infection. The novel method presented here will be used to test if IFNα subtype expression profiles correlate with chronic immune activation in chronic HIV infection.

187 HIV Vpu Inhibits NF-kB Activity but Does Not Interfere With Interferon Regulatory Factor 3

Lara Manganaro; Elisa de Castro; Ana Maestre; Adolfo Garcia-Sastre; Ana Fernandez-Sesma; Viviana A. Simon
Icahn School of Medicine at Mount Sinai, New York, NY, US

Background: HIV accessory proteins have been shown to antagonize a number of different host innate restriction mechanisms. In particular, HIV Vpu counteracts the inhibitory effect of Tetherin on particle release and also hampers Tetherin mediated activation of the NF-κB pathway. The role of HIV Vpu in regulating the interferon response to infection by degradation of the Interferon Regulatory Factor 3 (IRF3) has, however, been subject of conflicting reports. We therefore, systematically investigated the expression of IRF3 in primary human CD4+ T cells and macrophages infected with different HIV strains. In addition we also tested the ability of Vpu to interfere with innate immune signaling pathways like NF-κB and IRF3 pathway.

Methods: Primary CD4+ T cells and primary macrophages from several healthy donors were infected with different viruses and the levels of IRF3 were determined by both western blot analysis and intracellular staining. To assess the ability of HIV Vpu to interfere with innate immune pathways, we transfected Vpu into 293T together with different NF-kB or IRF3 reporter plasmids. We used TNF-alpha and transfection of IKKb to selectively activate NF-κB and overexpression of TBK1 to induce IRF3.

Results: Here we report that HIV Vpu variants from different viruses fail to degrade IRF3 in infected primary T lymphocytes and macrophages. We first analyzed by Western Blot the levels of IRF3 in uninfected cells or infected with a HIV wild-type virus or HIV lacking Vpu. We did not observe any changes in IRF3 expression levels. We also used an intracellular staining approach to directly compare the levels of IRF3 at a single cell level in the infected and uninfected cell population. We found that the percentage of IRF3 positive cells in the HIV infected population versus the uninfected was comparable.

In addition, we observed that HIV NL4.3 Vpu had no effect on IRF3 dependent gene expression in reporter assays while it is able to down-modulated NF-κB dependent transcription downstream IKKb activation. Moreover all tested HIV-1 Vpus retained the ability to down-modulated NF-κB activity.

Conclusions: Using different approaches we show that HIV Vpu does not affect the of IRF3 protein expression levels in primary cells during infection. Moreover, we found that Vpu is able to downregulate NFKB but IRF3 dependent transcription. Taken together, these results suggest that HIV Vpu regulates antiviral innate response by only acting on the NF-κB pathway.

188 HIV-1 Exploits CD169 to Evade IFNα-Induced Antiviral State in Myeloid Cells

Hisashi Akiyama[1]; Nora Ramirez[1]; Gregory Gibson[2]; Simon Watkins[2]; Zandrea Ambrose[2]; Rahm Gummuluru[1]
[1]Boston University School of Medicine, Boston, MA, US; [2]University of Pittsburgh School of Medicine, Pittsburgh, PA, US; [3]University of Pittsburgh School of Medicine, Pittsburgh, PA, US

Background: A hallmark of HIV-1 infection in vivo is chronic immune activation concomitant with type I interferon (IFN-I) production. Although IFN-Is induce an antiviral state in many cell types, HIV-1 can replicate even in the presence of IFN-Is in vivo. We have recently identified the IFN-I-inducible protein CD169 as an HIV-1 receptor on myeloid dendritic cells that can mediate robust infection of $CD4^+$ T cells in trans. Since CD169 expression is also induced by IFN-Is on macrophages, we hypothesized that CD169 induced by IFN-I could facilitate productive HIV-1 infection in macrophages in cis and thus offset antiviral effects of IFN-Is.

Methods: To investigate the effect of IFN-Is on HIV-1 replication in myeloid cells, a monocyte cell line, THP-1 or primary monocyte-derived macrophages (MDMs) were treated with IFNα for 48 hours and infected with HIVΔenv-luc reporter virus pseudotyped with HIV-1 Lai (HIV/Lai) or VSV-G (HIV/G) glycoproteins, or replication competent HIV-luc. HIV-1 fusion was measured by the conventional Vpr-BlaM assay. To investigate if $CD169^+$ myeloid cells are productively infected in vivo, lymph nodes (LNs) from pigtailed macaques chronically infected with $RT\text{-}SHIV_{mne027}$ were stained for $p27^{gag}$ and CD169.

Results: As reported previously, HIV/G infection was severely attenuated in IFN-treated-THP-1. Surprisingly, however, replication of HIV/Lai was enhanced in IFN-treated-THP-1 than in untreated THP-1. We found that HIV/Lai fusion was greatly enhanced in IFN-treated-THP-1, while that of HIV/G was severely attenuated. This enhanced fusion and infection depended on CD169 since pretreatment with αCD169 blocking antibody abrogated the enhancement of virus fusion and replication in IFN-treated-THP-1. IFNα treatment of MDMs

also up-regulated CD169 and HIV-1 fusion in treated MDMs was enhanced (2-fold) in a CD169-dependent manner. Interestingly, CD169 enhanced virus replication in MDMs even in the presence of IFNα (>2-fold higher compared to MDMs pretreated with αCD169 blocking antibody). Finally, LNs from SHIV-infected macaques showing signatures of immune activation contained more $CD169^+$ cells than those of uninfected animals and, intriguingly, a large proportion of $p27^{gag+}$ cells were also $CD169^+$.

Conclusions: These studies suggest that HIV-1 has exploited CD169 to attenuate IFN-I-induced antiviral state in myeloid cells.

189 Interferon-Induced Transmembrane Proteins (IFITMs) Antagonize Postintegration Replication of HIV but Are Overcome by Viral Membrane Accessory Proteins

Wingyiu Lee; Ifrah Omar; Richard D. Sloan

Queen Mary University of London, London, United Kingdom

Background: Interferon response triggered by acute HIV infection modulates the expression of genes in both infected and non-infected cells to control viral replication and virus spread. To date, a number of genes have been identified as host antiviral factors that interfere with various steps of the HIV replication cycle. Members of the interferon-induced transmembrane proteins (IFITMs) are induced in human macrophages and $CD4^+$ T cells upon upon exposure to interferons. While IFITMs have been shown to inhibit entry of HIV-1, the effects of IFITMs on other stages of the viral replication cycle are not known. Thus, we investigated the effects of IFITMs expression on the post-entry steps of the HIV replication cycle and how post-translational modification of IFITMs modulates these effects.

Methods: In transfection assays, wild-type or accessory gene-deleted HIV proviral DNA and expression vectors for IFITM1-3 were co-transfected into adherent HEK293T cells. In infection assays, HIV-1 viruses were made from transfected 293T cells and subsequently used to infect SupT1 cells that express human IFITMs upon exposure to doxycycline. Virus released from transfected or infected cells was quantified by p24 ELISA. Expression of viral proteins, IFITMs and other antiviral proteins were evaluated by immunoblotting or intracellular staining and flow cytometry. Quantitative PCR was used to measure the amount of total, multiply-spliced and singly-spliced viral RNA. Immunofluorescence and confocal microscopy were used to visualize IFITMs and viral components in cells.

Results: We show that expression of human IFITMs reduces the quantity of released HIV-1 viral particles produced in cells compared to vector controls. In the absence of the HIV accessory proteins Nef and Vpu, IFITM-mediated antagonism of HIV is more potent (20-30 fold). The reduction of viral output is caused by a decrease in synthesis of viral proteins independent of transcriptional control. While mutation of cysteine residues in IFITM1-2 that perturbs their palmitoylation and concomitant plasma membrane retention led to a reduction in all classes of viral RNA transcripts. This results in highly reduced HIV particle output by 10 to 100-fold compared to the wild-type IFITM1.

Conclusions: Our studies identify a novel role for IFITMs in controlling HIV replication at the post-transcriptional level and show that it is possible to engineer highly active anti-HIV IFITM variants by modulation of their palmitoylation status.

190 HSV-1-Induced Enhancement of HIV-1 Replication Is Dependent on Decrease in IFITM3 Levels

Viviane Andrade[1]; Milene Miranda[2]; Mario Stevenson[1]; Thiago M. Souza[2]

[1]University of Miami, Miami, FL, US; [2]Oswaldo Cruz Foundation, Rio de Janeiro, Brazil

Background: The IFITM3 restriction factor has been described as a protein that impairs HIV-1 replication upon IFN induction. Since herpesvirus infections are extremely common in HIV-1-infected individuals and some HSV-1 proteins inhibit the IFN cascade, we analyzed whether HSV-1 could enhance HIV-1 replication by diminishing the levels of IFITM3.

Methods: Monocyte-derived macrophages were obtained from healthy donors and cells were infected with $HSV\text{-}1_{AR\text{-}29}$ (0.1 or 1 MOI) or co-infected with $HIV\text{-}1_{Ba\text{-}L}$ (10 ng/mL p24 antigen) during 2 or 14 days, respectively. To access HIV-1 quantification, we performed luciferase assay with infected TZM-BI from supernatants of infected-macrophages. The expression of IFITM3 was analyzed by immunoblotting with an anti-rabbit antibody against IFITM3. Knockdown of HSV-1 proteins was performed with siRNA against Us11 and VHS transcripts and further qPCR analysis to confirm knock down.

Results: Upon HIV-1-HSV co-infection, we observed a 3- 7 fold increase in HIV-1 production. At an HSV-1 MOI of 1,we observed a reduction in IFITM3 levels by 48 h post-infection. We analyzed changes in IFITM3 levels during the first 24 h of HSV-1 infection. Changes in IFITM3 occurred primarily at the late stages of HSV-1 infection. Treatment with ACV or IFN-2α prevented reduction of IFITM3, indicating that viral replication and ability to overcome IFN signaling are critical for IFITM3 modulation. To confirm that HSV-1 proteins produced at the late phase of replication are indirectly reducing IFITM3 levels by inhibiting the IFN cascade, Us11 and VHS was silenced. This was sufficient to prevent HSV-1-induced IFITM3 reduction. siRNA-mediated silencing of US11 and VHS also consistently prevented HSV-1-mediated enhancement of HIV-1 production.

Conclusions: Increased HIV-1 replication observed during HIV-1/HSV-1 co-infection is due to the production of Us11 and VHS by HSV-1. Upon inhibiting the IFN cascade, IFTM3 levels are reduced which contributes to an increased replication of HIV-1 in co-infected macrophages. Since co-infections are common in HIV-1 infected-individuals, our findings provide additional for exacerbation of HIV-1 replication in HSV-1/HIV-1 co-infected individuals.

191 Characterization of the Activity of an Innate Immunity Protein, the Apolipoprotein L6

Nitisha Pyndiah[1]; Angela Ciuffi[1]; Amalio Telenti[2]

[1]Institute of Microbiology, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland; [2]J Craig Venter Institute, San Diego, CA, US

Background: Host restriction factors are proteins hampering virus replication, and share common features including positive selection, viral counteraction, interferon-inducible expression and differential expression among HIV+ patients. APOL6 was identified in a screen aiming at identifying novel HIV-1 candidate host restriction factors. Another member of the APOL family, APOL1, has been previously described for its protective role against the parasite *Trypanosoma brucei* and more recently as a new HIV restriction factor (Taylor *et al.,* 2013). The aim of the study was to characterize the activity of APOL6.

Methods: We evaluated the ability of APOL6 primate orthologues, chimeras and mutants to inhibit the GFP expression from an HIV-1 based genomic vector in co-transfection experiments. We also assessed the impact of APOL6 on transduction of reporter viruses. Analysis was carried out using flow cytometry

Results: APOL6-mediated restriction was validated in a co-transfection assay with an HIV-1 LTR-EF1-GFP, showing up to 10-fold reduced GFP expression in APOL6-expressing cells compared to control cells. Species-specific restriction of APOL6 primate orthologs co-transfected with HIV-1 LTR-EF1-GFP revealed a higher GFP inhibition mediated by hominids and new world monkey APOL6 compared to old world monkeys APOL6. A similar APOL6-mediated inhibition was observed when APOL6 was co-transfected with alternate GFP expression vectors. In contrast, APOL6 was not able to restrict HIV-based vector transduction nor adenovirus or LCMV. Furthermore, APOL1 and APOL3 constructs were also tested in co-transfection and transduction experiments and followed the same tendency as APOL6. Through co-transfection analyses using human and rhesus APOL6, respectively displaying high and low inhibition ability, we identified a specific APOL6 domain and residue mediating APOL6 effects.

Conclusions: All together, these data suggest that APOL6-mediated activity is not virus-specific, but rather displayed a broad action against various promoter constructs. This points out to a specific APOL6 mechanism, potentially acting at the level of nucleic acid (DNA or RNA) sensing and/or degradation. APOL6 domain and residue responsible for the activity was identified. The mechanism used by APOL6 is very likely to be shared by other members of the family. We are currently identifying APOL6 cellular interactants by Mass spectrometry to elucidate the mechanism of APOL6-mediated restriction.

192 HIV and SIV Inhibition by RNA-Associated Early Stage Antiviral Factor (REAF)

Aine McKnight
Queen Mary University of London, London, United Kingdom

Background: The interaction of viruses with their human host is a constant war. The discovery of novel anti-viral restriction factors illuminates unknown aspects of innate sensing and immunity.

Methods: An siRNA screen of ~20,000 human genes was used to uncover those involved in inhibition of HIV replication. We identified RNA-associated Early-stage Anti-viral Factor (REAF) as an inhibitor of HIV replication

Results: 114 genes were identified to be potentially involved in intrinsic resistance. Focusing on the most potent factors led us to REAF. REAF (previously RPRD2) was annotated in the human genome but with no known function. We observed more than 50 fold rescue of HIV-1 infection following knockdown of REAF by specific siRNA. Quantitative PCR was used to measure the effect of REAF knockdown on two steps in the replication cycle – production of reverse transcripts and integration of viral cDNA. Both steps were strongly enhanced. Conversely, when REAF is over expressed in target cells fewer reverse transcripts are produced. Human REAF can also inhibit HIV-2 and simian immunodeficiency virus (SIV) infection. REAF interacts (either directly or indirectly) with HIV RNA or RNA:DNA intermediates during reverse transcription. Also, during the process of reverse transcription REAF protein is degraded, within one hour of infection, in a proteosomal dependent manner.

Furthermore, REAF can inhibit HIV replication via different routes of entry into cells. Its potency is, however, highly dependent on the pathway of entry used and we show it is the lentiviral restriction factor 2 (Lv-2) [1,2].

Conclusions: We propose that REAF is part of an anti-viral surveillance system destroying incoming retroviruses. This novel mechanism could apply to invasion of cells by any intracellular pathogen.

1 Marchant, D., Neil, S. J., Aubin, K., Schmitz, C. & McKnight, A. An envelope-determined, pH-independent endocytic route of viral entry determines the susceptibility of human immunodeficiency virus type 1 (HIV-1) and HIV-2 to Lv2 restriction. *J Virol* **79**, 9410-9418, (2005).

193 Translational Control of APOBEC3G/F Restriction Factors by the HIV-1 Vif Protein

Camille Libre[1]; Santiago X. Guerrero[2]; Julien Batisse[1]; Roland Marquet[1]; Jean-Christophe Paillart[1]
[1]IBMC CNRS, Strasbourg, France; [2]Centre for Genomic Regulation, Barcelona, Spain

Background: The human immunodeficiency virus type 1 (HIV-1) requires the concerted contribution of many cellular factors to achieve efficient replication. Similarly, mammalian cells express a set of proteins called restriction factors to suppress viral replication. Among these factors, the family of APOBEC3 (Apolipoprotein B mRNA editing enzyme catalytic polypeptide-like 3 or A3) proteins and in particular A3G and A3F are the most efficient against HIV-1. They belong to a large family of cytidine deaminases that catalyze the deamination of cytidines to uridines in single stranded DNA substrate during HIV-1 retrotranscription and is lethal for the virus. The antiviral activity of A3G/F is counteracted by HIV-1 Vif (Viral infectivity factor) protein. Vif significantly reduces their expression in cell and their incorporation into viral particles by 1) recruiting an E3 ubiquitin ligase complex to induce their degradation by the proteasome, and 2) regulating their translation. Up to now, the mechanisms by which Vif regulates the translation of A3G/F are not known.

Methods: To address the role of Vif in the regulation of A3G/F translation, we tested the importance of the unstranslated regions (UTRs) of A3G/F mRNA in the translational inhibition. HEK 293T cells were transfected with wild-type and mutated constructions of A3G and A3F mRNAs (ΔUTRs, Δ5'UTR, Δ3'UTR and ΔSL) in presence or absence of Vif. These experiments were also performed with a proteasome inhibitor (ALLN) in order to distinguish the proteasomal degradation pathway from the translational inhibition.

Results: Although the translation of wild-type A3G/F mRNA is significantly reduced by Vif, we showed that the suppression of their 5'UTRs does not allow these mRNAs to be regulated by Vif anymore, suggesting that the 5'UTR is important for the translation repression. Next, we showed that the two distal stem-loops in the 5'UTR of A3G mRNA are crucial for the translational inhibition. Finally, we observed a strong correlation between the level of A3G/F protein translation in cell, their incorporation into viral particles, and the infectivity of released virions.

Conclusions: Experiments are in progress to identify with precision the mechanisms of A3G/F translational regulation and determine Vif domains involved in this process. Regulating the translation of A3G/F could thus be considered as a new target to restore a functional expression of A3G and viral restriction.

194 Evidence for Lentivirus-Driven Evolution of APOBEC3C

Cristina Wittkopp; Michael Emerman
Fred Hutchinson Cancer Research Center, Seattle, WA, US

Background: The Human APOBEC3 (A3) locus is a family of seven antiviral proteins on chromosome 22. Unlike A3D, A3F, A3G, and A3H, human A3C has little to no activity against HIV-1. However, we have previously found that for A3D and A3H, the homolog from other primates more potently blocks lentiviruses than the human version of these genes. Therefore, we hypothesized that A3C may potently restrict lentiviruses in non-human primates. To test this, we cloned A3Cs from several species and assayed for lentivirus restriction, and also performed evolutionary analyses to look for evidence of a virus-host arms race involving A3C.

Methods: We obtained A3C sequences from 12 primate species, and used the PAML software suite to perfom evolutionary analyses . Five of the A3C genes were cloned into expression vectors and their antiviral activity and sensitivity to Vif were functionally characterized. Antiviral activity was assessed by infectivity assays performed with HIV-1 and SIVagm in the absence of the viral antagonist, Vif. Sensitivity to Vif antagonism was assessed using infectivity assays with HIV-1 proviruses encoding Vifs from diverse lentiviruses. Cells were co-transfected with a provirus and each A3C or a vector control, and virions were harvested and used for infection. Virion and A3C protein expression were analyzed by Elisa and Western blot.

Results: A3Cs were functionally assayed for antiviral activity, and we found that in striking contrast to human A3C, several non-human primate A3Cs potently block HIV-1 and SIVagm (Vif deleted). In support of A3C being an active restriction factor, we found that A3C is evolving under positive selection. Futhermore, we identified rapidly evolving residues within A3:Vif binding domains, suggesting that activity against lentiviruses may drive the evolution of primate A3Cs. Preliminary evidence indicates that primate A3Cs have differential sensitivity to Vif antagonism.

Conclusions: Our functional and evolutionary data suggest that A3C is in genetic conflict with lentiviruses. The potent anti-lentiviral activity of several primate A3Cs, as well as the rapid evolution of residues important for Vif binding, indicate that A3C may play an important role in protecting primates from lentiviruses, but that human A3C has lost this activity. Thus, humans have lost the activity of an APOBEC3 antiviral gene that is present in other primates. We speculate that this lack of activity could impact our susceptibility to cross-species viral transmissions.

195 Reevaluation of the Role of the Small Host Cell GTPase Rab6 in the HIV-1 Replication Cycle

Isaac Zentner; Simon Cocklin

Drexel University College of Medicine, Philadelphia, PA, US

Background: The HIV-1 genome consists of only 9 genes and thus, depends highly on host cellular factors to replicate. Recent studies, through genome-wide siRNA screens, have identified many possible "HIV-1 dependency factors" HDFs. However, there lies a large inconsistency between these analyses and the majority of potential hits have not been verified in primary human target cells. Therefore, the goal of this proposal is to validate a recently identified possible HIV-1 Env-mediated host factor, Rab6A GTPase.

Methods: We utilized siRNA mediated knockdown in multiple cell lines and primary human monocyte-derived macrophages (MDMs) coupled with a HIV-1 single-round infection assay to define the mechanism by which this protein facilitates HIV-1 infection. Additionally, because Rab6A is ubiquitously expressed in two closely related isoforms, Rab6A and Rab6A', that have similar but distinct roles in the cell, both isoforms were investigated. Given that Rab6A is always cycling between active and non-active states, we examined the activity state needed for HIV-1 infection through dominant and constitutively active mutants of Rab6A, as well as knocking down the Rab6A-specific guanine nucleotide exchange factor (GEF), Ric1/Rgp1.

Results: siRNA knockdown of both isoforms of Rab6 in the U87 cell line confirmed its role in the viral replication cycle. Moreover, down regulation of both Rab6 isoforms in 293T cells used to generate virus demonstrated no effect on the overall production or infectivity of viruses, demonstrating that the protein facilitates processes only in the early stage of the replication. Contrary to previous reports, no dependency of the effect of knock down of Rab6 on the HIV-1 envelope was observed. Specific knock down of the individual isoforms, Rab6A and Rab6A', demonstrated that both were utilized by the virus but HIV-1 had a greater dependency upon Rab6A. Similar results were obtained with knockdown studies using primary human monocyte-derived macrophages. Diminishing Ric1/Rgp1 decreased infectivity revealing this Rab6A-specific GEF as an additional host factor for HIV-1.

Conclusions: Taken as a whole, these results demonstrate that Rab6 is co-opted by HIV-1 to facilitate a post entry step in the infection process and this is dependent on Ric1/Rgp1 activity. Further investigations may reveal a novel therapeutic pathway to combat HIV-1/AIDS, as well as help dissect the fundamental biological role of Rab6A(A/A') in primary human macrophages.

Nucleus Entry, Integration, and Export

196 The Mutated Form of Transportin 3 From Patients With Limb-Girdle Muscular Dystrophy 1F Hijacks Wild-Type Transportin 3 and Interferes With CPSF6 Subcellular Localization, Impairing HIV-1 Nuclear Entry

Sara Rodriguez-Mora[1]; Mayte Coiras[1]; Mercedes Bermejo[1]; Elena Mateos[1]; Ramon Marti[2]; Juan Jesus Vilchez[3]; Antonio Luis Andreu[2]; Jose Alcami[1]
On behalf of the AIDS Immunopathogenesis Unit

[1]*Instituto de Salud Carlos III, Madrid, Spain;* [2]*Vall d'Hebron Institut de Recerca, Barcelona, Spain;* [3]*Hospital Universitari i Politecnic La Fe, Valencia, Spain*

Background: Cells from patients with LGMD1F (limb-girdle muscular dystrophy 1F) show a point heterozygous mutation in *transportin 3* (*TNPO3*) gene. These cells expressed both TNPO3-wt and a mutated form with additional 15aa in the C terminus (TNPO3-mut). The interaction between TNPO3 and CPSF6 has been involved in HIV-1 decapsidation and transport of viral DNA to the nucleus, as well as in gene splicing. Our group described previously at HIV-1 pre-integration level was impaired in CD4+ T cells from LGMD1F patients. Now we have immortalized B lymphocytes from LGMD1F patients with the Epstein-Barr virus in order to characterize the mechanism of action of TNPO3-mut to thwart HIV-1 replication.

Methods: The interaction between TNPO3-wt and TNPO3-mut was analyzed in Jurkat E6-1 cells by co-transfection of tagged proteins along with pNL4-3_Renilla infectious clone. The level of expression of CPSF6 in LGMD1F cells and the role of TNPO3-mut in the viral splicing was analysed in B cells immortalized with Epstein-Barr virus from four patients with LGMD1F and two healthy relative controls. B cells were infected with a pseudotyped VSV-DEnv NL4-3_LUC virus.

Results: 1) Co-transfection of pNL4-3_Renilla in the presence of increasing concentrations of tagged TNPO3-mut proved that this form was interfering with HIV-1 replication in Jurkat E6-1 cells, likely due to the hijacking of TNPO3-wt, as was observed by immunoprecipitation. 2) Analysis by immunoblotting and immunofluorescence showed that LGMD1F cells had higher levels of the splicing proteins CPSF6 and SC35 in the nucleus, although the viral splicing was not affected.

Conclusions: HIV-1 replication was thwarted in LGMD1F cells due to the hijack of TNPO3-wt by TNPO3-mut, avoiding the translocation of HIV-1 DNA to the nucleus. As the entry of CPSF6 in the nucleus depends on TNPO3, the presence of TNPO3-mut was somehow inducing the accumulation of high levels of this splicing protein in the nucleus of LGMD1F cells, although the viral splicing was not affected in the immortalized LGMD1F B cells. More experiments would be necessary to determine whether TNPO3-mut is interfering with viral decapsidation through the inhibition of CPSF6 activity.

197 Longitudinal Epigenome-Wide Association Study of Pre- and Post-HIV–Infected Subjects

Sophie Limou[1]; George W. Nelson[1]; Elizabeth Binns-Roemer[1]; Jia Li[1]; Fathi Elloumi[1]; James J. Goedert[3]; Cheryl A. Winkler[1]

[1]*Frederick National Laboratory Operated by Leidos Biomedical Research, Inc, for the National Cancer Institute, Frederick, MD, US;* [2]*Frederick National Laboratory Operated by Leidos Biomedical Research, Inc, for the National Cancer Institute, Frederick, MD, US;* [3]*National Cancer Institute (NCI), Bethesda, MD, US*

Background: For nearly 25 years, extensive genetic and genomic association studies have revealed essential host factors for HIV control and disease progression, which notably led to the development of a new class of antiretroviral inhibitors (*CCR5-△32* association and CCR5 antagonists). Overall, the identified associations account for ~20% of the phenotypic variance suggesting that other factors are yet to be discovered. Epigenetic mechanisms are key regulators of gene expression that are not coded by DNA primary sequence and can impact complex diseases. Here, we evaluated for the first time whether HIV-1 infection modifies the host epigenome DNA methylation patterns.

Methods: We recruited 19 untreated HIV-infected individuals from the DC Gay cohort with longitudinal follow-up and PBMC samples available from pre-infection, early post-infection (<12 months), post-infection during clinical latency and post-infection at or near the inflection point. Following DNA and RNA extraction from the 80 PBMC samples, DNA was bisulfite-converted and genotyped with the Illumina Infinium HumanMethylation450 arrays, covering over 485,000 methylation sites across the genome. After normalizing the data, we compared the DNA methylation profiles of pre-infection *vs.* post-infection samples adjusting for batch effect, age, stage of infection and cell composition.

Results: Our preliminary analysis revealed that host genome DNA methylation profile is impacted by HIV-1 infection and highlighted several significantly differentially methylated sites ($P<10^{-7}$). Most genes where these differentially methylated sites are located have an immune-related function or were previously shown to interact with HIV-1 proteins (*MX1*, *TNFAIP8*, *PARP9*, and *IFI44L* genes in the top 5 hits).

Conclusions: We established a unique collection of samples representing pre-infection and post-infection timepoints, which allows for detection of DNA methylation changes within an individual and between individuals following HIV infection and during the HIV-1 infection course. This first epigenome-wide association study conducted in HIV-infected subjects has identified targets of epigenetic modifications by HIV. Our report indicates that the exploration of host epigenetic mechanisms opens a new promising avenue for discovery of critical host factors interacting with the virus that might be leveraged for translation to drug or vaccine development.

198 IN Variants Retarget HIV-1 Integration and Are Associated With Disease Progression

Frauke Christ[1]; Jonas Demeulemeester[1]; Zeger Debyser[1]; Rik Gijsbers[1]; Jan De Rijck[1]; Thumbi Ndung'u[2]; Paradise Madlala[1]
[1]*KU Leuven, Leuven, Belgium;* [2]*University of KwaZulu-Natal, Durban, South Africa*

Background: Distinct integration patterns of different retroviruses, including HIV-1, have puzzled virologists for over 20 years. A tetramer of the viral integrase (IN) assembles on the two viral cDNA ends, docks onto the target DNA (tDNA) to form the target capture complex (TCC) and catalyzes viral genome insertion into the host chromatin.

Methods: We combined structural information on the Prototype Foamy Virus TCC with conservation in retroviral IN protein alignments to determine aa-tDNA base contacts. We generated HIV-1 variants based on the observed variability at these positions, assessed replication capacities and performed integration site sequencing to reveal their integration preferences. Finally, we examined their effect on disease progression in a chronic HIV-1 subtype C infection cohort.

Results: We identified retroviral IN amino acids affecting molecular recognition in the TCC and resulting in distinct local tDNA nucleotide biases. These residues also determine the propensity of the virus to integrate into flexible tDNA sequences. Remarkably, natural polymorphisms IN_{S119G} and IN_{R231G} retarget viral integration away from gene dense regions. Precisely these variants were associated with rapid disease progression in a chronic HIV-1 subtype C infection cohort.

Conclusions: Our findings reveal how polymorphisms at positions corresponding to HIV IN_{119} and IN_{231} affect local as well as global integration site targeting. Intriguingly, these findings link integration site selection to virulence and viral evolution but also to the host immune response and antiretroviral therapy, since HIV-1 IN_{119} is under selection by HLA alleles and integrase inhibitors.

199 HIV-1 Integration Sites in Macrophages and CD4$^+$ T Cells Are Distinct

Yik Lim Kok; Valentina Vongrad; Mohaned Shilaih; Herbert Kuster; Roger Kouyos; Huldrych F. Günthard; Karin J. Metzner
University Hospital Zurich, Zurich, Switzerland

Background: The host genetic surroundings of integrated HIV-1 provirus have great impact on the activity of the HIV-1 LTR . Thus, HIV-1 integration site (IS) studies will contribute to the understanding of how to reactivate latent HIV-1 provirus, a currently pursued approach to eradicate the latent reservoir. Analysis of *in vivo* HIV-1 IS in macrophages is not feasible as it is too invasive to obtain them from HIV-1$^+$ patients. Moreover, IS analysis in monocyte-derived macrophages (MDMs) has only been done *in vitro* and was never compared to CD4$^+$ T cells within the same experimental settings. In this study, we compared and characterized HIV-1 IS in treated HIV-1$^+$ patients' MDMs and activated CD4$^+$ T cells infected *ex vivo* with the patients' autologous primary HIV-1 isolates.

Methods: 7 patients from the Zurich Primary HIV Infection study were selected based on the following inclusion criteria: (i) Successful viral suppression for ≥2 years and (ii) Efficient replication of autologous primary HIV-1 isolates in donors' MDMs. Patients' autologous HIV-1 and the clonal $HIV\text{-}1_{JR\text{-}FL}$ strain were used. HIV-1 IS were amplified with optimized non-restrictive linear amplification–mediated PCR, and sequenced using next generation sequencing technology. Sequencing reads were subjected to high quality trimming and mapped to the human genome. Gene clustering was done using the online bioinformatics tool DAVID. Fischer's exact test was used for statistical analysis.

Results: A total of 1160 unique HIV-1 IS were analysed. As expected, HIV-1 favours integration into introns of genes. However, autologous HIV-1 was less likely to integrate into introns of genes in MDMs compared to CD4$^+$ T cells ($p<0.01$). Significant difference was not observed between autologous HIV-1 and $HIV\text{-}1_{JR\text{-}FL}$ in MDMs for all genetic features examined. Consistently, analysis with DAVID showed that 37.5% versus 15.8% of enriched gene clusters (DAVID enrichment score≥1.3) in MDMs infected with $HIV\text{-}1_{JR\text{-}FL}$ and CD4$^+$ T cells infected with autologous HIV-1, respectively, overlap with those in MDMs infected with autologous HIV-1. Additionally, we have identified 12 genes in which at least 3 different HIV-1 IS are found between cell types and/or HIV-1 stains. 5 of these genes form an enriched cluster associated with catabolic processes and 3 have been found previously in clonally expanded CD4$^+$ T cells *in vivo*.

Conclusions: HIV-1 IS patterns between MDMs and CD4$^+$ T cells are distinct. Nonetheless, MDMs and CD4$^+$ T cells have common hotspots for HIV-1 integration.

200 A Screening for DNA Repair Enzymes That Affect HIV-1 Infection

Noriyoshi Yoshinaga[1]; Yusuke Matsui[1]; Keisuke Shindo[1]; shunichi Takeda[1]; Akifumi Takaori-Kondo[1]
[1]*Kyoto University, Kyoto-shi, Japan;* [2]*Kyoto University, Kyoto-shi, Japan*

Background: DNA repair enzymes might affect HIV-1 infection, as DNA intermediates of the virus play critical roles in the viral life cycle. Although several such molecules have been reported, interactions between HIV-1 and host DNA repair molecules have not been fully elucidated.

Methods: To screen for DNA repair enzymes that affect HIV-1 infectivity, a set of 33 DNA-repair-deficient DT40 cell lines with a single DNA repair gene deletion was tested for infectivity of VSV-G pseudo-typed NL4-3 with a luciferase reporter. To elucidate which steps in the viral life cycle candidate molecules function, late reverse transcription products, 2-LTR circle DNA, and integrated provirus were measured by quantitative PCR. To ask whether human RAD18 suppresses HIV-1 infection in human cells, knockdown of RAD18 by siRNA was applied to Jurkat cells and the virus infectivity was tested. To identify responsible domain of RAD18, over-expression of RAD18 wild-type, C28F, D221A or L274P was applied to 293T cells, and the virus infectivity was tested.

Results: HIV-1 infectivity in 8 of 33 DT40 cells was less than 50% of that in wild-type cells, suggesting the genes deficient in these cells might be required for efficient HIV-1 infection. On the other hand, the infectivity in Rad18 -/- cells was about 3-fold higher than that in wild type cells, suggesting Rad18 might inhibit HIV-1 infection. Quantitative PCR analyses showed that 4 of 8 DT40 cells with less infectivity accumulated 2-3 fold more 2-LTR circles and less than 50% integrated provirus, suggesting these genes might be required for efficient integration. In addition, Rad18 -/- cells accumulated about 5-fold more viral late RT product at 4h post-infection, suggesting Rad18 might inhibit reverse transcription. Jurkat cells that were transfected with siRNA for human RAD18 showed about 1.5-fold increase in HIV-1 infectivity when compared to cells transfected with a non-silencing control siRNA. Over-expression of RAD18 wild-typed, C28F RING domain mutant or C207F zinc-finger domain mutant in 293T cells inhibited HIV-1 infection, but that of L274P SAP domain mutant of RAD18 did not.

Conclusions: We have identified several candidate DNA repair genes that might support HIV-1 infection. We confirmed that RAD18 suppresses HIV-1 infection, and found that substitution of a DNA-binding residue lost this suppression. Our data support a model in which RAD18 inhibit reverse transcription by directly binding to viral DNA intermediates.

201 The Activity of HIV-1 Rev/RRE Varies Greatly Between Isolates

Patrick E. Jackson[1]; Denis Tebit[1]; David Rekosh[1]; Marie-Louise Hammarskjold[1]

[1]University of Virginia, Charlottesville, VA, US; [2]University of Virginia, Charlottesville, VA, US

Background: HIV replication is a highly regulated process, and the binding of the viral Rev protein to the Rev Response Element (RRE) is essential for the nucleocytoplasmic export of mRNAs that retain introns and thus for packaging of genomic RNA. Previous studies have shown that there is variation in Rev and RRE sequence both within and between patients. We previously assessed the activity of the Rev-RRE system in viruses isolated from patients. Variation of Rev/RRE function was observed between patients and within a patient as the infection progressed. In the present study, we sought to examine whether Rev/RRE functional variation could help to explain changes in the relative prevalence of HIV subtypes in populations.

Methods: A functional assay was developed, which utilizes an HIV vector system that packages HIV vector RNA into particles in a Rev-dependent fashion. The virus particles formed in this system transduce hygromycin resistance to target cells, allowing Rev/RRE activity to be read-out by counting the number of resistant colonies. Rev and RRE sequences can be tested in this system to measure the function of naturally occurring or artificial Rev-RRE pairs. Eight sequences were selected from the Los Alamos database representing two subtype A, four AG, and two G examples. Four subtype B patient isolates were also included.

Results: There was a 24-fold difference in functional activity between the most and least active naturally occurring Rev/RRE combinations (cognate pairs). There was no clustering within withsubtypes. When selected Rev and RRE sequences were tested with NL4-3 RRE and Rev, the absolute activity could not be predicted from the activity of the cognate pair. In a linear regression analysis, there was low correlation of RRE activity (R^2=0.32) but high correlation of Rev activity (R^2=0.95) with the functional activity of the original cognate pair.

Conclusions: Rev/RRE functional activity varied dramatically between naturally occurring cognate pairs. This functional variation appeared to be primarily driven by differences in Rev. The clinical significance of this finding is still unclear, but our results demonstrate that there are clear differences in the Rev activity of circulating viruses. This may play a role in viral fitness and replication dynamics and be reflective of immune pressure. Identification of the most efficient Rev/RRE combination would also likely be of use in optimizing lentiviral vector systems for gene therapy.

Session P-A3 Poster Session — Poster Hall

2:30 pm – 4:00 pm

SAMHD1

202 A Surprising New Function of SAMHD1 as a Pro-Pathogenic Factor in HIV Infection

Gilad Doitsh; Nicole Galloway; Xin Geng; Isa Monus Arias; Zhiyuan Yang; Warner C. Greene

The J. David Gladstone Institute, University of California San Francisco, San Francisco, CA, US

Background: Depletion of CD4 T cells and development of chronic inflammation are signature processes in HIV pathogenesis that propel disease progression. Due to endogenous SAMHD1 restriction activity in quiescent lymphoid CD4 T cells, the viral chain elongation phase of reverse transcription is attenuated, giving rise to incomplete cytosolic DNA transcripts. CD4 T-cell death is triggered after sensing of these cytosolic DNA intermediates by interferon gamma Inducible protein 16 (**IFI16**). Death occurs following caspase-1 activation in inflammasomes and the induction of **pyroptosis**, a highly inflammatory form of programmed cell death. These findings mechanistically connect CD4 T-cell death and chronic inflammation––the two signature pathogenic processes of active HIV infection.

Methods: Human lymphoid aggregated cultures (HLACs) prepared using tonsil and spleen, and lymph node biopsies from consenting HIV-infected volunteers were used.

Results: We now show that SAMHD1 restriction activity influences how CD4 T cells die. Degradation of SAMHD1 by Vpx encoded by HIV-2 thwarts abortive infection in resting, non-permissive lymphoid CD4 T cells redirecting the cell death pathway away from caspase-1-mediated pyroptotic pathway (inflammatory) toward caspase-3-mediated apoptotic pathway (noninflammatory). SAMHD1 effectively suppresses caspase-1 activation and pyroptosis when infection occurs with cell-free virions. However, in the context of cell-to-cell transmission, which is 100-1,000-fold more efficient, SAMHD1 restriction is only partially effective resulting in the accumulation cytoplasmic viral DNA. This DNA is sensed by IFI16 resulting in caspase-1 activation and triggering of the pyroptotic death pathway. The action of other cellular factors like TREX1 and SLX4 (single and double strand DNA nucleases) may require further increase in the levels the cytosolic DNA needed to trigger pyroptosis.

Conclusions: 1. The Vpx protein thwarts inflammatory pyroptosis following HIV-2 infection by degrading SAMHD1 thereby avoiding abortive infection and sensing of cytosolic viral DNA.

2. SAMHD1 is a bifunctional host factor capably restricting infection of resting CD4 T cells by cell-free HIV virions but functioning as a pro-pathogenic factor when resting CD4 T cells are infected by HIV-1 by the cell-to-cell route.

203 Mapping Vpx and Vpr Specificity in Antagonism of SAMHD1

Chelsea Spragg; Michael Emerman

Fred Hutchinson Cancer Research Center, Seattle, WA, US

Background: The lentiviral accessory protein Vpx enhances infectivity of macrophages, dendritic cells, and resting T-cells by inducing degradation of the restriction factor SAMHD1, which blocks replication at reverse transcription. Vpx bridges SAMHD1 to the host ubiquitin ligase substrate receptor DCAF1, leading to polyubiquitination of SAMHD1 and degradation by the proteasome. The *vpx* gene is present in only two major lineages of lentivirus including HIV-2, but the paralagous *vpr* is present in all extant lineages. In certain cases, Vpr also has the ability to degrade host SAMHD1. SAMHD1 has evolved under positive selection due to viral antagonism, resulting in species-specificity between host SAMHD1 and viral Vpx/r. Depending on the lineage, Vpx exclusively targets either the N-terminus or the C-terminus of SAMHD1; however, the regions of Vpx/r controlling specificity are unknown. The structure of SIVmac Vpx bound to DCAF1 and the C-terminus of SAMHD1 has been solved, but there is extreme sequence diversity in *vpr* and *vpx* from divergent viruses.

Methods: We used an evolutionary and structural approach to find appropriate and robust breakpoints in Vpx and Vpr in order to create functional, chimeric viral proteins. By assaying for the gain of ability to degrade resistant SAMHD1, these chimeric proteins assisted in mapping of determinants of specificity in Vpx and Vpr from several lentiviral lineages.

Results: We found that the majority of residues involved in binding DCAF1 were conserved in essentially all SAMHD1-degrading Vpx and Vpr. We identified highly conserved amino acids flanking the regions of SIVmac Vpx involved in binding SAMHD1. These conserved motifs served as breakpoints to create chimeric proteins between Vpr and Vpx from SIVs infecting macaque, red-capped mangabey, and African green monkeys. We were then able to retarget Vpx and Vpr from different lentiviruses to degrade heterologous SAMHD1. Depending on the lineage, the specificity of Vpx/r in degrading SAMHD1 maps to one or two regions in the viral protein.

Conclusions: The structure of Vpx and Vpr proteins and their interaction with the host ubiquitin ligase is widely conserved, despite high levels of sequence variation across lineages. Given the evolutionary constriction in maintaining this ubiquitin ligase binding, similar regions of Vpr/x are used to target SAMHD1, allowing the mapping of sites that govern SAMHD1 antagonism in species-specific interactions.

204 Differentiation Stimuli Strongly Impact the Ability of Macrophages to Support HIV-1 Replication Due to SAMHD1 Restriction

Ester Ballana[1]; Roger Badia[1]; Eva Riveira-Muñoz[1]; Alba Ruíz[1]; Javier Torres-Torronteras[2]; Bonaventura Clotet[1]; Eduardo Pauls[1]; Ramon Marti[2]; José Esté[1]
HIV Pathogenesis Research Group
[1]IrsiCaixa Institute for AIDS Research, Badalona, Spain; [2]Institut de Recerca Hospital Universitari Vall d'Hebron, Barcelona, Spain

Background: Macrophages are a highly heterogenic cell population with cellular properties strongly influenced by the factors present during differentiation. Monocytes are refractory to HIV infection and only become susceptible to infection after differentiation, due to deactivation of the restriction factor SAMHD1 by phosphorylation. We have shown that SAMHD1 deactivation is controlled by cyclin-dependent kinases (CDK), which in turn, control cell activation and proliferation. Here, we used human primary monocyte-derived macrophages (MDMs) differentiated under different conditions to evaluate cell activation and proliferation, differential gene and protein expression patterns and susceptibility to HIV-1 infection.

Methods: CD14+ monocytes were differentiated with M-CSF or GM-CSF to generate M-CSF (M-MDM) or GM-CSF-induced MDM (GM-MDM). Expression of cell surface antigens and cell activation and proliferation markers was evaluated by flow cytometry. Susceptibility to HIV-1 infection was examined by flow cytometry after infection with a VSV-pseudotyped NL4-3 GFP-expressing virus in the presence or not of drugs targeting HIV or inhibiting cell activation or proliferation. SAMHD1 restriction was bypassed by VLP-containing Vpx. Gene expression was assessed by quantitative PCR and protein expression and phosphorylation by immunoblotting. dNTP levels were determined using a polymerase-based method.

Results: MDMs displayed different morphological characteristics dependent on the differentiation conditions, but no significant differences in cell surface antigens expression were observed. M-MDM were roughly 10-fold more susceptible to HIV-1 infection than GM-MDM, which correlated with higher dNTP levels in M-MDM compared to GM-MDM (from 3 to 80 fold difference depending on the nucleotide, being dCTP the lowest and dTTP the highest). Although no differences were found in SAMHD1 expression, a change in SAMHD1 activation was observed, as a consequence of different cell activation. Degradation of SAMHD1 by Vpx increased HIV replication in both cases, minimizing the original differences in susceptibility. Accordingly, SAMHD1 degradation led to an increase in dNTP intracellular levels under both conditions.

Conclusions: Differentiation strongly impacts the ability of MDMs to support HIV-1 replication, mainly due to SAMHD1 function determined by cell activation differences. These resultst suggest that the choice of macrophage model is important for evaluation of virus-cell interactions during HIV infection.

205 Essential Role of Cyclin D3 in dNTP Pool Control and HIV-1 Replication in Macrophages

Ester Ballana[1]; Alba Ruíz[1]; Eduardo Pauls[1]; Javier Torres-Torronteras[2]; Roger Badia[1]; Eva Riveira-Muñoz[1]; Bonaventura Clotet[1]; Ramon Marti[2]; José Esté[1]
HIV Pathogenesis Research Group
[1]IrsiCaixa Institute for AIDS Research, Badalona, Spain; [2]Institut de Recerca Hospital Universitari Vall d'Hebron, Badalona, Spain

Background: Cyclins control the activation of cyclin-dependent kinases (CDK), which in turn, control cell proliferation. We have shown that the virus restriction factor SAMHD1 is controlled by CDK6, a CDK controlling early G0 to G1 transition of the cell cycle. However, the cyclin controlling the process of SAMHD1 function has not been clearly identified in primary cells.

Methods: Monocytes were isolated and transfected with siRNA against different cyclins controlling cell cycle. Transfected monocytes were differentiated in macrophages using M-CSF. RNA interference was assessed by quantitative PCR and Western blot. Primary monocyte-derived macrophages (MDM) were infected with a VSV-pseudotyped NL4-3 GFP-expressing virus or full-replicative R5 HIV-1 strain BaL. Total viral DNA formation was quantified by qPCR and HIV replication measured by flow cytometry. SAMHD1 phosphorylation and protein expression were analyzed by immunoblotting. dNTP intracellular levels in siRNA-treated MDM were determined using a polymerase-based method.

Results: RNAi of eight distinct cyclins led to efficient and specific downregulation (up to 90% efficacy) of the corresponding cyclin as compared to mock-transfected cells or cells transfected with a non-targeting siRNA in MDM. Downregulation of the CDK6-associated cyclin D3 showed the strongest inhibitory effect ($p=0.0002$) of HIV-1 replication and total viral DNA formation in acutely infected MDM. Cyclins D1 and E2 (associated to CDK6 and CDK2, respectively) had a lower inhibitory effect. Cyclin A2, B1, B2 and D2 did not block HIV-1 replication. Alternative siRNA sequences targeting cyclin D3 confirmed the effect of cyclin D3 in HIV-1 infection and total viral DNA formation. Cyclin D3 downregulation led to a significant ($p<0.01$) reduction of SAMHD1 phosphorylation (at residue T592), CDK2 activation as measured by phosphorylation of T160 and decreased intracellular dNTP levels. The effect of cyclin D3 RNA interference was lost after degradation of SAMHD1 by HIV-2 Vpx.

Conclusions: Knockdown of cyclin D3 has a major impact in SAMHD1 phosphorylation, dNTP levels and HIV-1 reverse transcription and replication. Cyclin D3 is the catalytic partner of CDK6. Thus, our results indicate a fundamental role of the CDK6-cyclin D3 complex in SAMHD1-mediated virus restriction during G0 to G1 transition. Agents targeting cell proliferation may prevent new rounds of infection and hypothetically, might prevent the proliferation of persistently infected cells.

206 Low SAMHD1 Expression Renders Activated and Proliferated CD4$^+$ Susceptible to HIV-1

Nabila Seddiki[1]; Nicolas Ruffin[1]; Vedran Brezar[1]; Diana Ayinde[2]; Julian Schulze zur Wiesch[3]; Jan van Lunzen[3]; Olivier Schwartz[2]; Jean-Daniel Lelièvre[1]; Jacques Banchereau[1]; Yves Lévy[1]
[1]Inserm U955 Eq16/UPEC, Créteil, France; [2]Institut Pasteur, Paris, France; [3]University Medical Center, Hamburg-Eppendorf and Heinrich-Pette-Institute, Hamburg, Germany

Background: HIV-1 replication depends on the state of cell activation and division. It is established that SAMHD1 restricts HIV-1 infection of resting CD4$^+$ T cells. The modulation of SAMHD1 expression during T-cell activation and proliferation however remains unclear, as well as a role for SAMHD1 during HIV-1 pathogenesis.

Methods: SAMHD1 expression was assessed in CD4$^+$ T cells *ex vivo*, after their activation and *in vitro* HIV-1 infection. We performed phenotype analyzes and functional studies using CD4$^+$ T cells from peripheral blood and lymph nodes from cohorts of HIV-1 infected subjects under anti-retroviral treatment or not, and controls.

Results: We show that SAMHD1 expression decreased during CD4$^+$ T cell proliferation in association with an increased susceptibility to *in vitro* HIV-1 infection. Additionally, circulating memory CD4$^+$ T cells are enriched in cells with low levels of SAMHD1. These SAMHD1^{low} cells are highly differentiated, exhibit a large proportion of Ki67$^+$ cycling cells and are enriched in Th17 cells. Importantly, memory SAMHD1^{low} cells were depleted from peripheral blood of HIV-infected individuals. We also found that lymph node follicular helper T (Tfh) cells lacked the expression of SAMHD1, which was accompanied by a higher susceptibility to HIV-1 infection *in vitro*.

Conclusions: We demonstrate that SAMHD1 expression is decreased during $CD4^+$ T cell activation and proliferation. Also, $CD4^+$ T-cell subsets known to be more susceptible to HIV-1 infection, e.g. Th17 and Tfh cells, display lower levels of SAMHD1. These results pin point a role for SAMHD1 expression in HIV-1 infection and the concomitant depletion of $CD4^+$ T cells.

207 SAMHD1 Partially Blocks Lentiviral Gene Transfer Into Hematopoietic Stem Cells

Duo Li[1]; Erika Schlaepfer[1]; Annette Audigé[1]; Baek Kim[2]; Roberto Speck[1]
[1]*University Hospital Zurich, Zurich, Switzerland;* [2]*Department of Pediatrics Emory School of Medicine, Atlanta, GA, US*

Background: Understanding how to achieve efficient transduction of hematopoietic stem cells (HSCs), while preserving their self-renewing capacity, is key for applying lentivirus-based gene engineering methods in Phase I/II clinical trials. The sterile alpha motif (SAM) domain and HD domain-containing protein 1 (SAMHD1) was recently identified as a HIV-1 restriction factor in myeloid cells and resting $CD4^+$ T cells that interferes with reverse transcription by decreasing the nucleotide pools or by its RNase activity. HIV-2 and SIV have evolved to counteract the effects of SAMHD1 by their accessory protein Vpx, which targets SAMHD1 for proteasomal degradation. We hypothesized that SAMHD1 also interferes with HIV-1 vector-based HSCs transduction.

Methods: Expression of SAMHD1 in HSCs was quantified by western blotting and real-time quantitative PCR (qPCR). For HSCs transduction, we used HR-GFP-Vpx-/+ lentivirus, which carries Vpx and encodes GFP. Integrated provirus and viral DNA intermediates in HSCs and monocyte-derived macrophages (MDMs) were quantified by qPCR. Transduction efficiency was assessed by flow cytometry.

Results: Our results show that SAMHD1 is highly expressed in HSCs already at 2 hours culturing in a medium enriched with cytokines conventionally used for transduction of HSCs. In contrast, fresh HSCs have poor SAMHD1 expression. Expression levels of SAMHD1 in cultured HSCs are comparable to those found in MDMs. Following lentiviral based transduction with HR-GFP-Vpx+, we did not observe any increase of proviral DNA in HSCs while there was a significant one in MDMs which served as positive control for the assay. Similarly, there was a less than 3-fold increase of DNA intermediates in HSCs a vigorous one in MDMs. HSCs exposed to HR-GFP-Vpx+ showed a minor but significant increase in the number of GFP^+ cells which was associated with a decrease in SAMHD1 expression. GFP^+ cells were detected mostly within the population of cells containing low amounts of SAMHD1. There was an significant increase of the percentage of $GFP^+SAMHD1^-$ cells, while $GFP^+SAMHD1^+$ cells decreased 7 days post infection when compared to cells exposed to HR-GFP-Vpx- viral like particles.

Conclusions: HSCs cultured in cytokine-enriched medium, unlike uncultured cells, express high levels of SAMHD1. Vpx-mediated decreases of SAMHD1 expression levels enhances transduction rate in a minor sub-population of HSCs. The data imply that blocks mainly at cell entry are the major limiting step for efficient transduction.

Session P-A4 Poster Session **Poster Hall**

2:30 pm – 4:00 pm

Enhancers and Inhibitors of Viral Infectivity and Entry

208 Fresh Semen Harbors HIV-Enhancing Amyloids and Decreases the Efficacy of Microbicides

Jan Munch[3]; Onofrio Zirafi[3]; Shariq Usmani[3]; Kyeong-Ae Kim[3]; Frank Kirchhoff[3]; Christopher D. Pilcher[1]; Haichuan Liu[1]; H. Ewa Witkowska[1]; Warner C. Greene[2]; **Nadia R. Roan**[1]
[1]*University of California San Francisco, San Francisco, CA, US;* [2]*The J. David Gladstone Institutes, San Francisco, CA, US;* [3]*Ulm University Medical Center, Ulm, Germany*

Background: Semen, the most common vehicle for HIV transmission, enhances HIV infection *in vitro*. Previously, naturally-occurring peptides derived from the semen proteins prostatic acid phosphatase (PAP) and semenogelin (SEM) were shown to assemble into amyloid fibrils that markedly enhance HIV infection. Here, we investigated whether fresh semen samples contain these amyloids and affect the antiviral efficacy of various classes of microbicides.

Methods: Confocal microscopy, electron microscopy (EM), atomic force microscopy (AFM), quantitative mass spectrometry, ELISAs, and infection assays were used to detect, quantitate, and characterize endogenous HIV-enhancing amyloids in semen and to determine how semen affects the efficacy of microbicides.

Results: Endogenous PAP and SEM amyloids were detected in unmanipulated semen by immunogold EM, confocal microscopy, and AFM. These amyloids are present in semen from uninfected and HIV-infected individuals and directly bind HIV virions. The endogenous levels of these amyloidogenic fragments correlated significantly with the HIV enhancing activity of the semen samples, suggesting that they may be responsible for the ability of semen to enhance HIV infection. We also found that semen reduced the antiviral efficacy, by 10 to 20-fold, of multiple classes of antiretrovirals (ARVs) including neutralizing antibodies, NRTI's and NNRTI's, and inhibitors against Integrase and Protease. In striking contrast, semen deficient in amyloids did not enhance HIV infection or impair the antiviral activity of these ARVs. Notably, the sole microbicide that retained full activity in the presence of semen was Maraviroc (MVC), an HIV entry inhibitor that was the only microbicide investigated which targeted a host component instead of the virus itself.

Conclusions: Our results demonstrate that amyloids are abundant in fresh semen and that the ability of semen to enhance HIV infection markedly impairs the activity of microbicides targeting viral components. In contrast, MVC, which targets the cellular CCR5 entry cofactor, retained full activity in the presence of semen. Thus, compounds targeting cellular components may be advantageous for microbicide development. Our results may explain why most microbicides largely failed in clinical trials and suggest that inclusion of compounds that antagonize seminal amyloids will greatly enhance the efficacy of antiretroviral microbicides.

209 Semen's HIV Enhancing Activity Is an Individual Characteristic Independent of VL

Christopher D. Pilcher; Teri Liegler; Jason Neidleman; H. Ewa Witkowska; Wendy Hartogensis; Kara Marson; Peter Bacchetti; Frederick M. Hecht; Warner C. Greene; Nadia R. Roan
University of California San Francisco, San Francisco, CA, US

Background: Semen enhances HIV infection *in vitro*, and semen-derived amyloids made up of a peptide from the abundant protein semenogelin 1 (SEM1) are sufficient to mediate this activity. We sought to compare the infectivity-enhancing activity of semen among HIV infected men, and examine its relationship to concentrations of amyloidogenic peptides.

Methods: We studied 188 paired seminal and blood plasma samples from 113 individual UCSF Options study subjects at least four months after acute HIV infection. 20 subjects were studied at multiple timepoints prior to ART; 20 were studied before and after suppressive ART and 20 before and after ART interruption. Quantitative mass spectrometry and ELISAs were used to quantify amyloidogenic SEM peptide fragments. Semen-mediated enhancement of HIV infection was measured by mixing serial dilutions of each sample with HIV prior to adding it to TZM-bl reporter cells, and assessing infection levels by luminescence 3 days later. Seminal fluid VL was quantified using Abbott RealTime PCR.

Results: Semen from HIV infected men enhanced HIV infectivity (mean 10.8-fold, range from 0- to >35-fold enhancement). Levels of endogenous amyloidogenic SEM were correlated with the infectivity-enhancing activity of semen samples (r=0.48;p<.0001). For individual subjects with longitudinal samples, levels of both infectivity enhancement and SEM tended to be similar over time (intraclass correlations (ICCs) for infectivity enhancement 0.33, SEM 0.49, semen VL 0.42). Infectivity enhancing activity of semen had little association with ART naïve semen VL (r=-0.08). With interruption of ART (baseline semen VL<200 cp/mL in 18/20 subjects), there was no systematic increase in either infectivity enhancement (mean 18% decrease, p=0.17) or SEM (mean 13% decrease, p=0.054).

Conclusions: Our results suggest that semen from HIV infected men can enhance the efficiency with which HIV infects permissive cells, in a manner that persists in men taking ART and is independent of semen VL but is directly associated with levels of amyloidogenic SEM fragments. The HIV-enhancing activities of multiple semen samples from the same individual were relatively similar, even upon ART treatment, suggesting that the HIV enhancing activity of semen can be considered an individual characteristic. Together, these data suggest that individual semen characteristics other than HIV VL may be important factors in HIV transmission.

210 Hyaluronan Reduces HIV Infection of CD4+ T Cells and Greatly Enhances HIV Inhibition by Tenofovir

Peilin Li; Katsuya Fujimoto; Lilly Bourguignon; Steven Yukl; Steven Deeks; Philipp Kaiser; Peggy Kim; Diane Havlir; Harry Lampiris; Joseph K. Wong
University of California San Francisco, San Francisco, CA, US

Background: Better strategies are needed to prevent mucosal transmission of HIV. The major extracellular matrix receptorCD44, present on virion and target cells, has been reported to strongly influence viral infectivity. Topical formulations of antiviral drugs like tenofovir (TDF) are being studied in HIV prevention. We investigated how the natural ligand of CD44, hyaluronan, modulates HIV infection in vitro when used alone or with TDF.

Methods: HIV stocks were produced with or without CD44. Infection of cell lines (M7 Lue, TZM-bl) and of primary CD4+ T cells were performed with or without exogenous HA, inhibitors to HA signaling through PKCa, and TDF. Infection was gauged by RLU and p24 measurements. IC50 and IC95 of TDF were calculated. Significance was tested using a T-test.

Results: HA reduced HIV infectivity only when virions expressed CD44. HA inhibited HIV infection modestly and consistently in a dose dependent manner and removal of endogenous HA enhanced viral infectivity. Treatment with Gö6976, an inhibitor of PKCa, abrogated the effects of HIV to a degree similar to exogenous HA. Notably, co-treatment of cells with HA and tenofovir shifted TDF IC50 by greater than 1 log compared to TDF alone, while TDF IC95 was reduced by over 400 fold in the presence of HA. Similar findings were seen with R5 and X4 virus. HA was synergistic with the entry inhibitor T20 but to a lesser degree.

Conclusions: HA interacts with CD44 on virion and cell membranes to modulate HIV infection at the early (binding, entry) and post entry steps in the viral lifecycle. We found marked enhancement of antiviral effects of TDF by HA. Manipulation of CD44-HA interactions, used alone or together with antiviral drugs, deserves further study as a novel strategy to prevent transmission.

211 Alpha-defensins increase HIV transcytosis: role in STI-mediated enhanced HIV transmission

Kimyata B. Valere[1]; Aprille Rapista[1]; Alison Quayle[2]; Wuyan Lu[3]; Eliseo Eugenin[1]; Theresa Chang[1]
[1]Rutgers University-New Jersey Medical School, Willingboro, NJ, US; [2]University Health Science Center, New Orleans, LA, US; [3]University of Maryland School of Medicine, Baltimore, MD, US

Background: Although mucosal epithelial cells provide the first-line of defense against HIV infection, HIV can cross the genital or intestinal epithelium by transcytosis. The risk of HIV transmission is increased in individuals with Sexually Transmitted Infections (STIs). Defensins are antimicrobial peptides important for mucosal innate immunity. Alpha-defensins, including human defensin 5 (HD5) and human neutrophil defensins 1-3 (HNPs1-3), are elevated at the genital mucosa in individuals with STIs. HD5 promotes HIV infectivity and contributes to enhanced HIV infection by STIs in vitro. Unlike HD5, HNPs exhibit anti-HIV activity in vitro. However, enhanced HIV acquisition is associated with increased levels of HNPs in cervicovaginal fluid. In this study, we examined the effect of alpha-defensins on epithelial integrity and the subsequent impact on HIV transcytosis in polarized epithelial cells.

Methods: Defensins were added to the apical side of polarized intestinal epithelial (Caco) cells. Transepithelial electrical resistance was measured by cellZscope to monitor epithelial permeability. Distribution of tight junction markers was observed by immunofluorescent staining of ZO-1 or occludin. To examine HIV transcytosis, HIV-1_{BAL} was added to the apical side of polarized epithelial cells, and HIV that crossed to the basolateral side was measured by HIV p24 ELISA.

Results: HNP significantly increased epithelial permeability in a dose-dependent manner within 4 hours, suggesting transient HNP1-mediated epithelial disruption. However, HD5 at high concentrations slightly reduced TERs. Linear analogs of HNP1 and HD5 did not affect epithelial permeability, indicating that the impact of alpha-defensin on epithelial integrity is structure-dependent and not charge-dependent. Interestingly, both HD5 and HNP1 caused discontinuation and internalization of tight junction proteins in Caco cells. In agreement with their impact on epithelial permeability, HNP1, but not HD5, significantly increased HIV transcytosis in polarized intestinal epithelial cells.

Conclusions: Our results demonstrated that HNP1 and HD5 displayed distinct functions in facilitating transmission of HIV. Since HNP1 can alter the integrity of the mucosal epithelium leading to increased HIV transcytosis, defensin-mediated disruption of mucosal barriers offers a window of opportunity for HIV to invade the host. Our study provides a new role of HNP1 in STI-mediated enhancement of HIV transmission.

212 The Design and Investigation of Mechanism of Novel Potent HIV-1 Entry Inhibitor SC12

Marina Tuyishime; Simon Cocklin
Drexel University College of Medicine, Philadelphia, PA, US

Background: The process of HIV-1 entry is key to the replication of the virus and viral Env serves as a hot target as a first protein complex encountering the target cell. We designed a novel potent HIV-1 entry inhibitor, SC12 that binds viral Env and prevents the infection. In addition, SC12 has better predicted ADME/PK (absorption, distribution, metabolism and excretion/pharmacokinetic) properties compared to the lead chemotype in HIV-1 entry field, BMS compounds. Given the enormous potential of the small molecule entry inhibitor, SC12, we sought to investigate the mechanism of its action against HIV-1 viruses.

Methods: We utilized the single-round infection assay against HIV-1 viruses pseudotyped with HIV-1 Env and AMLV Env to identify the potency and specificity of SC12. Surface Plasmon Resonance (SPR) was employed to determine the binding site of SC12 on viral Env and to investigate its potential to block sCD4-gp120 binding. We designed a novel attachment assay based on the temperature dependence of entry to determine the effect of SC12 on viral attachment and viral fusion.

Results: SC12 has low nM to mid μM potency range against numerous isolates of HIV-1 clades A through D. In addition, SC12 was determined to directly bind gp120 and the gradual increase of SC12 concentration did not affect sCD4 binding to gp120. Moreover, SC12 did not block viral attachment to the cells regardless the time of the addition of the compound: before, after or at the time of the viral infection.

Conclusions: We have designed a novel small molecule inhibitor that is potent against various HIV-1 isolates proposing that the binding site of SC12 is conserved throughout the clades. We did not observe a concentration-dependent competition of SC12 and sCD4 for the binding site on gp120, proposing that SC12 is not an attachment inhibitor. Moreover, at the concentration of 70nM SC12 did not affect viral attachment to the cells, however, was able to inhibit over 50% of viral infectivity. Taken together, we propose that SC12 is not

an attachment inhibitor and blocks viral infection by other mechanism. The further characterization of its mechanism of action and optimization of SC12 will yield important basic information about the process of HIV-1 entry and potentially lead to the novel therapies.

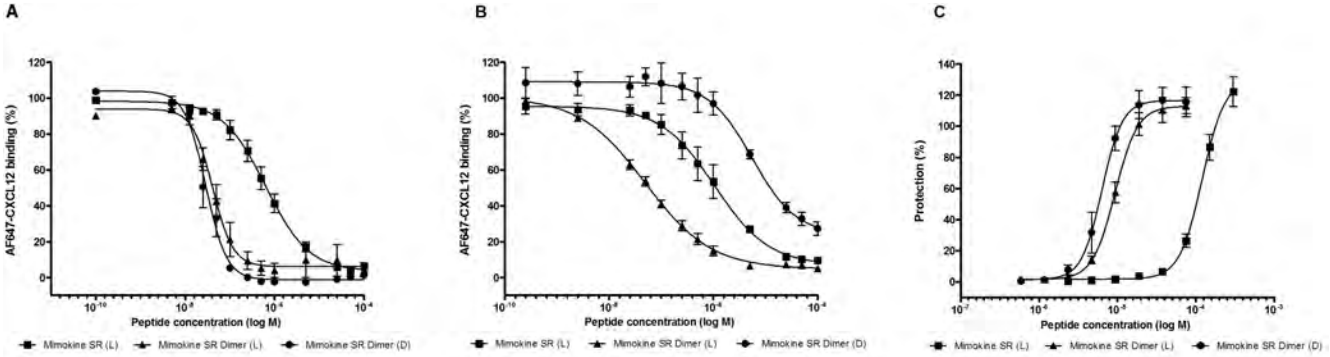
213 Optimization of vCCL2-Based CXCR4 Inhibitors by Phage Display and Rational Design

Virginie Fievez[1]; Martyna Szpakowska[1]; Karthik Arumugam[1]; Amor Mosbah[2]; Sabrina Deroo[1]; Xavier Dervillez[1]; Pierre-Arnaud Gauthier[1]; Michele Baudy-Floc'h[2]; Carole Devaux[1]; Andy Chevigné[1]
[1]CRP-sante, Laboratory of Retrovirology, 84 Rue Val Fleuri, 1526 Luxembourg, Luxembourg; [2]Université de Rennes 1, UMR CNRS 6226, Avenue du Général Leclerc, 35042 Rennes, France

Background: The viral broad spectrum chemokine vCCL2/vMIP-II binds to CXCR4 and CXCR7 and protects host cells against HIV-1 infection. Peptide derived from vCCL2 N-terminus ($vCCL2_{1-21}$) displays modest CXCR4 binding affinity and antiviral properties compared to the parental chemokine but mutations within its CC motif have been shown to enhance its antiviral properties. In this study, we selected new vCCL2 derived peptides by means of phage display and further optimized them by rational design

Methods: A $vCCL2_{1-21}$ phage library in which cysteine at positions 11 and 12 ($C_{11}C_{12}$) (Mimokine) were fully randomized was first engineered and screened against CXCR4-proteoliposomes. The most potent selected Mimokines were then further optimized by D-amino acid replacement and dimerization. Finally, a set of L- and D-bivalent ligands were evaluated for their CXCR4/CXCR7 binding and antiviral properties

Results: Selection of $vCCL2_{1-21}$ library on CXCR4 resulted in the isolation of 4 Mimokines bearing FR, SR, VR and WL residues at positions C_{11} and C_{12}. These Mimokines fully protected MT-4 cells against infection by a HIV-1 X4 virus (HXB2) (IC_{50} = 60 to 185 μM) and exhibited 3 to 4-fold higher affinity for CXCR4 (IC_{50} = 480 to 740 nM) than the reference Mimokine SS (IC_{50} = 2164 nM). Molecular modelling and docking into CXCR4 3D structure suggested that the enhanced affinity of Mimokines FR, SR and VR for CXCR4 might be due to the formation of an additional salt bridge between the Mimokine Arg12 and the receptor sulfated Tyr21. The potency of the selected Mimokines was further enhanced by combining dimerization and D-amino acid substitution. Bivalent Mimokines SR, VR, FR and WL in D format exhibited 10 to 20-fold increase in CXCR4 binding affinity (IC_{50} = 29 to 44 nM) and 20 to 100-fold increase in antiviral activities (IC_{50} = 1,8 to 6.3 μM) when compared to their respective monomeric L-counterparts. Interestingly, these bivalent D-Mimokines displayed a 100-fold reduction in binding CXCR7 (IC_{50} = 5630 nM) when compared to the bivalent L-Mimokines, demonstrating that D-amino acid replacement improved both affinity and selectivity for CXCR4



Binding and antiviral properties of monomeric and dimeric Mimokine SR in format D and L. The binding of Mimokine SR analogs to CXCR4 (A) or CXCR7 (B) expressing cells was assessed in competition experiments using a fluorescently labelled CXCL12 (AF647-CXCL12). Protection of MT-4 cells conferred by a 3-fold serial dilutions of Mimokine SR analogs against the HIV-1 HXB2 virus (C).

Conclusions: Optimized bivalent D-Mimokines displayed 10 to 20-fold enhanced CXCR4 affinity and 20 to 100-fold improved antiviral properties when compared to the initial monomeric L-Mimokines. These bivalent D-Mimokines showed a reduced affinity for CXCR7 and may therefore serve as lead compounds for the further development of more selective CXCR4 HIV-1 inhibitors

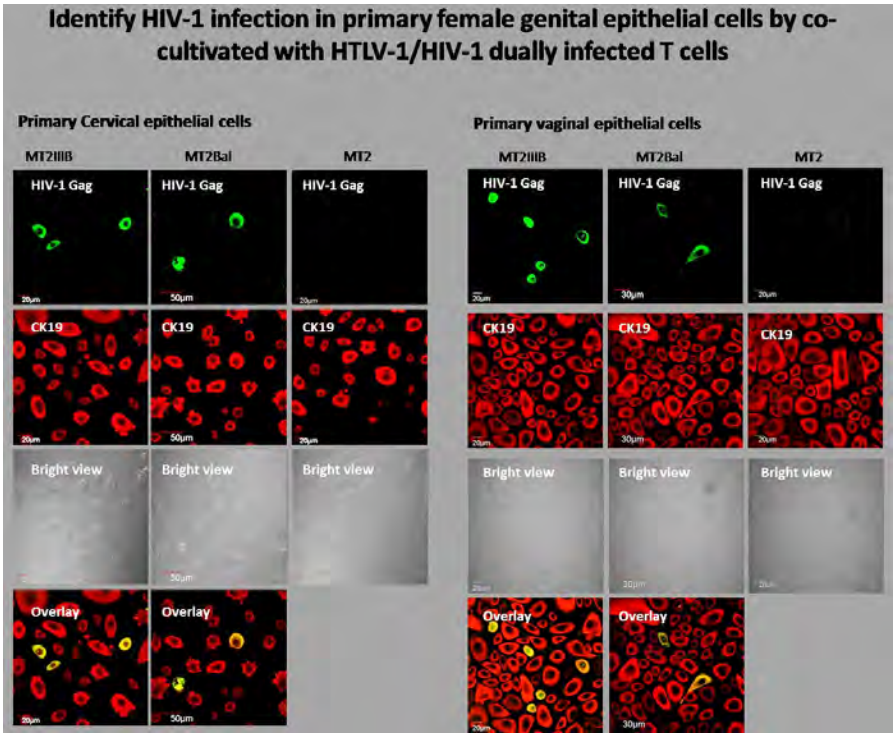
214 HIV-1 Infection of Female Primary Genital Epithelial Cells After Pseudotyping With HTLV-1: Potential Driver of Sexual Transmission of HIV-1

Yuyang Tang[1]; Alvin George[1]; Oksana Petrechko[1]; Brian Imbiakha[1]; Stephanie Sweet[1]; Yuetsu Tanaka[2]; Franklin Nouvet[1]; James E. Hildreth[1]
[1]University of California Davis, Davis, CA, US; [2]University of the Ryukyus, Nishihara-cho, Japan

Background: Young females are at high risk of HIV infection and constitute 75% of infected individuals in some sub-Saharan Africa countries. Some regions with high prevalence of HIV-1 are often also highly endemic for HTLV. HIV/HTLV co-infection in Africa, Latin America and the Caribbean basin is increasing and has emerged as a global health problem. In our recently published study we demonstrated that HIV-1 is able to acquire envelope glycoproteins of a gammaretrovirus during co-infection, in a process we called "natural pseudotyping", and expand its cellular tropism enabling it to infect primary female genital epithelial cells. Natural pseudotyping may dramatically increase risk of female HIV-1 infection during sexual intercourse and therefore could be a biological factor contributing to the devastating spread of HIV in young females in Africa and other regions of the world.

Methods: T cells were coinfected with both HIV-1 and HTLV-1. The progeny virus was exposed to primary vaginal and cervical epithelial cells. HIV-1 and HTLV-1 infection was measured by immunofluorescence staining with antibody anti-HIV-1 Gag antibody or anti-HTLV-1 Gag, the viral release from epithelial cells was measured by ELISA and qRT-PCR.

Results: Progeny virus from HTLV-1/HIV-1 co-infected T cells was capable of infecting primary vaginal and cervical epithelial cells via both cell-associated and free virus mediated infection. No HIV-1 infection was observed from epithelial cells exposed to progeny virus from T cells infected with HIV-1 alone. Infection of primary genital cells was significantly reduced by antisera against the HTLV-1 glycoprotein, indicating that HIV-1 infection was mediated by the HTLV glycoprotein. Active HIV-1 replication infection in primary genital epithelial cells was confirmed by inhibition with protease inhibitors. However, HIV-1 reverse transcriptase inhibitors AZT or Rilpivirine only partially blocked HIV-1 infection in primary genital epithelial cells. Further analysis indicated that AZT or Rilpivirine treatment blocked HIV-1 infection in cells infected with HIV-1 alone but not in cells infected by both HIV-1 and HTLV-1. Since AZT and Rilpivirine have very limited effects on HTLV-1 replication we conclude that HTLV-1 RT conferred resistance by HIV-1 to HIV-1 RT inhibitors.



Conclusions: Co-infection with HIV-1 and HTLV-1 produces naturally pseudotyped HIV-1 capable of directly infecting primary female lower genital epithelial cells and that the pseudotyped HIV-1 may be resistant to RT inhibitors.

Envelopes, Receptors, and Tropism

215 Evaluation of HIV-1 Clones for Unique Properties Associated With Transmission

Katja Klein[1]; Annette Ratcliff[2]; Gabrielle Nickel[2]; Immaculate Nankya[2]; Mike Lobritz[2]; Yong Gao[2]; Robin Shattock[3]; Eric J. Arts[1]

[1]*University of Western Ontario, London, Canada;* [2]*Case Western Reserve University, Cleveland, OH, US;* [3]*Imperial College London, London, United Kingdom*

Background: In the vast majority of cases, mucosal HIV-1 infection is initiated by a single infectious virus or a small number of HIV-1 virions. Next to CCR5 receptor usage and envelope glycosylation, little is known about the phenotypic properties of these transmitted HIV-1 virions and the influence that phenotype plays in the genetic bottleneck selection process. We evaluated a number of acute/early and chronic HIV-1 viruses, isolated from the female genital tract and blood, in a series of genotypic and phenotypic assays to determine differences that may influence transmission fitness.

Methods: We analyzed the genetic diversity by next generation sequencing of acute/early HIV-1 isolated from the female genital tract and compared it to the diversity of HIV-1 in blood of the same patients. We then engineered chimeric viruses from acute and chronic envelope genes and evaluated them for host cell entry efficiency and kinetics, receptor affinity, replication fitness, sensitivity to entry inhibitors and transmission using *ex vivo* human mucosal explant tissue.

Results: Genetic analysis revealed that acute/early HIV-1 isolates from blood are homogeneous while HIV-1 in the female genital tract showed high diversity. Furthermore acute isolates from the female genital tract displayed higher envelope glycosylation compared to HIV-1 from blood. We observed that both, acute and chronic HIV-1 isolates had similar entry kinetics, sensitivity to entry inhibitors and replicative fitness in primary cells. In contrast the evaluation of acute and chronic HIV-1 in human cervical and penile tissue clearly demonstrated that acute virions penetrate tissue, bind to residing DCs and establish infection of T cells more efficiently than chronic HIV-1, which were trapped and replicated in tissue. Higher transmission fitness of acute HIV correlated with reduced envelope N-linked glycosylation resulting in reduced lectin binding affinity.

Conclusions: Mucosal tissues, the major sites of heterosexual HIV transmission have high levels of extracellular soluble lectins and C-type lectins expressed on epithelial cells which are designed to prevent infection of high mannose-containing pathogens. As such, HIV-1 with reduced N-linked glycans may be passively selected for transmission by escaping the "lectin-trap".

216 Selection of HIV Env Mutants With Altered Trimers by EMPIRIC Saturation Mutagenesis

Maria Duenas-Decamp; Li Jiang; Dan Bolon; Paul R. Clapham

University of Massachusetts Medical School, Worcester, MA, US

Background: HIV-1 vaccines need to elicit neutralizing antibodies (nabs) that target conserved Env epitopes to protect against diverse HIV-1. To achieve this, we need to increase our knowledge on how different amino acids affect Env trimer structure. Native Env trimers are likely to be closed to protect against nabs and only triggered to open by CD4. Our hypothesis is that tightly closed trimers will (1) hide immunodominant non-neutralizing or strain specific Env sites e.g. V3 loop, and (2) expose conserved epitopes e.g. on the trimer association domain. To identify Env residues that maintain a closed trimer, we used EMPIRIC (Exceedingly Meticulous and Parallel Investigation of Randomized Individual

Codons) saturation mutagenesis. We created a library of viruses carrying every possible amino acid in an Env region downstream from the CD4 binding loop. Following fitness competition in PBMCs in the absence of immune pressure, we identified several mutations that facilitate trimer opening.

Methods: We used EMPIRIC saturation mutagenesis to create a plasmid library containing all possible mutations for aa 371-380 of LN40 Env in NL4-3 full length virus. We recovered viruses from transfected 293T cells and then infected PBMCs. To quantify competitive fitness, we measured the abundance of each mutant before and after PBMC infection using deep sequencing. We then studied 14 mutations that were selected at wt levels or higher in PBMCs. We evaluated changes in Env structure by testing the sensitivity of Env+ pseudovirions to neutralization by sCD4 and mabs b6, b12, 447-52D and 2G12.

Results: Substitutions at aa380 conferred sensitivity to CD4bs mab, b6 and V3 mab, 447-52D, which recognize more open trimers e.g. on laboratory strains. Substitutions at aa373, 375 in addition to 380 increased sensitivity to sCD4 compared to wt. Several substitutions conferred increased sensitivity to the CD4bs mab b12, with changes in residues 373 and 375 affecting b12, sCD4, 447-52D and 2G12 sensitivity together. Our data indicate that the residues identified play an important role in enhancing CD4 binding and/or regulating trimer opening.

Conclusions: We identified specific amino acids in a region of Env proximal to the CD4 binding loop that facilitate trimer opening, increasing the exposure of neutralizing epitopes and sensitivity to sCD4. The identification of specific positions in gp120 that affect trimer opening will help the design of stably closed trimers for use in vaccines.

217 Characterization of HIV-1 Envelopes in Acutely and Chronically Infected Injection Drug Users

Behzad Etemad[1]; Oscar A. Gonzalez[1]; Laura F. White[2]; Oliver B. Laeyendecker[3]; Greg D. Kirk[3]; Shruti Mehta[3]; **Manish Sagar**[1]

[1]Boston University School of Medicine, Boston, MA, US; [2]Boston University, Boston, MA, US; [3]Johns Hopkins University, Baltimore, MD, US

Background: Mucosally acquired HIV-1 infection results from a limited number of variants, and these infecting strains potentially have unique properties, such as increased susceptibility to entry blockers, relative interferon-alpha (IFN-α) resistance, and replication differences in some primary cells. There is no data about the phenotypic properties of HIV-1 envelope variants found early after acquisition among subjects infected through injection drug use (IDU).

Methods: We compared the characteristics of virus envelopes among injection drug users sampled prior to seroconversion (HIV RNA+/Ab-), within 1 year (early), and more than 2 years (chronic) after estimated acquisition. Full-length HIV-1 envelopes generated from pooling multiple bulk PCRs were incorporated into a HIV-1 NL4-3 backbone to create replication competent recombinant viruses. The envelopes were examined for various phenotypes, such as replication kinetics in primary cells, gut homing receptor, $\alpha4\beta7$, reactivity, and sensitivity to IFN-α. Summary phenotypic characteristics were compared using the Wilcoxon rank-sum test.

Results: Virus envelopes from 7 HIV RNA+/Ab- subjects possessed lower genetic diversity ($p = 0.05$) and divergence ($p = 0.05$) compared to 7 unrelated individuals sampled during the chronic phase of disease. The HIV RNA+/Ab- as compared to the chronic phase envelopes were significantly more sensitive to a CCR5 receptor inhibitor ($p = 0.03$) and IFN-α ($p = 0.008$) and showed a statistical trend toward greater sensitivity to a fusion blocker ($p = 0.07$). The early as compared to chronic infection envelopes also demonstrated a statistical trend or significantly greater sensitivity to CCR5 ($p = 0.06$) and fusion inhibitor ($p = 0.01$) and IFN- α ($p = 0.1$). The HIV RNA+/Ab- as compared to chronic envelope viruses replicated to a lower extent in mature monocyte derived dendritic cells – CD4+ T cell co-cultures ($p = 0.03$), but there were no significant replication differences in other primary cells, including those expressing high levels of the $\alpha4\beta7$ integrin, among the viruses with envelopes from the 3 different stages of infection.

Conclusions: Similar to mucosal acquisition, HIV-1 envelope quasispecies present in injection drug users prior to seroconversion have unique phenotypic properties compared to those circulating during the chronic phase of disease. This suggests that there is selection for specific HIV-1 variants during injection drug use.

218 Phenotypic Characterization of Transmitted/Founder Virus in HIV-1 Transmission Pairs

Corinna S. Oberle[1]; Beda Joos[1]; Nottania K. Campbell[1]; David Beauparlant[1]; Herbert Kuster[1]; Corinne Schenkel[1]; Peter Rusert[1]; Alexandra Trkola[1]; Karin J. Metzner[1]; Huldrych F. Günthard[1]

[1]University Hospital Zurich, Zurich, Switzerland; [2]Institute of Medical Virology, Zurich, Switzerland

Background: In 60-90% of mucosal HIV-1 transmissions a single transmitted/founder (T/F) virus from a genetically diverse virus population of the transmitter infects the recipient. Whether HIV-1 transmission is a stochastic process or the T/F viruses have beneficial features facilitating transmission and infection is controversially discussed. Here, we investigated the phenotypes of viruses isolated from transmission pairs in order to discover properties that might favor transmission.

Methods: Based on phylogenetic analyses of HIV-1 *polymerase* and *envelope* sequences and clinical data from patients enrolled in the Zurich Primary HIV-1 Infection Study (ZPHI) and Swiss HIV Cohort Study (SHCS), 9 potential transmission pairs of subtype B were identified and primary virus isolates of transmitter and recipient (acutely infected patients with single T/F virus) at the nearest time point of transmission were generated. Virus isolates were characterized in respect to replication capacity in peripheral blood mononuclear cells (PBMCs) in the absence and presence of IFN-α and in monocyte-derived macrophages (MDMs). Furthermore, sensitivity to different entry inhibitors (Maraviroc, DARPin 57.2, soluble CD4, T-20) and neutralizing antibodies (2G12, 4E10, 2F5), and the entry kinetics of these virus isolates were studied.

Results: All virus isolates replicated efficiently in PBMCs and 15 of 18 virus isolates were capable to replicate in MDMs, however, to a lesser extent. No clear pattern could be observed: In some transmission pairs, the virus isolate from the transmitter replicated more efficiently in MDMs and/or PBMCs and vice versa in other pairs. All virus isolates were sensitive to IFN-α; yet the degree to which replication was reduced varied within and between transmission pairs. In terms of entry, virus isolates from the same transmission pair were inhibited to similar degrees by different entry inhibitors and neutralizing antibodies. Moreover, virus obtained from transmitter and recipient showed similar entry kinetics.

Conclusions: For some transmission pairs, differences in replication capacities in both PBMCs in the absence or presence of IFN-α and MDMs were detected, yet we could not identify a common property shared by T/F viruses. T/F viruses and the virus population of the transmitter showed similar sensitivity to entry inhibitors/neutralizing antibodies and similar entry kinetics. Hence, according to the investigated parameters no signifying phenotypic pattern could be attributed to T/F viruses.

219 HIV Coreceptor Tropism Switching Is Correlated With Binding Affinity to CXCR4

Homero Vazquez[1]; Antoine Chaillon[2]; Douglas D. Richman[3]; Sara Gianella Weibel[1]; Gabriel Wagner[1]; David M. Smith[3]

[1]University of California San Diego, San Diego, CA, US; [2]Inserm UMR U966, Tours, France; [3]Veterans Affairs Medical Center, San Diego, CA, US

Background: The switch of HIV-1 co-receptor tropism from CCR5 (R5) to CXCR4 (X4) during the course of infection is associated with changes in the V3 region; however, little is known about the structural binding between V3 and R5 and X4 co-receptors during tropism switching. We used an *in-silico* approach to model the physical properties of the gp120-CD4-R5/X4 complexes during these changes.

Methods: A molecular dynamics (MD) and continuum-electrostatics poison-Boltzmann approach was used for generation of interaction models and calculation of binding affinity (BA). Since no experimentally derived structure is available, we first mapped well-characterized R5 and X4 strains onto the backbone of V3, followed by molecular dynamic simulations and docking of simulated structures into R5 and X4 to generate a gp120-CD4-R5/X4 complex interaction model. A database of viral sequences (n= 42 sequences, 38 from macaques, and 4 from patients) that switched over time from R5 to X4 tropism was then utilized to investigate changes in BA during tropism switching. All sequences were modeled onto the backbone structures of the interaction models of both R5 and X4; and BA amongst gp120, CD4, and R5/X4 was also calculated.

Results: When comparing the gp120-CD4-R5 complex in R5 tropic virus to the gp120-CD4-X4 complex in X4 tropic virus, the higher charge on the V3 associated with X4 tropism led to greater thermodynamic stability via favorable electrostatic interactions in the gp120-CD4-X4 complex than V3 that was tropic to R5. Cross-sectional analysis of X4 tropic versus R5 tropic sequences identified a significant correlation between the BA of gp120 to CD4+X4 ($p<0.001$) but not between the BA of gp120 to CD4+R5 ($p=0.35$). In longitudinal analysis, switching tropism from R5 to X4 was associated with a significant decline in BA between gp120 to CD4+R5 by 52%-76% and a concomitant increase in BA between gp120 to CD4+X4 by 0.4%-29.3%.

Conclusions: Structural modeling demonstrated that X4 tropism is highly associated with the BA of gp120 to CD4+X4, while R5 tropism is not associated with the BA between gp120 and CD4+R5. Further, when a viral population switches from R5 to X4 tropism, the thermodynamic stability of the gp120-CD4-X4 complex considerably increases while the thermodynamic stability of the gp120-CD4-R5 complex decreases. Together, these data provide new insights into the mechanisms of viral co-receptor interaction and co-receptor tropism switching.

220 Selective Cell-Free or Cell-to-Cell HIV-1 Infection by gp41 Cytoplasmic Tail Mutants

Natasha D. Durham[1]; Benjamin K. Chen[1]

[1]Icahn School of Medicine at Mount Sinai, New York, NY, US; [2]Icahn School of Medicine at Mount Sinai, New York, NY, US

Background: The gp41 transmembrane subunit of the HIV-1 envelope (Env) has a cytoplasmic tail (CT) ~150 amino acids (aa) long. The CT has several functions during the viral life cycle, including the i) endocytosis of cell-surface Env ii) packaging Env into viral particles and iii) controlling the fusogenic potential of Env. Full truncation of the gp41 CT (ΔCT144) does not directly impair viral fusion and can generate infectious virus in a cell-type dependent manner. Smaller deletions result in non-infectious virus particles, although Env is still expressed and packaged. Only the full truncation, ΔCT144, has been tested in the context of cell-to-cell infection. We therefore set out to systematically examine which domains of the CT are required for cell-to-cell infectivity in comparison to those needed for cell-free infection.

Methods: We constructed a series of truncation mutants that remove three major structural motifs in the gp41 CT, LLP-1, LLP-3 and LLP-2. Mutants were examined for HIV-1 envelope expression levels on the surface of transfected T-cells and total Env levels packaged onto virus particles. We used flow-cytometry to assess the single-round infectivity of cell-free and cell-associated virus in MT4 and primary CD4+ T-cells.

Results: Small truncations ≤43 aa that remove LLP-1 severely impaired the infectivity of cell-free virus, while cell-to-cell infection remained ~50% as infectious as WT HIV-1. Similar selective deficiency in cell-free but not cell-to-cell infection was observed with the LLP-3 point mutants. Conversely, large truncations ≥93 aa severely impaired cell-to-cell infectivity while maintaining infectious viral particles. Intermediate truncations (59-90 aa) showed profound impairment of both modes of infection.

Conclusions: We identified gp41 CT mutants with striking selective deficiencies in cell-free but not cell-to-cell infectivity, or vice versa. Our results indicate that functional properties of Env required for cell-free and cell-to-cell infection are genetically distinct. These differences may reflect a different intrinsic regulatory influence of the CT on cell-associated versus particle-associated Env, or differential interaction with host or viral proteins. Our findings highlight the positive and negative potential of the gp41 CT in regulating cell-free and cell-to-cell HIV-1 infection. We will use these mutants in future studies to define the contributions of cell-free and cell-to-cell infection *in vivo*, and to study one mode of infection in isolation.

221 Analysis of Viral Evolution in the Blood Reveals Potential Insight Into the Evolution of Macrophage Tropism

Maria M. Bednar[1]; LiHua Ping[1]; Kathryn Arrildt[1]; Christa Sturdevant[2]; Sarah B. Joseph[1]; Laura Kincer[1]; Celia LaBranche[2]; David Montefiori[2]; Myron Cohen[3]; Ronald Swanstrom[1]

[1]University of North Carolina, Durham, NC, US; [2]Duke University, Durham, NC, US; [3]University of North Carolina, Chapel Hill, NC, US

Background: Understanding the evolution of entry phenotype of HIV-1 is essential for our understanding of HIV-1 pathogenesis, latency, and disease progression**.** The use of a more precise assay to define entry phenotype based on the ability of HIV-1 to use low levels of CD4 for efficient entry has clarified the relationship of viruses that have evolved to infect macrophages as distinct from R5 viruses that predominantly replicate in T cells. We have used this assay to identify infrequent examples of macrophage-tropic (M-tropic) viruses and partially M-tropic viruses (intermediate) in cerebral spinal fluid and genital tract. However the prevalence of M-tropic viruses in other compartments, such as the blood, remains unknown. We set out to determine if M-tropic viruses ever reach a point of systemic infection.

Methods: Viral RNA was isolated from blood plasma samples from viremic subjects infected with either subtype B or subtype C HIV-1, and with CD4+ T cell counts of <100 cell/mm^3. Individual *env* gene were isolated, cloned and analyzed for receptor usage using Affinofile cells, in order to determine the viral entry phenotype. Susceptibility of pseudoviruses to soluble CD4 was also evaluated.

Results: 18 subtype B and 20 subtype C late-stage infected subjects were examined. As expected for late stage subjects, we identified X4 lineages in over 50% of the subjects. To date, no examples of efficient use of low CD4 for entry (M-tropic virus) have been found in the blood. However, we do occasionally see a level of infection on CD4-low cells that is marginally greater than that of the typical R5 T cell-tropic virus. This intermediate phenotype has also been seen in the CSF and genital tract. This new group of viruses showed increased sensitivity to soluble CD4 that is comparable to macrophage-tropic viruses.

Conclusions: Using the definition of M-tropic virus as the ability to utilize low levels of CD4, leads to the conclusion that these variants are rare and are potentially limited to specific compartments of the body. The appearance of intermediate phenotypes in the blood argues that there may be some evolution toward macrophage tropism taking place in compartments that shed virus into the blood late in disease. The high level of sensitivity to soluble CD4 among intermediate viruses suggests that the evolution to M-tropism is at least a two-step process where the viruses first become more sensitive to interaction with CD4 followed by more efficient fusion.

222 Mechanistic Differences in Interactions of HIV-1 and HIV-2 With Dendritic Cells

Suzanne D. Kijewski; Hisashi Akiyama; Caitlin Miller; Nora P. Ramirez; Rahm Gummuluru

Boston University School of Medicine, Boston, MA, US

Background: HIV-2 infection has been restricted predominantly to West Africa; in contrast HIV-1 has spread rapidly and accounts for 95% of all HIV infections globally. Interestingly, HIV-2 infected individuals maintain low viral loads and have lower mortality rates than HIV-1 infected individuals. The mechanistic basis for viral control and slower progression to AIDS in HIV-2 infected individuals remains unclear. We hypothesized that reduced interaction of HIV-2 with CD169, the primary HIV-1 attachment factor on myeloid dendritic cells (DCs) that targets captured virus particles to the trans infection pathway, plays an important role in its restricted pathogenesis.

Methods: We constructed an HIV-2 proviral plasmid that encodes GFP between MA and CA and flanked by protease cleavage sites (HIV-2-iGFP), such that infectious virions contain GFP, similar to the previously described HIV-1-iGFP proviral clone (*J. Virol. 2007, 81:12596*). To examine interactions of HIV-2 with CD169, THP1 cells constitutively expressing CD169 (THP1/CD169) were pulsed with HIV-1iGFP or HIV-2iGFP virions and virus capture in the presence or absence of αCD169 blocking antibodies was determined by flow cytometry. Intra-cellular localization of HIV-1-iGFP or HIV-2-iGFP within mature DCs was determined by immunofluorescence microscopy. To determine access of HIV-2 to the CD169 mediated trans infection pathway, mature DCs were exposed to GFP-expressing single-cycle of replication competent HIV-2 virus pseudotyped with HIV-2 Env, and then co-cultured with autologous CD4$^+$ T cells.

Results: We have previously shown that HIV-1 evades cell-intrinsic restrictions in DCs by exploiting CD169 for enhanced transfer to $CD4^+$ T lymphocytes. Interestingly, there was a 3-fold reduction in capture of HIV-2 compared to HIV-1 by THP1/CD169 cells. Similar reduction in CD169 specific capture is seen with mature DCs, though both HIV-1 and HIV-2 virions were localized following capture within a $CD81^+$ compartment. Though HIV-1 and HIV-2 are equally infectious for $CD4^+$ T cells, there was a 7-fold decrease in mature DC-mediated HIV-2 trans infection of $CD4^+$ T cells compared to HIV-1 suggesting that HIV-2 might interact with additional receptors on the mature DC surface, which inhibit access to the trans-infection pathway.

Conclusions: We conclude that a reduced interaction of HIV-2 with CD169 inhibits access of HIV-2 to the DC-mediated trans infection pathway and might result in attenuated dissemination in vivo.

223 Identification of the First Nonhuman Primate CD4 Receptor for T/F HIV-1 Isolates

Nicholas Meyerson[2]; **Amit Sharma**[1]; Gregory Wilkerson[3]; Julie M. Overbaugh[1]; Sara Sawyer[2]

[1]Fred Hutchinson Cancer Research Center, Seattle, WA, US; [2]The University of Texas at Austin, Austin, TX, US; [3]University of Texas, MD Anderson Cancer Center, Bastrop, TX, US

Background: Nonhuman primate species are resistant to HIV-1 infection, in most cases due to the inability of their CD4 to function as HIV-1 receptor for viral entry and/or species-specific host factors that restrict HIV-1 replication. Envelopes (Envs) from lab-adapted and some chronic-stage isolates of HIV-1 use the CD4 receptor encoded by multiple primate species, including macaque CD4. However, only the human CD4 receptor can mediate entry of Envs from HIV-1 variants representing transmitted/founder (T/F) viruses, which are most relevant to the HIV-1 pandemic. CCR5 presents an additional barrier to entry in many other primate species. These factors have limited the development of animal models to study viral pathogenesis of these more clinically relevant, T/F HIV-1 strains.

Methods: In this study we analyzed the CD4 sequence of multiple individuals from 11 different nonhuman primate species, including two Old World macaque species and five different species of New World monkeys. We also utilized human SNP databases and previous reports on *CD4* diversity in chimpanzees and three different species of Old World monkeys. We cloned selected *CD4* and *CCR5* alleles from primate species that were polymorphic at sites identified in previous studies as critical for HIV-1 envelope binding and/or entry. We tested these *CD4* and *CCR5* alleles for their ability to function as HIV-1 receptor and coreceptor, respectively, by generating cells expressing different combinations of these receptors.

Results: Multiple *CD4* alleles were identified in one New World monkey species, the Spix's owl monkey (*Aotus vociferans*), which encode CD4s that support entry mediated by circulating Envs from all of the major clades of HIV-1 group M. The Spix's Owl monkey CD4 receptor facilitated entry at levels similar to the human receptor in combination with human CCR5 and pig-tailed macaque CCR5. Interestingly, CCR5 from Spix's owl monkey was not a functional coreceptor when combined with their permissible CD4.

Conclusions: We demonstrate that CD4 is polymorphic in primate species at sites critical for HIV-1 entry. We have identified the first nonhuman primate CD4 compatible with entry of transmitted, circulating HIV-1 Envs. These findings support efforts to use novel strategies, including genetic screening, for developing better HIV-1 animal models.

224LB Vpr Increases Env Spikes on Virions to Enhance HIV-1 Replication in Nondividing Myeloid Cells

Tao Zhou[1]; Xianfeng Zhang[2]; **Yonghui Zheng**[1]

[1]Michigan State University, East Lansing, MI, US; [2]Harbin Veterinary Research Institute, Harbin, China

Background: Vpr plays an important role in maintenance of high viral load and disease progression *in vivo* through unknown mechanisms. Vpr has a very important function *in vitro*, enhancing viral replication in non-dividing myeloid cells, but the mechanism is likewise unknown. Because these cells are primary targets for HIV-1 infection and contribute to viral persistence, understanding how Vpr enhances HIV-1 replication *in vitro* is critically important to understanding the functional role of Vpr *in vivo*. Notably, Vpr is packaged into HIV-1 particles at large numbers via a specific interaction with Gag, and Vpr activates the oxidative stress pathway in mammalian cells and fission yeast. However, it is still unknown how these Vpr activities contribute to the enhancement of viral replication.

Methods: Previously, we identified a human T cell line CEM.NKR (NKR), where we reported that Vpr is absolutely required for HIV-1 replication. We also reported that Env is misfolded and rapidly degraded via the ER-associated protein degradation (ERAD) pathway in these cells. We then investigated HIV-1 replication, Env expression, and Env incorporation in NKR cells, monocyte-derived macrophages (MDM), and monocyte-derived dendritic cells, after creating a panel of Vpr mutations in HIV-1 proviral constructs. We also compared how Env was degraded in the presence or absence of Vpr by activating the oxidative stress pathway and/or inhibiting the ERAD pathway.

Results: It was found that when Vpr was not expressed, Env was more aggressively degraded via the ERAD pathway. Vpr could strongly block this degradation, resulting in significant increase of Env expression. A single A30L mutation within the 1^{st} α-helix of Vpr could disrupt this activity, suggesting that the N-terminal region of Vpr plays a critical role in Env expression. Interestingly, although Env could be expressed, it was not efficiently incorporated into virions unless Vpr was expressed. However, Vpr was not required for Env trafficking to the cell surface. Using Vpr packaging deficient mutants, it was further uncovered that the Env incorporation was dependent on the Vpr incorporation. Importantly, Vpr was found to interact with both Gag and Env, resulting in increase of Env incorporation.

Conclusions: We concluded that Vpr increases Env expression likely by promoting Env folding via the oxidative stress pathway, and it also increases Env incorporation via bridging Env with Gag, resulting in increase of Env spikes on virions and enhancement of HIV-1 replication.

Session P-A6 Poster Session **Poster Hall**

2:30 pm – 4:00 pm

Nef Functions

225 Env and Nef Cooperatively Contribute to HIV-1–Induced pDC Activation via CD4-Dependent Mechanisms

Natalia J. Reszka-Blanco[1]; Vijay Sivaraman[1]; Liguo Zhang[2]; Lishan Su[1]

[1]University of North Carolina, Chapel Hill, NC, US; [2]Key Lab of Infection and Immunity, Insitute of Biophysics, Chinese Academy of Science, Beijing, China

Background: HIV-1 infection induces high levels of type I IFN (IFN-I). The function of IFN-I in HIV-1 infection is not entirely defined, with results showing either its beneficial effect in anti-vial therapy or contribution to the HIV-1 related immune activation and CD4 T cell loss. Moreover, HIV-1 early isolates are resistant to IFN-I control and can succeed in establishing systemic infection despite the high level of IFN-I. Plasmacytoid dendritic cells (pDC) are the major source of IFN-I and play a critical role in the response to HIV-1. pDC are rapidly activated by HIV-1 infection and are implicated in both early reduction of viral load and HIV-1 induced pathogenesis. Interestingly cell-free virions of most HIV-1 isolates

are relatively weak stimulants of pDC and the mechanism of HIV-1 recognition by pDC and pDC activation is not clearly defined. Using two HIV-1 isolates, designated R3A and R3B, we aimed to determine the critical elements of the HIV-1 viral particle required for IFN-I induction in pDC.

Methods: Human PBMC and pDC were used to study the IFNa induction. IFNa was measured by Elisa. Viral production was quantified by p24-Elisa. Ala-substitution mutagenesis was used to analyze the Nef-functional domains.

Results: In this study we showed that two highly similar HIV-1 variants isolated from a rapid progressor had distinct activity to stimulate pDC and induce IFNa, which in turn correlated with their relative pathogenic activity. The highly pathogenic HIV-1 isolate R3A induced robust IFNa production in pDC, while R3B did not. The viral determinant of efficient IFNa induction was mapped to R3A Env and its V1V2 region with enhanced CD4 binding activity. Interestingly, the Nef gene in R3A was also required for the IFNa induction from pDC. To define which Nef domain or activity are required for increased IFNa induction, we analyzed a panel of R3A Nef functional mutants. We showed that Nef domains involved in CD4 downregulation are necessary for R3A to induce IFNa in pDC.

Conclusions: Our data indicate that HIV-1 induced pDC activations depends on (1) the efficacy of envelop to bind CD4 receptor and (2) the Nef activity involved in CD4 downregulation. Our work provides new insights into the mechanism by which HIV-1 stimulates IFNa in pDC and describes novel function of Nef protein which contributes to increased IFNa production and therefore to the pathogenesis of HIV-1 infection.

226 Naturally Occurring Polymorphisms in HIV-1 Nef Impair Its Functions and Decrease Viral Replication Capacity

Thomas Vollbrecht[2]; Lorelei Bornfleth[1]; Patricia Frohnen[1]; Martha J. Lewis[1]

[1]David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA, US; [2]University of California San Diego (UCSD), La Jolla, CA, US

Background: The multifunctional accessory HIV-1 protein Nef plays a pivotal role in viral pathogenesis. Key functions of Nef include the downregulation of CD4 and MHC class-I molecules from the surface of HIV-1 infected cells. Previously, we have identified new polymorphisms in Nef from nine subjects under selection pressure by HIV specific CTL. Here we investigate the effect of these polymorphisms on the ability of Nef to downregulate CD4 and MHC class-I molecules, as well as the impact of these polymorphisms on viral replication capacity.

Methods: The polymorphisms N52A, N52S, A84D, Y135F, G140R, S169I, H171N, H171P, H71G, D175E, D175N, and V180E were created individually within the plasmid AA1305, a NL43-based proviral vector with the murine CD24 (HSA) reporter gene in vpr, to generate VSV-G pseudotyped replication defective reporter viruses. Additionally, we introduced these mutations into the plasmid p8310, a NL4-3 based half-genome plasmid to generate replication competent reporter viruses. CEMx174.T1 cells were transduced with the replication defective individual viruses to determine the downregulation of MHC class-I and CD4 by flow cytometry. Viral replication capacity was assessed using gDNA and qPCR from PBMC transduced with replication competent reporter viruses.

Results: We found in total seven polymorphisms (N52S, A84D, Y135F, G140R, S169I, H171N, H171P) resulting in a significant reduction of HLAA*02 downregulation and five polymorphisms (A84D, G140R, S169I, H171N, H171P) with a significant decrease in CD4 downregulation compared to wild type NL4-3 Nef. Nef with either of two polymorphisms, A84D and G140R was defective for downregulation of HLA-A*02 and CD4. Additionally, virus with the G140R polymorphism also exhibited a significantly decreased viral replication capacity.

Conclusions: Our study shows that the majority of the tested polymorphisms exert an inhibitory effect on Nef's functions. The two polymorphisms A84D and G140R block CD4 and MHC class-I downregulation by Nef. Additionally, the G140R polymorphism also results in a decreased viral replication capacity in primary cells. All tested variants were natural occurring polymorphisms that were previously identified in primary isolates.

Our findings lead the way for better Nef targeting by vaccines and for the development of highly effective Nef inhibitors. These results demonstrate new potential targets for immunization or pharmacological intervention strategies.

227 Dynamic Range of Down-Regulation of HIV-1 Entry Receptors by Primary Nef Isolates

Mako Toyoda[1]; Yoko Ogata[1]; Macdonald Mahiti[1]; Florencia Pereyra[3]; Toshiyuki Miura[2]; Bruce Walker[3]; Zabrina L. Brumme[4]; Mark A. Brockman[4]; Takamasa Ueno[1]

[1]Kumamoto University, Kumamoto, Japan; [2]University of Tokyo, Tokyo, Japan; [3]Ragon Institute of MGH, MIT and Harvard University, Cambridge, MA, US; [4]Simon Fraser University, Burnaby, Canada

Background: HIV-1 Nef down-regulates the viral entry receptor CD4 as well as the co-receptors CCR5 and CXCR4 from the surface of infected cells, leading to promotion of viral replication through super-infection resistance and other pathways. In vitro mutagenesis of laboratory strains have identified various sequence motifs within Nef that modulate these functions. However, it remains unclear whether primary Nef sequences isolated from patients with different disease status also modulate down-regulation of these receptors via these same sequence motifs.

Methods: Nef clones were amplified from plasma viral RNA of 45 elite controllers (EC) and 46 chronic progressors (CP) and cloned into an expression plasmid. Additional mutations and reversions were introduced into these primary Nef clones to identify functionally important residues and motifs. The resultant plasmids were transfected into TZM-bl cells and CEM cells. Steady-state Nef expression level and cell surface expression of viral receptors were analyzed by Western blot and flow cytometry, respectively.

Results: Nef clones from EC showed significantly impaired activity in down-regulation of CD4 and CCR5, compared to those from CP ($p<0.001$), whereas the difference in down-regulation activity of CXCR4 was not statistical significance ($p=0.05$). The ability to down-regulate CD4 and CCR5 correlated positively in both EC and CP ($R>0.7$, $p<0.001$), suggesting that both activities are simultaneously required in vivo. Nef codon-function analyses failed to identify residues significantly associated with Nef functions. Instead, mutagenesis studies on three EC Nef clones showing substantially diminished functions revealed that multiple residues were involved in altered Nef functions and protein expression level. Specifically, polymorphisms at the highly conserved tryptophan residues (e.g., Trp-57 and Trp-183) and within known CTL epitope regions were responsible for reduced Nef functions in these clones.

Conclusions: Reduced ability of Nef to down-regulate viral entry receptors appear to be mediated by multiple sequence motifs in primary Nef isolates, including those not identified in in vitro mutagenesis studies. Very rare polymorphisms as well as polymorphisms at immune-reactive sites were involved in this phenomenon in EC. Results suggest that functional attenuation of Nef in EC is mediated by complex polymorphism networks in individual Nef sequences.

228 Differential Down-Regulation of HLA Class I Allotypes by HIV-1 Nef Primary Isolates

Macdonald Mahiti[1]; Xiaofei Jia[2]; Mako Toyoda[1]; Francis Mwimanzi[1]; Bruce Walker[3]; Zabrina L. Brumme[4]; Mark Brockman[4]; Yong Xiong[2]; **Takamasa Ueno**[1]

[1]Kumamoto University, Kumamoto, Japan; [2]Yale University, New Haven, CT, US; [3]Ragon Institute of MGH, MIT and Harvard University, Boston, MA, US; [4]Simon Fraser University, Burnaby, Canada

Background: HIV-1 Nef, in conjunction with the host adaptor protein 1 (AP1), binds to the cytoplasmic region of HLA-A and HLA-B molecules and down-regulates them from the cell surface, thus allowing virus-infected cells to evade immune detection. Polymorphic residues within the HLA class I cytoplasmic region may affect Nef binding and subsequent down-regulation. However, the impact of HLA polymorphisms on recognition by primary Nef isolates, and the specific Nef regions responsible for flexible or differential down-regulation of various HLA-A and HLA-B molecules remain incompletely known.

Methods: 46 Nef clones isolated from chronically HIV subtype B-infected subjects were analyzed for down-regulation of HLA-A, HLA-B, and HLA-C on the surface of virus-infected cells by flow cytometry. A set of cells singly expressing various HLA class I alleles (HLA-A2, A24, A33, B35, B57, and Cw4) and a T cell line endogenously expressing multiple HLA class I, including HLA-A2 and HLA-B51, were analyzed.

Results: In 46 primary Nef clones, HLA-B showed greater resistance to Nef-mediated down-regulation compared to HLA-A ($p<0.001$), regardless of cell type examined. No Nef clone down-regulated HLA-C. A Nef codon-function analysis revealed that amino acid variations at Nef-202 substantially affected Nef-mediated HLA-A and HLA-B down-regulation function; this was subsequently confirmed by site-directed mutagenesis. Specifically, the Tyr-202 to Glu mutation alone was sufficient to selectively impair Nef-mediated HLA-B down-regulation. Moreover, a crystal structure of the ternary complex of Nef, HLA-A2 cytoplasmic tail peptide and the mu1 subunit of the host AP1 revealed that Nef-202 is in close proximity to the end of the HLA-A cytoplasmic tail where HLA-B lacks three amino acids compared to HLA-A, suggesting that this Nef residue may play a role in increased binding to the HLA-A cytoplasmic tail and facilitating down-regulation.

Conclusions: Taken together, results indicate that natural sequence variability within HIV-1 Nef affects the interaction with polymorphic HLA class I cytoplasmic tails for down-regulation, providing us with further insight into this complex pathway of immune evasion.

Session P-B1 Poster Session — Poster Hall

2:30 pm – 4:00 pm

Viral Origins and Recombinant Forms

229 Geopolitical Effects in the Epidemiology of HIV-1 Subtype

Gkikas Magiorkinis[2]; Kostantinos Angelis[1]; Ioannis Mamais[1]; Angelos Hatzakis[1]; Jan Albert[3]; Glenn Lawyer[4]; Annemarie Wensing[5]; Charles Boucher[6]; Anne-Mieke Vandamme[7]; **Dimitrios Paraskevis**[1]

[1]University of Athens, Athens, Greece; [2]University of Oxford, Oxford, United Kingdom; [3]Karolinska Institutet, Stockholm, Sweden; [4]Max Planck Institute for Informatics, Saarbrücken, Germany; [5]University Medical Center Utrecht, Utrecht, Netherlands; [6]Erasmus University Medical Center, Rotterdam, Netherlands; [7]KU Leuven, Leuven, Belgium

Background: HIV-1 was discovered in the early 1980's when the virus had already established a pandemic. For at least three decades the epidemic in the Western World has been dominated by subtype B infections. Initially, the virus travelled from Africa through Haiti to the USA.

Methods: We assembled a globally representative dataset of HIV-1 subtype B sequences (N=8,370), by pooling molecular data collected from patient-cohorts and systematically selected molecular epidemiology studies from around the world. We analyzed the sequences using statistical phylogeography run on 250 bootstrap trees. To date, this is the largest global phylogeographic study of subtype B.

Results: We found that North America provided an active hub of dispersal for most local epidemics globally, while Western Europe also received infections from most of the other regions, namely from North and Central/South America, the Caribbean, Africa and Oceania. Significant migration events from Africa and Oceania to Europe, suggests that only a small number of subtype B infections are imported from these areas to Europe. Eastern Europe was initially isolated, but more recently provided spill-overs to Western Europe. Global phylogeographic trees show that European strains tend to cluster together, whereas North American strains are highly dispersed across the global genetic diversity. Sequences from North America also tend to have deeper roots than groups of sequences found in other regions, suggesting that North America has seeded the pandemic through multiple founder effect. Within Western Europe the United Kingdom was the most active in exchanging infections with non-European countries. As for mobility the most connected areas within Europe were found in the South. We also found that the degree of viral export from countries correlated with their number of subtype B infections. Major migrations can be connected to historical events.

Conclusions: The global spread of subtype B was not random. Viewing these patterns against the historical background, we observe that they strikingly mirror major geopolitical landmarks and trends since the end of World War II, namely the American influence over the Western World, the rise and fall of the Iron Curtain and major colonial relationships.

230 The 2 Phases of HIV-1 Group O Diversification

Marie Leoz[1]; Felix Feyertag[2]; Anfumbom Kfutwah[3]; Philippe Mauclere[4]; Guillaume Lachenal[5]; Florence Damond[6]; Veronique Lemee[1]; Francois Simon[7]; David Robertson[2]; Jean-Christophe Plantier[1]

[1]University Hospital Rouen, Rouen, France; [2]Manchester University, Manchester, United Kingdom; [3]Centre Pasteur du Cameroun, Yaounde, Cameroon; [4]Direction Interarmées du Service de Santé, Noumea, New Caledonia; [5]Université Paris Diderot, Paris, France; [6]APHP CHU Bichat Claude Bernard, Paris, France; [7]APHP CHU Saint Louis, Paris, France

Background: HIV-1 is subdivided into four groups: M, O, N and P. Group M is responsible for the pandemic, N and P are found in very few patients, and group O is endemic in Cameroon where it represents ~1% of HIV infections. Group O genetic diversity and evolution remain poorly characterised. Previous studies estimated its emergence to be as early as group M and have proposed different nomenclature systems. Here we fully investigate group O evolution, using an extensive dataset comprising sequences sampled from France, Cameroon and Gabon.

Methods: 190 HIV-O patients were sampled in France, Cameroon and Gabon between 1987 and 2012. Viral sequences from three regions of the genome were concatenated (total: 2012 base pairs) and analysed using phylogenetic and Bayesian population genetic methods to characterize evolutionary history.

Results: The tree topology was atypical, with a predominant clade emerging from a broad and genetically diverse base population. The presence of the Y181C mutation, naturally conferring resistance to non-nucleoside reverse transcriptase inhibitors, was significantly associated to the emergent clade.

The year of the most recent common ancestor (MRCA) was estimated to be around 1930, close to that of group M and consistent with previous estimates. Bayesian skyline analysis indicates group O diversification has gone through two exponential growth phases. The first phase, around 1950, resulted in widespread genetic diversity, while the second, from the late 1970s to the early 1990s, gave rise to the emergent clade.

According to the historical context in Cameroon, the first wave of group O expansion might have been favoured by iatrogenic routes of transmission between 1940 – 1960, while the second wave would rather be associated to the development of urbanization.

Conclusions: While groups O and M share a similar age, group O has remained largely confined to Cameroon. This has resulted in broad genetic diversity and intermixing of sub-populations, making it impossible to classify subtypes using a similar system as is used for group M. However, two subgroups can be observed corresponding to two successive phases of diversification. The viral properties of the two subgroups need to be investigated, to better understand why the now predominant clade was the most recent to emerge.

231 Evidence for More Major HIV-1M Lineages From the Early Stages of the HIV-1 Epidemic

Marcel Tongo Passo[1]; Wendy A. Burgers[2]; Eitel Mpoudi-Ngole[3]; Jeffrey Dorfman[1]; Darren P. Martin[4]

[1]International Center for Genetic Engineering and Biotechnology, Cape Town, Cape Town, South Africa; [2]Division of Medical Virology, University of Cape Town, Cape Town, South Africa; [3]Institute of Medical Research and Study of Medicinal Plants (IMPM), Yaoundé, Cameroon, Yaounde, Cameroon; [4]Computational Biology Group, University of Cape Town, Cape Town, South Africa

Background: One of the hallmarks of HIV-1 diversity is the occurrence of numerous mosaic circulating/unique recombinant forms (CRFs/URFs) which are not easily classifiable into any existing subtypes. There is, however, a lot of information stored within the genomes of these viruses which could be useful in efforts both to work out the early history of the HIV-1 pandemic, and to provide a better understanding on the origins and spread of different subtypes branching from near the roots of the HIV-1M phylogeny. Constantly improving phylogenetics-based analytical techniques and rapidly expanding HIV sequence datasets promise to yield important insights into how HIV first emerged.

Methods: In an effort to study the phylodynamics of the HIV-1M epidemic, we analysed a set of 577 genomic sequences including all published lineages from the Congo basin region and a selection of HIV lineages from the rest of the world designed to represent the full diversity of each subtype. A fully exploratory screen for recombination using RDP4 was performed with recombinant viruses being decomposed into their constituent parts. All sequences, including those belonging to "pure subtypes" were tested for recombination. Maximum likelihood phylogenetic analyses were used to identify rare parental sequences branching from near the root of the HIV-1M tree.

Results: Phylogenetic analyses of mostly recombination-free HIV-1M sequences indicated that many parental sequences of CRFs are not classifiable into the currently defined HIV-1M subtypes: Some of these parental lineages (including CRF02_AG, 04_cpx, 06_cpx and 11_cpx) contained more than 7000bp of unclassifiable sequence, suggesting that they are predominantly descended from what were/are major previously unidentified HIV-1M lineages that were likely epidemiologically relevant during the early stages of the HIV-1M epidemic. In addition, the phylogenetic tree also indicated that predominant parental sequences of some CRFs such as CRF47_BF and 05_DF were/are respectively highly divergent subgroup of B and D viruses. Furthermore, numerous sequences from the Congo basin branch basal to each subtype cluster, a finding consistent with this region being the geographic origin of the global HIV epidemic.

Conclusions: Our fully exploratory recombination screen suggests that many CRFs contain sequence fragments from previously unknown early diverging HIV-1 group M lineages. Such sequences could help tremendously with efforts to piece together the early evolutionary history of HIV-1M.

232 HIV-1/M+O Dual Infections and HIV-MO Recombinants in France From 2004 to 2014

Pierre Cappy[1]; Fabienne De Oliveira[1]; Veronique Lemee[1]; Jean-Louis Gaillard[2]; Laurence Bocquet[3]; Jean-Dominique Poveda[4]; Magali Bouvier[5]; Anne Maillard[6]; **Thomas Mourez**[1]; Jean-Christophe Plantier[1]

[1]Rouen University Hospital, Rouen, France; [2]Ambroise Paré Hospital, Paris, France; [3]Lille University Hospital, Lille, France; [4]CERBA Laboratory, Saint-Ouen L'Aumone, France; [5]Henri Mondor Hospital, Créteil, France; [6]Pontchaillou Hospital, Rennes, France

Background: Recombination is crucial for HIV evolution as pandemic HIV-M recombinants account for 20% of HIV-1 infections. HIV-M and -O co-circulation in Cameroon lead to dual infections and the subsequent generation of MO recombinants (MO). In France since 2004, one HIV-M/O superinfection, M+O dual infections and one MO have been described in patients linked to central Africa. In this study, we aimed to detect these forms in patients diagnosed in France with an HIV-O infection, and characterising the MO genomic patterns.

Methods: 141 samples from HIV-O infected patients were gathered from 2004 to 2014 by the French HIV-O Surveillance Network. M+O dual reactivities were screened for by gp120/V3 serotyping. On dually-reactive samples, group M and O specific PCRs were performed in *pol*, *acc* and *env* regions. Moreover, on HIV-O mono-reactive samples, M specific PCRs were also carried out when O amplification failed. Lastly, whole-genome sequencing was performed when possible, to characterise parental and recombinant strains.

Results: The presence of HIV-M and -O genomes was detected in 7% of patients (10/141). Two M+O dual infections were detected in 2 patients in 2004 and 2009. Two MO+O dual infections were detected on samples from 2005 and 2006 in epidemiologically linked patients and 1 MO+M+O triple infection in 2013. Finally 6 MO circulating alone were detected: 3 MO fully sequenced in 2008, 2010 and 2013 and 3 MO partially sequenced in 2010 (2 MO in one patient) and 2013. All the MO genetic patterns were different with breakpoints in the *acc* region (6/8), in LTRs (2/8) and $p17^{GAG}$ (1/8), *RT* (3/8), *INT* (2/8) and *gp41* (1/8) genes. The 2 viruses found in the same patient exhibited multiple breakpoints in *acc (2 and 5 respectively).*

Conclusions: Though all described in Cameroonian native patients, we showed HIV-M+O dual infections and MO recombinants circulate in France. Moreover, the presence of MO recombinants circulating alone and in epidemiologically linked patients demonstrate they are fit enough to be transmitted and spread. Finally, as HIV-O have still an impact on diagnosis and virological monitoring and are naturally resistant to non-nucleoside RT inhibitors, the transmission of HIV-M+O dual infections or MO recombinant forms carrying HIV-O genomic fragments underline the importance of searching for these forms, evaluate their spread dynamics and follow the possible emergence of a CRF_MO.

233 Evidence of Intra-Familial Transmission of an HIV-1 M/O Intergroup Recombinant Virus

Paul Alain T. Ngoupo[1]; Serge Alain Sadeuh-Mba[1]; Fabienne De Oliveira[2]; Valérie Ngono[1]; Laure Ngono[1]; Patrice Tchendjou[4]; Véronique Penlap Mbeng[3]; Richard Njouom[1]; Anfumbom Kfutwah[1]; Jean-Christophe Plantier[2]

[1]Centre Pasteur of Cameroon, Yaounde, Cameroon; [2]Virology, CHU Rouen, Rouen, France; [3]University of Yaounde I, Yaounde, Cameroon; [4]Epidemiology, Centre Pasteur of Cameroon, Yaounde, Cameroon

Background: HIV-1 groups M and O co-circulate in Cameroon and dual infections as well as HIV-1 M/O intergroup recombinant viruses have been reported in some patients. Recent data has described infection with HIV-1 M/O intergroup recombinant virus in the absence of dual infections thereby suggesting a direct transmission of the recombinant virus. In this study, we described and characterized an HIV-1 M/O intergroup recombinant virus in the absence of dual infection in a couple living in Cameroon. Here we provide for the first time evidence of a direct transmission of an HIV-1 M/O intergroup recombinant virus from one person to another.

Methods: Consecutive samples were obtained from a couple presenting for routine HIV viral load analysis. Prior to viral load analysis, each sample was subjected to HIV serotyping using envelope (V3 and gp41) peptides. These samples were subsequently screened for the presence of potential recombinant virus using specific PCRs targeting the Protease (PROT), Reverse transcriptase (RT), Integrase (INT) and envelope (gp41) genes of HIV-1 groups M and O. The previously reported recombination hotspot in the vpr gene was investigated using RT- nested PCRs. Near full length genome sequences of the viruses detected in both spouses were determined by amplification and sequencing of seven partially overlapping sub-genomic regions. Phylogenetic and similarity profile analyses were performed to investigate the genetic relatedness between viruses from both spouses.

Results: HIV serotyping indicated that samples from both patients (husband and wife) were reactive only with HIV-1 group O peptides thereby suggesting an infection with HIV-1 group O virus in both spouses. Molecular tests identified HIV-1 group M in the polymerase (PROT, RT and INT) and HIV-1 group O in the envelope (gp41) regions respectively. These results were consistent with phylogenetic analyses of corresponding sub-genomic regions. Altogether, phylogenetic analysis and similarity profile of the near full length genome sequences showed that both spouses were infected with a unique recombinant virus (M/O) having its recombination breakpoint in the vpr gene.

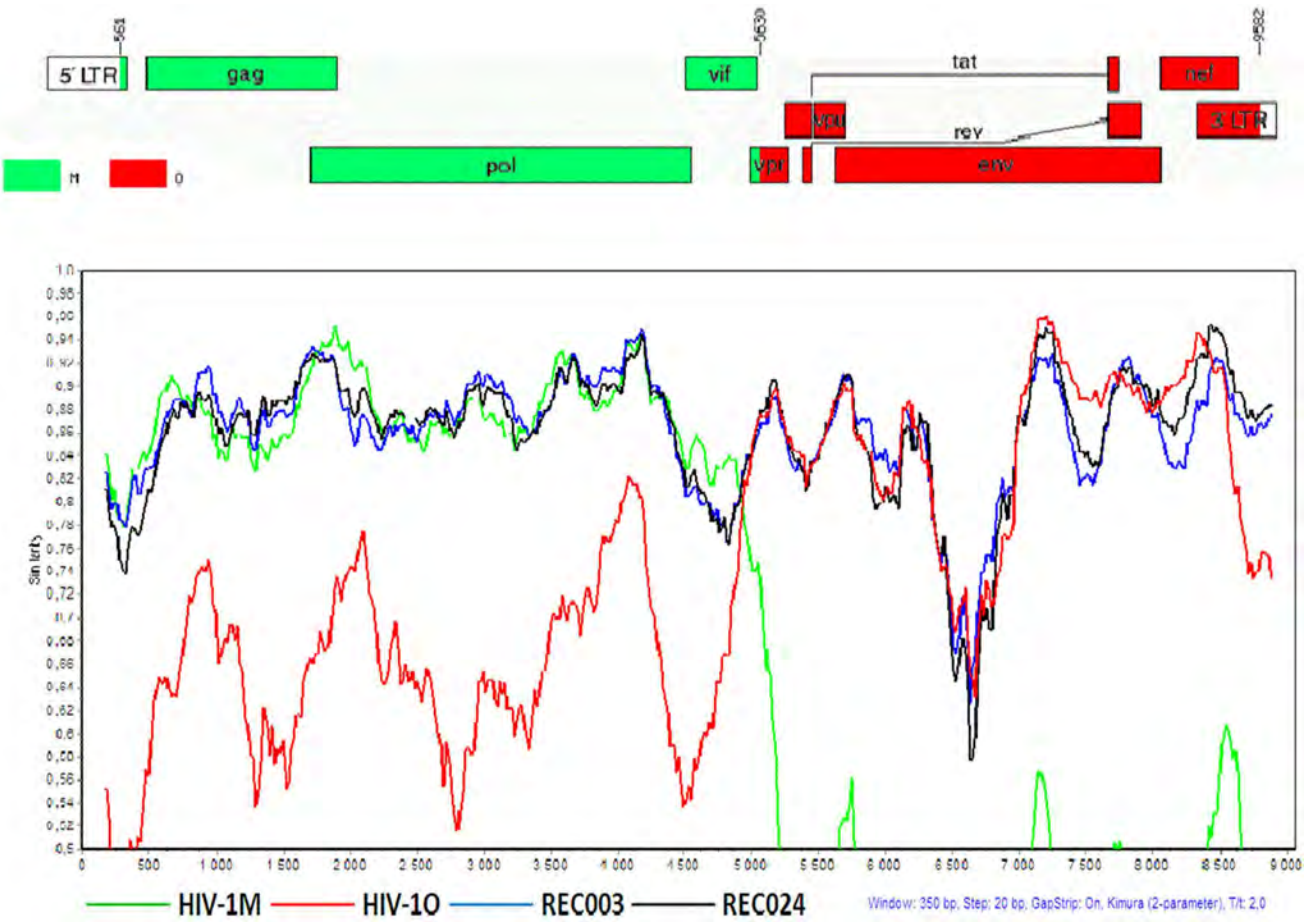

Figure 1: Recombination analyses of REC003 (Husband ; accession no KM438031) and REC024 (Wife; accession no KM438032) viruses

Near full-length genomes of REC003 (9135bp; blue line) and REC024 (9176bp; dark line) were compared each other and with the closest strains of HIV-1 group M (suptype F2; green line) and HIV-1 group O (red line) identified by HIV BLAST. The viruses exhibit a mosaic structure M-O with the gag-pol portion belonging to HIV-1 M and the env portion belonging to HIV-1 O. Both viruses defined the same patterns along the entire genome.

Conclusions: In this study, we observed for the first time that HIV-1 M/O intergroup recombinant viruses could be transmitted from one person to another. The genetic diversity and public health importance of transmitting these recombinant viruses in such areas where both viruses (HIV-1 groups M and O) are endemic cannot be overemphasized.

234 Searching for Rare HIV Strains in Rural Democratic Republic of Congo (2001–2003)

Ana S. Vallari[1]; Carole McArthur[2]; Larry Sthreshley[3]; Catherine Brennan[1]

[1]Abbott Laboratories, Chicago, IL, US; [2]University of Missouri–Kansas City, Kansas City, MO, US; [3]IMA World Health, Kinshasa, Congo (the Democratic Republic of the)

Background: The Democratic Republic of Congo (DRC) is thought to be the epicenter of the HIV/AIDs pandemic. Not only were the oldest documented HIV-1 infections found in Kinshasa (circa 1959-1960) but the many diverse HIV-1 strains circulating in the DRC show high levels of intrasubtype diversity and intersubtype recombination indicative of an old epidemic. In this study, we characterized HIV strains in two rural areas of the DRC to identify and obtain sequences for rare subtypes and recombinants found only in the DRC.

Methods: Specimens were collected, between 2001-2003, at the Vanga Hospital, Bandundu Province and The Good Shepard Hospital located 12 kilometers from Kananga, Kasia-Occidental Province in the DRC. A total of 264 HIV-infected specimens from voluntary testing and pregnant women participating in a PMTCT program were characterized. HIV serotype was determined based on antibody reactivity to HIV type and group specific peptides derived from *env* gp120 V3 loop and gp41 immunodominant region using a multiplex immunoassay. Strain classification was determined by RT-PCR amplification and phylogenetic analysis of the *env* gp41 sequence; for rare subtypes, *gag* and *pol* sequences were also obtained and evaluated.

Results: The peptide serotyping assay classified all infections as HIV-1 group M except for 2 HIV-2 infections. Phylogenetic analysis of 164 *env* sequences showed a high level of strain diversity. Subtype A predominated (43.9%) but 8 additional subtypes and 3 CRFs were found: subtype C (3.0%), D (9.8%), F1 (4.3%), G (12.2%), H (4.3%), J (1.2%), K (0.6%), L (0.6%), CRF01 (6.7%), CRF02 (8.5%), CRF11 (0.6%) plus unclassified (4.3%). Two subtype H, and the subtype J, K and L strains had concordant classification based on *gag*, *pol*, and *env* sequences.

Conclusions: Molecular characterization of HIV-infected specimens collected in the DRC show many different strains are circulating in the population and identified rare HIV subtypes H, J, K, and L for which very limited sequences are currently available. Subtype H, J and K sequences are most frequently found within CRFs thus the potentially pure subtype H, J, K and L strains identified here require confirmation by full genome sequencing. Continued surveillance of HIV strain diversity is important and essential to address the challenge posed by ongoing evolution of HIV and to monitor the rapidly changing HIV pandemic.

235 Clinical and Virological Characterization of CRF07_BC infection

Szu-Wei Huang[1]; Sheng-Fan Wang[1]; Chih-Hao Lee[1]; Wing-Wai Wong[2]; Hung-Chin Tsai[3]; Chia-Jui Yang[4]; Chin-Tien Wang[5]; Jaang-Jiun Wang[6]; Daniel Kuritzkes[7]; Yi-Ming A. Chen[1]

[1]Kaohsiung Medical University, Kaohsiung City, Taiwan; [2]Taipei Veterans' General Hospital, Taipei, Taiwan; [3]Kaohsiung Veterans' General Hospital, Kaohsiung City, Taiwan; [4]Far Eastern Memorial Hospital, New Taipei City, Taiwan; [5]National Yang-Ming University, Taipei, Taiwan; [6]Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, US; [7]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, US

Background: The circulating recombinant form (CRF) 07_BC is the most prevalent HIV-1 strain among injection drug users in Taiwan. It contains a 7 amino-acid deletion (7d) in its $p6^{gag}$. The objectives of this study were to conduct a cohort study to compare viral load and CD4 cell count changes between patients infected with subtype B and CRF07_BC and to elucidate its mechanism.

Methods: Twenty-one patients infected with CRF07_BC and 59 patients with subtype B were selected from a cohort of 667 HIV-1/AIDS patients whom have been followed up for more than 3 years. Generalized estimated equation was used for statistical analysis. The replicative kinetics, tropism and cytopathic effects were determined. HIV-1 NL4-3 which containing a 7 amino-acid deletion in $p6^{gag}$ (7d virus) was generated and its virological properties were compared with the wild-type.

Results: Patients infected with CRF07_BC had significantly lower viral load than patients with subtype B. CRF07_BC isolates had lower replicative capacity than subtype B isolates although they were all CCR5 tropic. 7d virus had significantly lower gag processing efficiency and slower viral life cycle. Electronic microscopy showed 7d virus had poorer viral maturation processes: virions attached to the cell membrane were largely immature. The interaction between $p6^{gag}$ and Alix protein was less efficient in cells infected with 7d virus.

Conclusions: Patients infected with CRF07_BC had significantly lower viral loads than patients infected with subtype B. Such phenomenon may be due to the deletion of 7 amino acids which overlap with the Alex protein-binding domain of CRF07_BC virus.

236 Reconstructing the HIV-1 Epidemics in Burkina Faso Using Early Samples

Gonzalo Yebra[1]; Marcia L. Kalish[2]; Andrew J. Leigh Brown[1]

[1]University of Edinburgh, Edinburgh, United Kingdom; [2]Vanderbilt University, Nashville, TN, US

Background: Two HIV-1 recombinants dominate the epidemics in Burkina Faso: CRF06_cpx (first described in this country) and CRF02_AG. Here, we reconstruct the phylodynamics of both epidemics in Burkina Faso and Western Africa using for the first time early sequences from samples taken in 1986 and modern sequences from GenBank.

Methods: The early sequences were 52 protease (PR) and 37 gp41 sequences for CRF06_cpx and 15 PR and 25 gp41 for CRF02_AG; to which we added GenBank sequences (1993-2013). For CRF06_cpx, we analysed all sequences (163 PR / 41 gp41). For CRF02_AG, we analysed Burkina Faso sequences (142 / 39) and, in a second analysis, sequences from Western Africa (380 / 170) and the closest sequences from Central Africa (311 / 128). Owing to the short length of the sequences available, we analysed sequence data for both genes jointly using the BEAST multilocus analysis to improve convergence and confidence intervals on the growth curves. We also conducted a phylogeographic analysis by using the discrete traits analysis implemented in BEAST to reconstruct the main migration routes between countries.

Results: The most recent common ancestor (MRCA) of global CRF06_cpx was 1979 (1977-1980) for both PR and gp41, with respective evolutionary rates of 5.5 (4.8-6.3) $\times 10^{-3}$ substitutions/site/year (s/s/y) and 6.1 (4.8-7.5) $\times 10^{-3}$ s/s/y. The phylogeographic analysis of gp41 showed that CRF06_cpx (or at least its parental subtype G lineage) emerged in the Democratic Republic of Congo (DRC) but arrived soon after (1981) in Burkina Faso. Both PR and gp41 showed that this recombinant radiated to the rest of Western Africa only around 1990. The MRCA of CRF02_AG in Burkina Faso was 1979 (1977-81) for both PR and gp41 with rates of 2.3 (1.8-2.9) $\times 10^{-3}$ s/s/y and 5.7 (4.1-7.4) $\times 10^{-3}$ s/s/y. In West Africa, the phylogenetic trees showed CRF02_AG sequences interspersed regardless of their sampling country, and the phylogeographic analysis showed much interconnection between countries with 3 main transmission hubs in Cameroon, Burkina Faso and Senegal.

Conclusions: Burkina Faso presents a relatively young HIV epidemic, with the two main variants originating around 1980. CRF06_cpx might have emerged in DRC but radiated throughout Western Africa from Burkina Faso. However, CRF02_AG entered Burkina Faso though multiple introductions. Indeed, the CRF02_AG epidemic showed much interchange between Western African countries but also connections with Central Africa, which suggests a great mobility in the region.

237 Neutralizing Antibodies in Humans Infected With Zoonotic Simian Foamy Viruses

Caroline Lambert[1]; Julie Gouzil[2]; Réjane Rua[1]; Edouard Betsem[3]; Antoine Gessain[1]; **Florence Buseyne**[1]

[1]Institut Pasteur, Paris, France; [2]Ecole Vétérinaire, Maison-Alfort, France; [3]University of Yaounde, Yaounde, Cameroon

Background: Simian foamy viruses (SFVs) are efficiently transmitted from non-human primates to humans, establishing persistent infection in the new host. Neither pathogenic effects nor human-to-human transmission have been reported, suggesting that immune control of this retrovirus is efficient. Here, we aimed at studying the humoral response. We used viral strains isolated from animals and infected humans to study the neutralizing antibodies present in the plasma of SFV-infected people living in rural areas of South Cameroon.

Methods: Serial dilutions of plasma samples from 46 SFV-infected individuals and seven uninfected subjects were incubated with SFV. Residual viral infectivity was quantified with an indicator cell line expressing the beta-galactosidase gene under the control of the LTR from the prototypic strain, SFVcpzPFV. Four strains from the chimpanzee clade were used: the SFVcpzPFV and SFVcpzSFV7 strains, from serogroups 6 and 7, respectively, and the SFVcpzBAD327 and SFVcpzAG15 strains, isolated from individuals from our study population.

Results: Plasma samples from the six people infected with SFV from the chimpanzee clade neutralized either SFVcpzPFV or SFVcpzSFV7. Plasma samples from the seven uninfected individuals and the five individuals infected with SFV from small monkeys did not neutralize any SFVcpz strain. In total, 35 people were infected with SFV from the gorilla clade: 21 of these plasma samples neutralized the SFVcpzPFV strain, eight neutralized the SFVcpzSFV7 strain and one neutralized both strains. Neutralizing titers ranged from 1/30 to 1/2060. Five plasma samples did not neutralize any of the strains tested. The titers of neutralizing antibodies against the zoonotic SFVcpzBAD327 and SFVcpzAG15 strains were strongly correlated with the titers of neutralizing antibodies against the SFVcpzSFV7 strain (Spearman's rho=0.998, $P<0.0001$ and rho=0.957 $P<0.0001$, respectively).

Conclusions: SFVs from the chimpanzee and gorilla clades transmitted to humans had similar antigenic properties and belonged to at least two serogroups described in non-human primates. The conservation of the neutralizing epitopes may account for the efficient immune control of these retroviruses. No SFV RNA was detected in the peripheral blood and saliva of these individuals, but the relatively high titers of neutralizing antibodies in some of them suggest that active SFV replication may occur in humans with persistent zoonotic SFV infections.

Defining Epidemiologically Linked Transmission

238 Large Phylogenetically Linked HIV Cluster in King County, Washington, 2008 to 2014

Susan E. Buskin[1]; Joshua T. Herbeck[2]; Katelynne M. Gardner Toren[1]; Michelle R. Perry[1]; Amy Bennett[1]; Matthew R. Golden[2]

[1]*Public Health—Seattle & King County, Seattle, WA, US;* [2]*University of Washington, Seattle, WA, US*

Background: Core transmission is a basic tenant of sexually transmitted infection (STI) epidemiology—that a few individuals are responsible for a large proportion of STI transmissions. However, relatively little data exist on core transmission for HIV. We present phylogenetic analyses supporting the role of a core transmitter of HIV infection.

Methods: Public Health – Seattle & King County (PH) field services staff identified an individual (index case) diagnosed with HIV infection in 2008 and who was named as a potential transmitting sex partner by 11 different men between 2008 and 2014. We used PH HIV-1 *pol* nucleotide sequences collected by Molecular HIV Surveillance for HIV cases diagnosed 1/08 to 9/14 to assess the phylogenetic relatedness of people naming the index case as a sex partner, and to define the size of the associated transmission cluster.

Results: Phylogenetic data were available for 10 of 12 men identified through field services investigations. Seven of the 10 epidemiologically-linked cases were phylogenetically linked in a cluster of 66 cases; this was the largest subtype B cluster identified in the area, comprising 5% of 1430 sequences analyzed over the period of observation. Of the 66 cluster cases, 7 including the index case were diagnosed in 2008, 5 in 2013, and 3 (to-date) in 2014; the modal year was 2012 with 17 diagnoses. All but 1 case was male, and 94% reported sex with men. All 66 cluster cases had primary high-level non-nucleoside reverse transcriptase (NNRTI) resistance; these 66 are 36% of all NNRTI resistant cases in the time period. Sequences from the 66 cluster cases were collected 0 to 485 days from HIV diagnosis (median 16 days); none had achieved viral suppression prior to specimen collection. A most recent viral load was suppressed (< 200 copies per ml) for 54 individuals (82%). Of the remaining 12 individuals, 5 had > 1 log reduction in viral load (range 1.6 to 3.8), one individual relocated, and the remaining 6 are under investigation but are not known to be virologically suppressed. The index case was not previously virally suppressed, but was successfully relinked to care by PH.

Conclusions: This large cluster of epidemiologically and molecularly-related cases supports the role of core transmission in HIV infection. The ability of field services staff to identify an untreated man who we believe played a central role in this transmission network demonstrates the utility of routine partner services investigations.

239 Reconciling Named Partner and Genetic Partner HIV-1 Transmission Networks in New York City

Joel O. Wertheim[1]; Sergei L. Kosakovsky Pond[1]; Konrad Scheffler[1]; Davey M. Smith[1]; Sanjay Mehta[1]; Sharmila Shah[2]; Lisa Forgione[2]; Lucia V. Torian[2]

[1]*University of California San Diego, San Diego, CA, US;* [2]*New York City Department of Health and Mental Hygiene, New York, NY, US*

Background: The New York City Department of Health and Mental Hygiene (DOH) interviews persons with newly diagnosed HIV infection (index cases) and elicits partners, who are notified of exposure and offered HIV testing. When resistance testing is ordered by a physician with whom the case or positive partner has initiated care, the viral nucleotide sequence is reported to surveillance.

Methods: Between 2006 and 2012, DOH interviewed 770 index cases with genotypes; these cases named 810 HIV+ partners with genotypes, for a total of 1,369 cases linked to named partners (211 index cases were also named by other index cases). Using *pol* sequences, we identified index and named partners who were closest relatives in a maximum likelihood phylogeny. We then estimated the Tamura-Nei 93 (TN93) genetic distance between each pair of index cases and named partners. We designated viral sequence pairs that fell below a validated distance cutoff of 1.75% as genetic links. Our data made it possible to construct two networks: the network of cases and their named partners (the named partner network; N=1,369) and the network of clusters of persons genetically linked by their TN93 distance (the genetic partner network; N=862 [63% of the 1369 cases]). We examined the degree of overlap between the two networks. We used logistic regression to assess the variables associated with the index case successfully naming at least one genetically linked partner.

Results: 451 of 770 (59%) index cases named partners who were also genetically linked (Table). Heterosexual female index cases were more likely to be genetically linked to a named partner (77%) than men who have sex with men (42%, OR=0.21, 95% CI 0.14, 0.31) and male injecting drug users (38%, OR=0.18, 95% CI 0.08, 0.38). Black index cases were less likely than whites and Hispanics to name a genetically linked partner (53%, OR=0.46, 95% CI 0.25, 0.87). In the named partner network, 747 out of 1,369 (55%) cases were genetically linked to a named partner, whereas in the genetic network, 720 out of 862 (84%) persons were genetically linked to a named partner.

Logistic regression analysis of FSU index partner being genetically-linked to at least one of their named partners (n = 770 index partners).

Demographic	Category[1]	Total	Named ≥ 1 genetically linked partner	Did not name a genetically linked partner	% with genetically linked partner	Odds Ratio[2]	95% confidence interval	p-value
Total	-	770	451	319	-	-	-	-
Risk	Hetero (F)	218	167	51	77%	1	-	-
	Hetero (M)	93	72	21	77%	1.14	0.62–2.07	0.677
	MSM	343	143	200	42%	0.21	0.14–0.31	>0.001
	IDU (F)	15	8	7	53%	0.38	0.13–1.13	0.083
	IDU (M)	39	15	24	38%	0.18	0.08–0.38	>0.001
	Other/Unknown	62	46	16	74%	1.04	0.54–2.03	0.904
Race[3]	White	55	32	23	58%	1	-	-
	Black	398	211	187	53%	0.46	0.25–0.87	0.016
	Hispanic	311	208	103	67%	0.92	0.48–1.78	0.810

Hetero, heterosexual; MSM, men who have sex with men; IDU, injecting drug user

[1]Demographic categories reflect index case partner only.
[2]Model adjusted odds ratio. Variables not significantly associated with linking (i.e. country of birth, subtype, diagnosis status, AIDS status, and age) are not shown.
[3]Only whites, blacks, and Hispanics had sufficient numbers for display

Conclusions: Construction of genetic transmission networks can supplement partner naming by identifying previously unknown parts of a potential transmission network, i.e., unnamed partners. If real-time genotyping coupled with network analysis can be implemented, it can be used to interdict ongoing transmission and to improve epidemic control.

240 Efforts to Characterize Community HIV Transmission Dynamics May Be Critically Dependent on Provision of Both Partner Services and Genetic Sequence Analysis

Nella L. Green; Christy Anderson; Sergei L. Kosakovsky Pond; Martin Hoenigl; David M. Smith; Sanjay Mehta; Susan Little

University of California San Diego, San Diego, CA, US

Background: Genetic analysis of HIV-1 sequences has become the gold standard for inferring HIV transmission networks. However, the added value of epidemiological links supplied via partner counseling and referral services (PCRS) is unclear.

Methods: We examined bulk *pol* sequence and epidemiological data from the San Diego Primary Infection Resource Consortium (PIRC) collected between 1996 and 2013. PCRS services were routinely provided to recently HIV infected persons to characterize epidemiologically linked partnerships (named partners). Two individuals whose nucleotide HIV-1 sequences differed by at most 1.5% (Tamura-Nei 93 distance) were considered genetically linked. We compared two types of putative transmission pairs: Group 1: genetically and epidemiologically linked, and Group 2: genetically, but not epidemiologically linked.

Results: 591 newly HIV infected persons were identified in the PIRC cohort. Provision of PCRS yielded 184 epidemiologically linked partnerships, of which 52 (28%) were also genetically linked (Group 1). Of the remaining 132 partnerships, 93 were linked to HIV-negative individuals and 39 (21% of total) were linked to HIV-infected persons whose genetic sequences differed. Sequence analysis alone identified 459 dyads (i.e. Group 2). 337 individuals made up the 511 pairs (Groups 1 + 2) included in this analysis. There were no significant differences comparing dyad concordance between Groups 1 and 2 with regard to race, ethnicity, income, CD4, viral load, and recent or current sexually transmitted infections. Partner age differences were greater in Group 2 ($p = 0.012$). The elapsed time between identification of the index and their linked partner was significantly different ($p<0.001$) between groups (Group 1 median 15 days [IQR 7-46 days]; Group 2 median 532.5 days [IQR 222-1194 days]).

Conclusions: Sequence analysis and PCRS may identify a uniquely different population than that identified with sequence analysis alone. As expected, only a minority (28%) of PCRS pairs were corroborated by genetic data, yet these partnerships yielded a more rapid linkage identification (15 days vs 532 days) and also captured individuals more similar in age, as compared to partnerships identified solely by genetic analysis. We conclude that the primary and valuable benefit of PCRS is to yield recently connected putative transmission pairs that may represent more attractive targets for interventions and are more likely to represent direct transmission events.

2:30 pm – 4:00 pm

Transmission Clusters

241 Growth and Geographic Spread of HIV Transmission Clusters, United States, 2007-2012

Alexandra M. Oster[1]; Joel Wertheim[2]; Ellsworth Campbell[1]; Angela L. Hernandez[1]; Neeraja Saduvala[2]; William M. Switzer[1]; M. Cheryl Ocfemia[1]; Anupama Shankar[1]; H. Irene Hall[1]

[1]US Centers for Disease Control and Prevention (CDC), Decatur, GA, US; [2]ICF International, Atlanta, GA, US

Background: Molecular epidemiology can be used to identify clusters of persons with genetically related viruses. Clusters that continue to grow over time likely represent ongoing transmission and are potential points for intervention. Predicting which clusters are likely to grow could guide the appropriate allocation of limited prevention resources toward ensuring viral suppression and stemming transmission.

Methods: We aligned HIV-1 sequences (1/person) reported to the U.S. National HIV Surveillance System to a reference sequence, conducted pairwise comparison of 70,669 sequences, and constructed an HIV transmission network of sequences with Tamura-Nei genetic distance ≤1.5%. We used HIV diagnosis year to construct the network over time and assess changes during 2007–2012. For clusters with ≥5 persons in 2007, we characterized growth through 2012 and used multivariable logistic regression to examine potential predictors of various levels of growth, including cluster size in 2007, cluster growth from 2006 to 2007, and demographic/risk characteristics. Finally, we described geographic characteristics of the largest clusters.

Results: From 2007 to 2012, the number of persons with sequences and the number of clusters grew substantially (Table). In 2007, 177 clusters contained ≥5 persons. By 2012, these 177 clusters grew 235% overall, from 1,492 to 3,500 persons. Twenty-nine (16%) clusters grew ≥200% during 2007–2012, representing 54% of growth among clusters of ≥5 persons. Clusters that grew ≥200% did not differ from clusters that grew <200% with respect to size in 2007, growth from 2006 to 2007, racial/ethnic makeup, or the percentage of men who have sex with men (MSM). However, higher percentage of persons aged 13–19 years was associated with growth ≥200% ($p=0.048$). Growth ≥100% (n=76 clusters) was associated with rate of cluster growth from 2006 to 2007 ($p=0.01$) and higher percentage of MSM ($p=0.04$). Of the 8 largest clusters (size=79–155 in 2012), 5 consisted nearly exclusively (>90%) of persons living in the same state at diagnosis, one included persons from 7 Southern states, and two included persons from across the United States.

	2007	2012
No. of persons with sequences	36,947	70,669
No. (%) of persons who clustered	4,667 (13%)	21,117 (30%)
Number of clusters	1,520	5,336
Size of largest cluster	65	155

Characteristics of HIV transmission clusters, 2007 and 2012

Conclusions: We found substantial growth of clusters over a 5-year period. The best predictors of cluster growth ≥100% were growth in the previous year and the percentage of MSM. Rapid growth (≥200%) was best predicted by the percentage of adolescents. These data suggest that monitoring the growth and composition of clusters can help to identify prevention priorities.

242 HIV Transmission Networks Among the USA, Mexico, and Central America

Santiago Avila-Rios[1]; Joel O. Wertheim[2]; Ann M. Dennis[8]; Gustavo Reyes-Terán[1]; Carlos Mejía-Villatoro[3]; Elsa Y. Palou[4]; Guillermo Porras-Cortes[6]; Juan M Pascale[5]; Marvin Manzanero[7]; Sanjay Mehta[2]

[1]National Institute of Respiratory Diseases, Mexico City, Mexico; [2]University of California San Diego (UCSD), San Diego, CA, US; [3]Roosevelt Hospital, Guatemala City, Guatemala; [4]Hospital Escuela Universitario, Tegucigalpa, Honduras; [5]Gorgas Memorial Institute for Health Studies, Panama, Panama; [6]Vivian Pellas Metropolitan Hospital, Managua, Nicaragua; [7]Ministry of Health, Belmopan, Belize; [8]University of North Carolina, Chapel Hill, NC, US

Background: The role of migration in shaping genetic diversity of viral populations has been well established. We show results of a large collaborative effort to assess epidemiological networks and dispersion routes between the HIV epidemics in the United States, Mexico and Central America, including Guatemala, Belize, Honduras, El Salvador, Nicaragua and Panama.

Methods: We analyzed 7943 HIV-1 *pol* sequences collected from Mexican and Central American national HIV sequence databases, and local databases located at the University of North Carolina and the University of California, San Diego. These sequences were aligned to the reference sequence HXB2. We then estimated Tamura-Nei (TN) 93 pairwise genetic distances among all sequences. Sequences that were ≤1.5% TN93 distance divergent were deemed similar enough to be potential transmission partners. We then constructed transmission clusters by linking sequences through shared potential transmission partners.

Results: In total, 2349 (30%) of sequences had a potential transmission partner in the network, comprising 846 distinct transmission clusters (range 2-53 members). Twenty five (3.0%) of these clusters included sequences isolated from at least two individuals in different countries, and six clusters included sequences isolated from both San Diego and North Carolina. Fourteen clusters included linkages between sequences isolated in San Diego and in Mexico. North Carolina sequences were linked to sequences from Guatemala in three clusters, Panama in two clusters and Mexico in two clusters; nearly all these sequences were from Latino immigrants. Below is a figure depicting all of the clusters identified in this analysis with nodes shaded by country of origin.

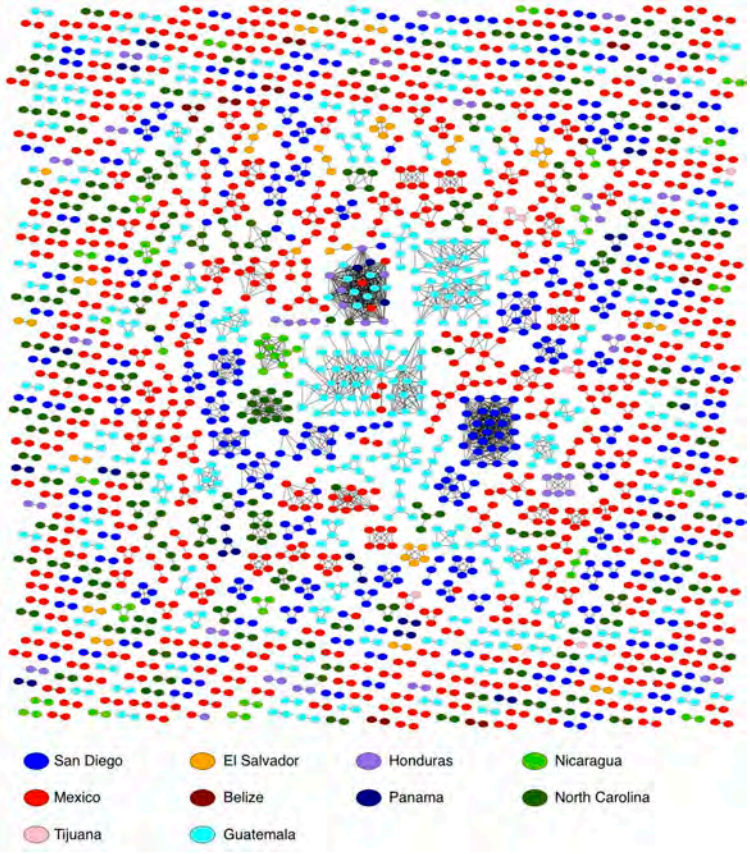

Figure 1. HIV transmission clusters in the USA, Mexico and Central America. Tamura-Nei 93 pairwise genetic distances were estimeted among 7943 pol sequences and clusters were constructed by linking sequences through shared potential transmission partners. Only sequences forming clusters are shown. Each node represents a single sequence colored by geographic region.

Conclusions: Our work underlines the importance of political and cultural barriers in HIV transmission among the USA, Mexico and Central America, with most transmission events occurring within countries. Nevertheless, the presence of some international connections was observed, reflecting possible important events influencing HIV diversity in the region. Continued network analyses have the potential to inform transnational HIV prevention efforts.

243 Sexual Networks Across Risk Groups Persistently Contribute to Local Spread of HIV

Marije Hofstra[1]; Tania Mudrikova[1]; Marieke Pingen[1]; Kristine Koekkoek[1]; Arjan Van Laarhoven[1]; Rob Schuurman[1]; Andy I. Hoepelman[1]; Annemarie M. Wensing[1]

[1]University Medical Center Utrecht, Utrecht, Netherlands; [2]University Medical Center Utrecht, Utrecht, Netherlands

Background: Despite the sharp drop in influx of immigrants from HIV endemic countries since 2003, HIV incidence is not decreasing in the Netherlands. This could be due to increased testing and/or increased incidence among the native Dutch population. Therefore we aimed to get insight in local transmission dynamics.

Methods: In 2004-2013, 709 adults newly diagnosed with HIV presenting at the University Medical Center Utrecht participated in the local Athena cohort. *Pol* sequences of 663 (94%) therapy-naive patients were aligned with 212 *pol* sequences of therapy-experienced patients from the same period. A neighbor-joining phylogenetic tree was constructed (evolutionary model Tamura-Nei, 1000 replicates, MEGA6). Transmission clusters were identified using a threshold of bootstrap support of 95% and genetic distance <0.015. Subtyping was performed using COMET v0.5.

Results: Of all newly diagnosed patients, the majority (84.9%) was male with a mean age of 39 years. MSM was the main route of transmission (65.6%), followed by heterosexual contact (HSX; 27.2%) and IV drug use (0.8%). The majority was of Dutch ancestry (73.9%), 11.6% was originating from sub Saharan Africa and 14.5% from other regions. Half of the newly diagnosed patients (53.4%) were part of a transmission cluster. We identified 19 large clusters (6-23 patients, n=193): 1 subtype C cluster of 18 patients of Dutch origin (11 MSM, 2 female HSX, 3 male HSX, 2 unknown), 1 subtype A1 cluster of 8 patients of Dutch origin (5 MSM, 1 male HSX, 2 female HSX) and 1 subtype CRF02_AG cluster of 6 MSM patients of mixed origin. The other 16 large clusters were all subtype B, of which 11 clusters consisted only of patients of Dutch ancestry. Six clusters included both MSM and male HSX and 1 cluster MSM and female HSX. Using prior negative HIV test results, the mean persistence of these clusters was at least 48 months, with a range from 10 to 82 months. The non-B subtypes have been circulating for at least 33 (CRF02_AG), 36 (A1) and 75 (C) months.

Conclusions: Half of the newly diagnosed HIV patients were part of a local cluster that persisted for up to nearly 7 years, suggesting local transmission highly contributes to the HIV epidemic in the area. Longstanding clusters of non-B subtypes are seen in patients of Dutch origin transcending different risk groups.

244 Estimation of HIV-1 Transmission During Recent Infection in Switzerland

Alex Marzel[1]; Mohaned Shilaih[1]; Wan-Lin Yang[1]; Jürg Böni[2]; Sabine Yerly[3]; Thomas Klimkait[4]; Vincent Aubert[5]; Huldrych F. Günthard[1]; Roger Kouyos[1]
On behalf of the Swiss HIV Cohort Study (SHCS)

[1]Division of Infectious Diseases and Hospital Epidemiology, University Hospital Zurich, Zurich, Switzerland; [2]Swiss National Center for Retroviruses, Zurich, Switzerland; [3]Laboratory of Virology, Geneva, Switzerland; [4]Department of Biomedicine–Petersplatz, Basel, Switzerland; [5]Division of Immunology and Allergy, Lausanne, Switzerland; [6]The Swiss HIV Cohort Study, Zurich, Switzerland

Background: Knowing the fraction of transmissions attributable to recent HIV infections is essential for the success of Treatment-as-Prevention. This is because recently infected patients are often unaware of their HIV status and hence remain untreated and highly infectious.

Methods: A maximum-likelihood phylogeny was constructed from 121,306 HIV-1 pol sequences (21,471 sequences from 11,567 Swiss HIV Cohort Study (SHCS) participants and 99,835 sequences from the Los Alamos database). Swiss transmission clusters were identified using different combinations of intra-cluster genetic distance (1%, 1.5%, 2%, 2.5%) and bootstrap (50% to 100% by increment of 2%) thresholds, in order to determine the effect of those criteria. Seroconversion dates were estimated based on immunological markers, dates of HIV positive/negative tests, clinical symptoms and ambiguous nucleotides. Transmission clusters were classified as recent or chronic transmission based on the maximal time interval between the seroconversion dates of the cluster members. Logistic regression with adjustment for age, sex, risk group, HIV subtype, baseline RNA/CD4, time-to-ART and Chronic phase RNA viral load integral, was applied to identify, among transmitters, the risk factors associated with having transmitted in the recent or chronic phase.

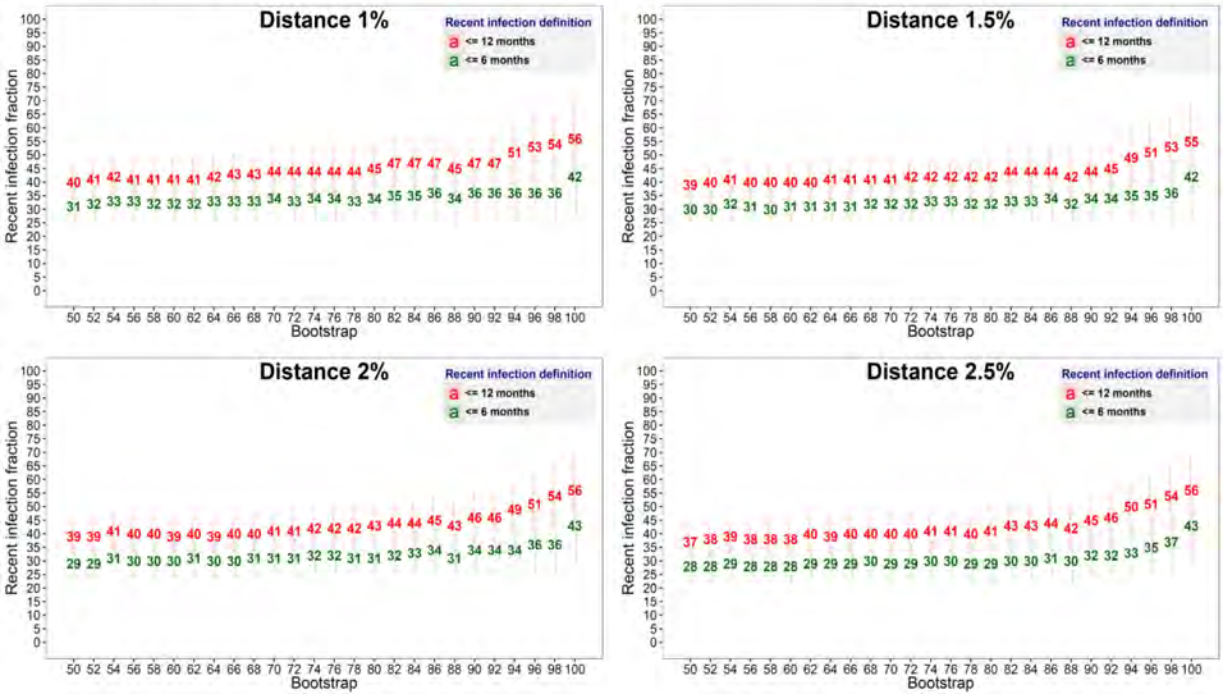
Results: Depending on the implemented phylogenetic threshold criteria, we identified between 50 to 271 transmission clusters with known seroconversion dates for all members. These clusters showed that:

1. The median fraction of transmission during recent infection was 42.2% (range 37%-56%) when recent infection was defined as the first year of the infection and 32% (range 28%-43%) for a six months definition.

2. Stricter criteria for defining transmission cluster (higher bootstrap thresholds) were strongly associated with higher fractions of recent phase transmission, Figure 1, (Spearman`s rho 0.95, P <0.001).

3. The total viral load in the chronic phase (measured as the Chronic phase RNA viral load integral) was negatively associated with recent as opposed to chronic phase transmission, OR 0.43 (0.24-0.77). This effect was even stronger in the adjusted model OR 0.25 (0.1-0.67).

Figure 1. Estimation of HIV-1 transmission during recent infection in the SHCS, by varying phylogenetic thresholds for a definition of transmission cluster. Numbers in red represent recent transmission fraction according to a definition of twelve months for recent infection. Numbers in green represent recent transmission fraction according to a definition of six months for recent infection. Vertical lines represent 95% confidence intervals for proportion.



Conclusions: Our data points to a high fraction of transmission during recent HIV infections in the SHCS. Moreover, we show that the total viral load in the chronic phase is a strong determinant of the transmission phase. These results are important to the pertinent debate on Treatment-as-Prevention as an "Endgame" strategy.

245 Clustering of Swiss HIV Patients Not Enrolled in the Swiss HIV Cohort Study (SHCS)

Mohaned Shilaih[1]; Alex Marzel[1]; Jörg Schüpbach[1]; Jürg Böni[1]; Sabine Yerly[2]; Thomas Klimkait[4]; Vincent Aubert[3]; Huldrych F. Günthard[1]; Roger Kouyos[1]
The Swiss HIV Cohort Study (SHCS)

[1]University Hospital Zurich, Zurich, Switzerland; [2]Geneva University Hospital, Geneva, Switzerland; [3]University Hospital Lausanne, Lausanne, Switzerland; [4]University of Basel, Basel, Switzerland; [5]University of Zurich, Zurich, Switzerland

Background: One of the central challenges in HIV surveillance is that the surveyed population might not be representative of the entire HIV-infected population, especially with respect to marginalized populations. The SHCS is exceptionally representative (75% of HIV patients on ART), however the possibility remains that entire sub-epidemics might be missed by the cohort. A unique opportunity to assess the presence of such "under the radar" populations is provided by a database of all genotypic resistance tests performed in Switzerland, which includes both cohort and non-cohort patients.

Methods: Phylogenetic cluster analysis was used to assess the presence of a hidden sub-epidemic. 11338 SHCS and 3099 Swiss non-SHCS sequences were pooled with 27803 background sequences from the Los Alamos database (10 best BLAST hits for each Swiss sequence). A maximum likelihood phylogenetic tree was built using FastTree. Clusters that were dominated by Swiss sequences (>=80%) were interpreted as Swiss transmission clusters.

Results: Non-B subtypes were strongly overrepresented in the non-SHCS compared to the SHCS (OR 3.0, 95%CI 2.8-3.3). Moreover, non-SHCS patients were more likely to be female (OR 1.4, 95%CI 1.3-1.6). Transmission groups were assigned to non-cohort sequences based on phylogenetic proximity. This revealed that heterosexuals were more present among non-SHCS patients (OR 2.0, 95%CI 1.8-2.2; compared to MSM). Associations remained significant after adjusting for sex, test date, and subtype.

We found 301 transmission clusters purely of non-SHCS patients. However, these clusters were small (median 4.5, IQR 3.25-5.75, max 9) compared to those consisting only of SHCS patients (median 7.5, IQR 4.75-10.2, max 17). Non-SHCS patients were more likely to be part of a transmission cluster compared to SHCS patients (OR 1.9, 95% CI 1.8-2.1). However, when sample date was included in the logistic regression model said clustering preference of non-SHCS markedly decreased (1.1, 95%CI 0.99-1.2).

Conclusions: In this work we evaluated the coverage of the SHCS, one of the most representative HIV cohorts. We found an overrepresentation of non-B subtypes among non-SHCS patients suggesting that migrants might be underrepresented in the SHCS. We also observed transmission chains among non-SHCS patients, yet their limited size and frequency suggest that no major HIV outbreak in Switzerland is missed by the SHCS. More generally, this work shows the potential of sequence data to assess the representativeness of cohort studies.

246 HIV Transmission Network Structure Reveals Characteristics of Bridging Individuals

Sanjay Mehta; Joel O. Wertheim; Konrad Scheffler; Susan Little; Richard R. Garfein; Sergei L. Kosakovsky Pond; David M. Smith

University of California San Diego, La Jolla, CA, US

Background: Molecular epidemiology is often the only means to reveal difficult-to-measure patterns of HIV transmission in local epidemics. Of particular interest are "bridge" individuals that link otherwise disconnected network components, evaluated here for the inferred San Diego Primary Infection Cohort (SDPIC) HIV transmission network.

Methods: We inferred a molecular transmission network (MTN) from a curated collection of 1024 partial *pol* sequences, representing 713 SDPIC participants sampled between 1996 and 2013, and 311 sequences from area chronically infected individuals. Two individuals (nodes) were linked if their sequences were <1.5% distant (TN93 metric). Network degree, mean path length (MPL), and betweenness centrality were computed for each network node, and statistical analyses were used to examine which sociodemographic factors associated with network properties. We also investigated the association of a novel "uniqueness" score with the various measures of network centrality. This score combined the demographic attributes of age, race, ethnicity, HIV risk factor, and location of residence into a single score, which was then used to compare all of the individuals within each transmission cluster relative to one another.

Results: 42.1% of individuals in our study were linked to at least one other individual in the MTN. Age of individuals was the only sociodemographic measure marginally associated with centrality in univariate analyses [p=0.053, age vs clustering, t-test]. In clusters comprising 4 or more individuals, central nodes (low MPL) were significantly more likely [p=0.05, Fishers Exact Test] to have higher uniqueness scores, and the highest scoring individuals had significantly higher betweenness centrality [25.6% vs 8.2%, p=0.041, t-test].

Conclusions: In models of epidemiologic spread, individuals who serve as bridges between otherwise disconnected groups have been implicated as important drivers of HIV epidemics. Our analyses demonstrate in the San Diego HIV epidemic, bridging individuals were sociodemographically unique. Such uniqueness represents a higher degree of disassortative mixing by these key individuals, suggesting that disassortative partnerships may disproportionately drive HIV epidemics.

247 Phylodynamic Analysis of HIV Sub-Epidemics in Mochudi, Botswana

Vladimir Novitsky[1]; Denise Kuehnert[2]; Sikhulile Moyo[3]; Erik van Widenfeldt[3]; Lillian Oku[3]; Max Essex[1]

[1]Harvard School of Public Health, Boston, MA, US; [2]ETH Zürich, Zürich, Switzerland; [3]Botswana-Harvard AIDS Institute Partnership, Gaborone, Botswana

Background: The rapid intrinsic evolution of HIV-1 makes it possible to infer epidemiologic patterns from sequence data. The Bayesian birth-death skyline (BDSKY) plot was introduced recently as a model of virus transmission. We used BDSKY to estimate the effective reproductive number, *R*, and the timing of virus transmission, to distinguish "acute" HIV sub-epidemics (*with* recent viral transmissions) from "historic" sub-epidemics (*without* recent viral transmissions) in a southern-African community.

Methods: Study subjects participated in enhanced household-based HIV Testing and Counselling in Mochudi, a peri-urban village in Botswana. The sampling density was around 70%. HIV-1C V1C5 sequences were generated for 1,248 residents of Mochudi. HIV-1C sub-epidemics were identified by a combination of bootstrapped maximum likelihood and internode certainty. For HIV sub-epidemics with 5+ members, the epidemiological parameters were inferred from virus sequence data. The time line for each sub-epidemic was estimated by fitting the BDSKY model and inferring the tree height and internal node ages in the Maximum Clade Credibility time-trees using BEAST2. For each sub-epidemic we estimated the time interval the majority of HIV transmissions occurred in, with corresponding 95% HPD intervals.

Results: We employed the BDSKY model to estimate effective reproductive number *R* and timing of HIV-1C transmissions within 15 sub-epidemics with 5+ members. Only three of the 15 sub-epidemics were estimated as "acute" with recent HIV transmissions. The median estimates of *R* were 0.7–1.6. The V1C5-based informativeness of *R* estimates differed across sub-epidemics. The median peak duration of viral transmissions was 5.4 years (95% HPD, 3.8 to 8.6 years). The median life span of identified HIV sub-epidemics, i.e., the time from the cluster's origin to its most recent sample, was 14.2 years (95% HPD, 9.8 to 16.4 years). The majority of viral transmissions within 15 identified HIV sub-epidemics in Mochudi occurred between 1997 and 2005. The generated data suggests that the time period during which infected people are infectious has decreased significantly since the introduction of ART in Botswana as the national program.

Conclusions: Viral sequence data from a densely sampled community in Botswana allowed us to estimate the effective reproductive number, *R*, and timing of virus transmissions in 15 local HIV sub-epidemics. "Acute" sub-epidemics with recent HIV transmissions are likely to fuel local HIV/AIDS epidemics.

248 Exploring Transmission Dynamics of HIV in Rural KwaZulu-Natal, Using Phylogenetics

Eduan Wilkinson[1]; Siva Danaviah[1]; Justen Manasa[1]; Frank Tanser[1]; Kobus Herbst[1]; Deenan Pillay[2]; **Tulio de Oliveira**[1]
On behalf of the PANGEA_HIV Consortium
[1]*University of KwaZulu-Natal, Durban, South Africa;* [2]*University College London, London, United Kingdom*

Background: Despite antiretroviral rollout, HIV incidence remains high in South Africa. We have observed significant social and geographical heterogeneity in HIV incidence in rural KwaZulu-Natal (Tanser et al. Science 2013). We sought to utilise phylogenetics to better understand the drivers of ongoing transmission in this hyperendemic population. Further, we explore the utility of sampling a fraction of infections to discern changes in incidence, through phylodynamic approaches.

Methods: Viral load was measured in on 2,420 dried blood spots (DBS) testing positive in the population-based surveillance of 2011 and 2012. 749 partial HIV-1 *pol* gene sequences were obtained from DBS samples with a viral load (VL) >10,000. 900 samples were targeted for genotyping (86.0% success rate). Sequences were analysed against all reference strains from South Africa and manually edited prior to phylogenetic inference. The inferred phylogenies were analysed to identify clusters of low genetic diversity (≤ 0.05) corresponding to transmission clusters/pairs, defined by branch support > 98.0%. Clinical, demographic, socio-economic and geographic characteristics of infected individuals were analysed against identified clusters to discern traits associated with transmission. Molecular clock and coalescent analyses were performed in a Bayesian framework order to identify the origin of the clusters and the rate of expansion of the epidemic.

Results: A total of 54 transmission clusters were identified containing 91 women and 37 men. The mean size of clusters was 2.39 (variation 2 - 13). The mean age of women in clusters was 31.55 years and of men, 35.91 years. 24.8% of individuals within the genotypic clusters were recently infected though they comprise approximately 5 % of the cohort. GIS results support the scenario of 'hotspots' of transmission, while coalescent analyses provide further evidence that HIV incidence is decreasing in this population.

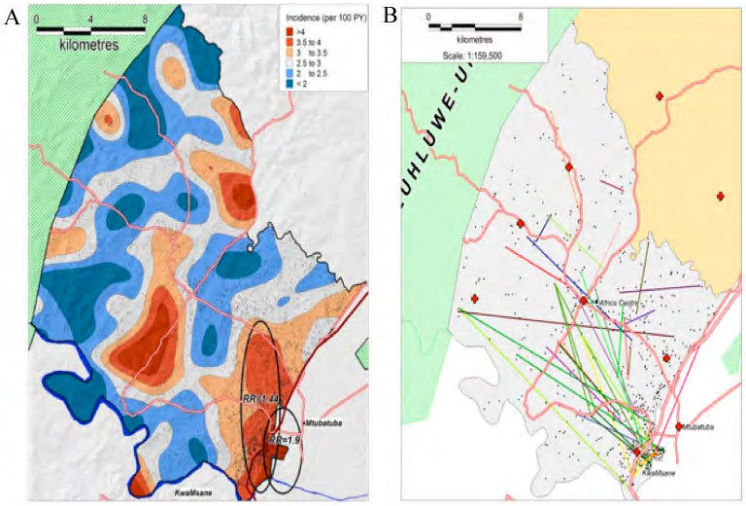


Figure: A) We have used spatial analytical techniques to demonstrate substantial heterogeneity in the epidemic. In terms of HIV-incidence, two high-risk, overlapping spatial clusters were identified in peri-urban communities near the national road. Although the clusters comprise just 5.7% of the study area, they account for nearly one out of every three sero-conversions observed. B) We used genomics data to link HIV-1 infections. The majority of the linkages point to the previously identified hotspots suggesting that those are driving transmission to other areas. Dots represent genotyped individuals. Lines represent linkage.

Conclusions: These results demonstrate the underling complex nature of the dynamics of HIV transmission and that acutely infected patients may disproportionately contribute towards transmissions in the era of increase ARVs. The use of genotypic data coupled with detailed patient information can be used to identify and characterise HIV transmission events. The use of genotypic data analysed within a phylodynamic framework also reflects the decreasing trends in incidence likely due to the scale-up of treatment coverage in recent years.

249 Detecting Changes in Incidence Using Phylogenetic Tools: Simulation-Based Studies Within the PANGEA_HIV Initiative

Emma B. Hodcroft[1]; Oliver Ratmann[2]; Anne Cori[2]; Mike Pickles[2]; Samantha Lycett[3]; Manon L. Ragonnet-Cronin[1]; Matthew Hall[1]; Andrew J. Leigh Brown[1]; Christophe Fraser[2]
On behalf of the Pangea_HIV Consortium
[1]*University of Edinburgh, Edinburgh, United Kingdom;* [2]*Imperial College London, London, United Kingdom;* [3]*University of Glasgow, Glasgow, United Kingdom*

Background: PANGEA_HIV (Phylogenetics and Networks for Generalised HIV Epidemics in Africa) will generate a large volume of next generation viral sequence data from generalized HIV epidemics in sub-Saharan Africa in order to better characterize these epidemics and evaluate HIV prevention efforts. However, the accuracy and reliability of phylogenetic tools to measure aspects of transmission dynamics in these settings is not known.

Methods: The PANGEA_HIV methodology working group conducted a methods comparison exercise in collaboration with multiple, independent research groups to identify the accuracy and power of phylogenetic methods in estimating recent changes in HIV incidence. Two, highly detailed, agent-based epidemiological models capturing generalized HIV transmission dynamics in a village-like, and regional population were developed. Simulated subtype C phylogenies were generated from the transmission tree output which was selected to represent populations varying in HIV incidence dynamics, population size, sampling fraction and model assumptions. Sample datasets of up to several hundred sequences of gag, pol and env for each individual sampled have been generated. These will be coded before distribution to participating collaborators.

Results: First analyses of simple simulated datasets have been performed on pol sequences using a recently developed automated tool ("CPT") which identifies sequence clusters at a maximum genetic distance of 4.5% and bootstrap support of 90%. The samples analysed came from the village model sampled in growth phase (~25 yr post introduction, 4% incidence) and decline (3 yrs after introduction of ART, 2% incidence), with a 20% sampling density. The CPT detected a highly significant decrease in mean cluster size (from 4.13 to 2.76, $p = 0.002$) and an increase in normalised cluster maximum genetic distance (0.0076 to 0.011, $p < 1 \times 10e\text{-}4$), along with a highly significant increase overall in branch lengths (Fig 1).

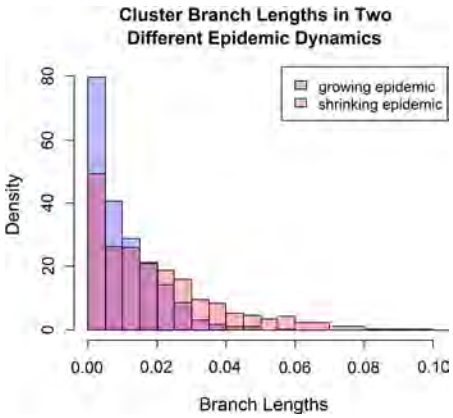

Figure 1 - The mean branch lengths of clusters in a simulated growing epidemic (blue) and simulated shrinking epidemic (pink). The clusters in the shrinking epidemic had a highly significant increase in overall branch length ($p < 2x10e-16$).

Conclusions: We have generated simulated data sets of viral sequences corresponding to samples from hypothetical, generalized HIV-1 epidemic scenarios in sub-Saharan Africa. Initial results show the power of phylogenetic tools to detect changes in incidence and prevalence in the context of generalized HIV epidemics. Further development will focus on using the simulations to test the sample density required by different methodologies to reveal underlying changes in epidemic dynamics.

2:30 pm – 4:00 pm

Transmission Networks: MSM

250 HIV Transmission Among Seattle Adolescents

Joshua Herbeck[1]; Elizabeth Wolf[1]; Stephen van Rompaey[2]; Mari M. Kitahata[2]; Lisa Frenkel[1]

[1]University of Washington, Seattle, WA, US; [2]Center for AIDS Research, Seattle, WA, US

Background: Phylogenetic analyses of HIV gene sequences can be used to infer putative transmission clusters, with associated individual characteristics used to identify risk factors for HIV transmission. We hypothesized that HIV-infected adolescents would be linked to clusters of infected adults.

Methods: Data from time of first HIV genotyping for drug-resistance, including demographics (age, sex, race), HIV transmission risk (men who have sex with men (MSM), MSM & intravenous drug use (IDU), IDU, heterosexual), and homelessness were obtained from the University of Washington (UW) HIV Information System and retrospective chart review. HIV *pol* sequences were obtained from the UW Clinical Virology Laboratory. Phylogenetic clusters were defined as sequences with a shared ancestral node, support values >95% and pairwise genetic distances ≤0.015 nucleotide substitutions per site. The characteristics of all individuals found in clusters were compared to those of non-clustering individuals using multivariable logistic regression. This process was repeated for clusters with ≥1 adolescents (defined at age 13-24 year at first genotyping).

Results: There were 3116 total HIV-1 *pol* sequences from 1960 individuals, including 115 adolescents, genotyped between February 1, 2000 and March 1, 2013. Fifty-four phylogenetic clusters (containing 169 individuals) were identified. In unadjusted analyses, significant associations existed between cluster membership and adolescent age, MSM, and MSM&IDU. In adjusted analyses including transmission risk group, sex, homelessness, and age class at sequencing (adolescent or adult), adolescent age, MSM and MSM&IDU remained significantly associated with cluster membership.

Fifteen clusters were identified that included ≥1 adolescent; adolescents were 75% male, 57% MSM, 7% IDU, and 12% MSM&IDU. Considering those individuals in these clusters that were not adolescents (i.e. individuals that were adults), there was a non-significant positive association between MSM risk group (adults) and cluster membership.

Conclusions: This study suggests that MSM and MSM&IDU adolescents are at particularly high risk of HIV infection and may require specialized HIV prevention services.

251 Characterization of Large Cluster Viral Networks Sustaining the Montreal MSM Epidemic

Bluma Brenner[2]; Ruxandra-Ilinca Ibanescu[2]; Daniela Moisi[2]; Isabelle Hardy[3]; Jean-Pierre Routy[1]; Joanne Otis[4]; Mark Wainberg[2]; Michel Roger[3]

[1]McGill University, Montréal, Canada; [2]Lady Davis Institute, Montreal, Canada; [3]Université de Montréal, Montreal, Canada; [4]UQAM, Montreal, Canada

Background: This study combined phylogenetic, molecular recency, virological and behavioral data to identify key determinants favoring the ongoing genesis of large viral lineages sustaining the Montreal Men having Sex with Men (MSM) epidemic despite widespread antiretroviral therapy coverage and population declines in viral load.

Methods: Phylogenetic analysis ascertained the genetic interrelatedness of MSM viral sequences (2002-2013), first genotyped in primary HIV infection (PHI, 0-6 months, n= 1304) or chronic-untreated (CUN) stage infection (>6 months, n= 1809). Molecular recency assays based on sequence nucleotide ambiguity was nused to estimate recency of infection. Patterns of viral spread were stratified into four distinct groups based on cluster size (1, 2-4, 5-9, 10-91 infections/cluster). PHI cohort participant data ascertained partnership risk behaviour and viremia in four cluster groups. The SPOT rapid testing site cohort determined testing propensity and partnership risk among MSM.

Results: Over the last decade, MSM infections included 1168 solitude transmissions (37%), 244 small clusters (2-4 infections, n=573, 18%), 65 large clusters (5-9 infections, n= 403, 13%), and 45 large cluster (10-91, median 25 infections, n=969, 31%) network. The episodic genesis and spread of clusters was related to primary infection (27%, 46%, 50% and 54%, odds-ratio 1, 2.33, 2.81, 3.33, respectively). Viral lineages associated with unique, small, large (5-9) and (10-91) cluster groups showed significant differences in weighted sequence ambiguity (0.40%, 0.27%, 0.20%, 0.13%, respectively). PHI cohort data revealed extended viremia over 24 months in lineages associated with large cluster networks. The MSM epidemic is growing in younger populations, with 14%, 18%, 27%, and 32% of unique, small, large (5-9) and large (10+) below 30 years of age, respectively. PHI cohort data

show no significant differences in partnership risk behaviours in the four cluster groups. SPOT cohort data showed an inverse relationship between partnership risk behaviour and testing propensity.

Conclusions: The Montreal MSM epidemic is sustained by primary/recent stage infection with an ongoing genesis of large cluster viral lineages (median 16 infections/cluster) showing protracted infectivity. Overall 7% of lineages account for 70% of onward transmissions. These findings substantiate the need for frequent testing among increasingly younger and mixed risk MSM populations.

252 Sources of HIV-1 Transmission in the Ongoing, Concentrated HIV Epidemic Among Men Having Sex With Men in the Netherlands Between July 1996 and December 2010

Oliver Ratmann[1]; Ard van Sighem[2]; Daniela Bezemer[2]; Alexandra Gavryushkina[3]; Peter Reiss[2]; Frank de Wolf[1]; **Christophe Fraser**[1]

[1]Imperial College London, London, United Kingdom; [2]Stichting HIV Monitoring Foundation, Amsterdam, Netherlands; [3]University of Auckland, Auckland, New Zealand

Background: The HIV epidemic among men having sex with men (MSM) remains out of control. To better target HIV prevention efforts, it is critical to quantify the proportion of HIV transmissions that originate throughout the HIV treatment cascade, from undiagnosed to treated individuals.

Methods: We conducted a combined analysis using anonymized, molecular genetic and clinical data from HIV infected individuals in care in the Netherlands between 1996 and 2013. Patients were followed at high frequency in the open, national opt-out, clinical ATHENA cohort. Partial HIV-1 *pol* sequences were collected for 46% of all MSM in care. Using viral evolutionary analyses, we determined potential transmitters to 667 recipient MSM that were diagnosed with recent HIV infection up to December 2010. Using clinical data, we associated treatment cascade stages with potential transmission intervals.

Results: A total of 1,660 person-years of potential transmission intervals were associated with phylogenetic evidence for direct HIV-1 transmission. Overall, the estimated proportion of transmissions from undiagnosed individuals decreased from 66% (95% confidence interval: 52-79%) from May 2006 to December 2007 to 58% (43%-74%) from July 2009 to December 2010, while the estimated proportion of transmissions from individuals after ART initiation increased from 8% (4-12%) to 17% (12-22%) in the same observation periods. Considering the most recent period July 2009 to December 2010, 15% (10-20%) of all transmissions are estimated to originate from undiagnosed individuals with recent HIV infection at diagnosis, 24% (19-29%) from those undiagnosed with chronic HIV infection at diagnosis, 19% (14-25%) from those undiagnosed with no data on recency of HIV infection, 4% (2-5%) from diagnosed, recently infected individuals within the first 3 months after diagnosis, 6% (4-8%) from diagnosed untreated individuals with CD4 count >500, 15% (12-19%) from diagnosed, untreated individuals with CD4 count <500, and 10% (7-12%) from treated individuals with a viral load above 50 copies/ml plasma blood.

Conclusions: Due to its national opt-out policy, the open, clinical ATHENA cohort enabled the worldwide largest analysis to date into the sources of HIV infection amongst MSM. A combined approach appears to be required to bring this HIV epidemic under control, including expanded testing, universal ART coverage, and frequent monitoring of the treated population.

253 A Direct Comparison of Two Densely Sampled Western European HIV Epidemics: The UK and Switzerland

Manon L. Ragonnet-Cronin[1]; Mohaned Shilaih[2]; Huldrych F. Günthard[2]; Jurg Boni[2]; Sabine Yerly[3]; Valerie Delpech[4]; David Dunn[5]; Roger Kouyos[2]; Andrew J. Leigh Brown[1]
Swiss HIV Cohort Study/UK HIV Drug Resistance Database

[1]University of Edinburgh, Edinburgh, United Kingdom; [2]University Hospital Zurich, Zurich, Switzerland; [3]University Hospital Geneva, Geneva, Switzerland; [4]Public Health England, London, United Kingdom; [5]MRC CTU at UCL, London, United Kingdom

Background: The UK and Swiss (CH) HIV epidemics have both historically been driven by transmission of subtype B among men who have sex with men (MSM). The CH population is 1/8 the size of the UK and HIV prevalence in CH is nearly double that of the UK. Both epidemics are densely sampled, by the UK HIV Drug Resistance Database and the Swiss HIV Cohort Study respectively. Previous independent analyses have suggested dramatically different epidemic dynamics.

Methods: A bioinformatics pipeline to compare HIV transmission patterns was developed which included: maximum likelihood phylogenetic trees for subtype A1, B and C *pol* sequences against a background of global sequences; cluster detection at a range of bootstrap (70%-95%) and genetic distance (1.5% and 4.5%) thresholds; analysis of degree distributions by risk group and characterisation of HIV import for each country independently. We use univariate and multivariate logistic regression to predict cluster membership based on country, sampling date, risk group, ethnicity and sex.

Results: We analysed >8000 subtype B sequences from CH and >25000 from the UK. A genetic distance of 1.5% yielded mainly pairs in both. Clustering was much higher among UK sequences at all thresholds (35% vs 15% on average, $p<10^{-91}$) suggesting that the UK database is more likely to capture transmitting partners. The number of links for each clustered sequence (degree distribution) followed a power law in both, but shifted downwards for CH relative to the UK. Down sampling the UK dataset to match the size of the CH dataset revealed a more similar degree distribution ($p<10^{-5}$ vs $p<10^{-12}$), remaining higher for the UK in MSM ($p<10^{-8}$), but not for heterosexuals ($p=0.2$). Adjusting for sampling time in the logistic regression models reduced the clustering odds-ratio between countries from 3.1 to 2.2. Both countries showed extensive intermixing with other European countries (80% of direct links for CH and 60% for UK), and the UK also displayed linkage with other Anglophone countries (Australia, Canada and USA, 26% of links). Within Europe, Spain was the most frequently linked country (12% and 15% of all links for the UK and CH, respectively).

Conclusions: In conclusion, epidemic size, insularity and sampling time play a part in explaining the differences in clustering patterns between the CH and UK epidemics. Reduced clustering in CH is most significant among MSM, who seem more likely to have acquired the virus outside the country.

Session P-B5 Poster Session **Poster Hall**

2:30 pm – 4:00 pm

Next Generation of Next-Generation Sequencing

254 Present Applications of a High-Throughput, Single Measure HIV Genomic Incidence Assay

Sung Yong Park[1]; Tanzy Love[2]; Nolan Goeken[1]; Robert Bolan[3]; Alan S Perelson[4]; Michael Dube[1]; **Ha Youn Lee**[1]

[1]Keck School of Medicine at University of Southern California, Los Angeles, CA, US; [2]University of Rochester School of Medicine and Dentistry, Rochester, CA, US; [3]Los Angeles Gay and Lesbian Center, Los Angeles, CA, US; [4]Los Alamos National Laboratory, Los Alamos, CA, US

Background: Annual HIV incidence is the primary assessor for monitoring the epidemic's rise and decline. In pursuit of an accurate assay, we have proposed a genomic incidence assay utilizing fingerprints harbored in the HIV sequence population, which showed over 95% accuracy among 182 incident and 43 chronic samples. Still, two major hurdles must

be overcome before routine use in cross-sectional settings: 1) streamlining the cost and workflow, 2) ensuring proper classification between multiple-founder recent infections and chronic infections.

Methods: For enhancing the cost efficiency of the sequence-based assay, we developed a high-throughput next-generation sequencing platform; a signal-masking bioinformatics pipeline was devised to analyze 18,434 envelope gene segments (HXB2 7212-7601) obtained from 12 incident and 24 chronic patients. To give the assay power to appropriately discriminate multiple-founder recent infections from chronic infections, we formulated a mathematical model which posits the intersequence nucleotide base difference distribution of each subject's sequence sample as a function of infection duration and the number of founder sequences. This model was tested by analyzing HIV subtype B and C samples from 40 incident subjects with multiple founder viruses.

Results: First, the cost-effective pyrosequencing platform correctly classified all 12 incident subjects (100% sensitivity) and 23 out of 24 chronic subjects (96% specificity). Our signal-masking bioinformatics pipeline yielded a process error rate of 5.8×10^{-4} per base. Sampling simulations showed that the biomarkers were tolerant of the two factors most likely to affect the accuracy: sequencing errors and template resampling. Second, a quantitative guideline for segregating viral lineages was provided by our mathematical model, enabling us to assess when each subject was infected. The infection periods obtained from our model estimates and from Fiebig laboratory staging showed a statistically significant linear relationship ($p<0.0005$), correctly identifying all 40 individuals with incident infections.

Conclusions: The high-throughput platform permits the assay to be cost-effective, and when it is combined with our mathematical model, we can obtain recency signatures from the complex gene pool that arises from multiple founder viruses. Our sequence-based approach marks significant progress towards accurate determination of HIV incidence from genomic readouts measured from cross-sectional samples from a single blood draw.

255 A Comprehensive Analysis of Primer IDs to Study Heterogenous HIV-1 Populations

David Seifert[1]; Armin Töpfer[1]; Francesca Di Giallonardo[2]; Stefan Schmutz[2]; Huldrych F. Günthard[2]; Volker Roth[3]; Niko Beerenwinkel[1]; Karin J. Metzner[2]
[1]ETH Zurich, Basel, Switzerland; [2]University Hospital Zurich, Zurich, Switzerland; [3]University of Basel, Basel, Switzerland

Background: Haplotyping of HIV-1 populations is an essential step to better understand the evolutionary dynamics of the virus. With the advent of next-generation sequencing (NGS), haplotyping of viral populations has become feasible. Since HIV-1 is highly heterogeneous, several statistical methods have been devised to deal with error-prone NGS data, however, they often do not capture the population correctly. In order to correct for errors, the use of PrimerIDs (primer identifiers) has been proposed. Here, we used PrimerIDs to systematically estimate different enzymatic error rates and to comprehensively study the feasibility of PrimerIDs.

Methods: Plasmids containing full-length genomes of 5 HIV-1 clones were separately amplified in bacteria and then transfected into 293T cells. Generated infectious HIV-1 particles were pooled, DNase treated, and a fragment of the *pol* gene was reverse transcribed with SuperScript III reverse transcriptase (RT) and primers containing random 10-mers. Reverse transcription was performed in six independent replicates. Subsequently, nested PCR was performed using Platinum Taq DNA Polymerase followed by adapter ligation and sequencing with Illumina MiSeq.

Results: From an average number of 1.1 million reads, we called consensus sequences for PrimerIDs, each supported by at least 10 sequencing reads, to yield on average 11,000 consensus sequences per replicate. From these consensus sequences, we could call all mutant bases from the five reference viruses. We estimated a RT error rate of 6.23e-4 (95% CI: [6.13e-4, 6.32e-4]). We inferred the recombination rate of the RT to be 3.44e-5 (95% CI: [2.26e-5, 4.92e-5]). The PCR substitution rate of 1.18e-4 (95% CI: [1.14e-4, 1.22e-4]) was determined from those mutants having arisen in the first cycle of the PCR. We calculated the total number of transcribed RNAs to be on the order of 60,000 from the observed collision rate of 2%. We observed no sequence-specific bias in PrimerID frequencies, the same RT efficiencies as compared to commonly used short, specific RT primers, and no effects of primerIDs on the estimated distribution of the five viruses in the mix.

Conclusions: PrimerIDs allow for determining error rates in RT-PCR-NGS protocols and are applicable to study HIV-1 heterogeneity when attention is paid to collision rates. Given these advantages, the protocol is still labor- and cost-intensive and does not significantly improve on the variance of frequency estimates.

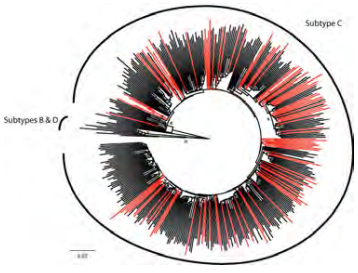
256 Near Full Length HIV-1 Sequencing to Understand HIV Phylodynamics in Africa in Real Time

Siva Danaviah; Justen Manasa; Eduan Wilkinson; Sureshnee Pillay; Zandile Sibisi; Sthembiso Msweli; Deenan Pillay; **Tulio de Oliveira**
University of KwaZulu-Natal, Durban, South Africa

Background: HIV transmission continues in Africa at alarming rates despite biological and behavioural interventions. Understanding the drivers of HIV transmission and evolution and translating the results into effective interventions is a key component of halting the epidemic. Recent technological advancement in complete genome sequencing has expanded the breadth and speed of genomic analyses currently possible. We have constructed a high-throughput genomics and bioinformatics pipeline that has successfully generated high quality complete HIV genomes in a hyper-endemic region of South Africa (SA), through the PANGEA_HIV Consortium

Methods: HIV RNA was extracted from plasma from patients failing antiretroviral therapy, within the Africa Centre (AC) research area and 4 overlapping regions spanning the 9.7kb complete HIV genome were amplified in a one-step RT-PCR strategy optimised for subtype C virus. Pooled amplicons were sequenced on an Illumina MiSeq. Fragments were quality controlled with SMALT software and assembled using two independent strategies (de novo and mapping to reference) in Geneious. Resulting consensus sequences were aligned against published HIV complete genomes from South Africa (n=300). Bayesian and maximum likelihood trees with branch support were reconstructed in PhyML and MrBayes.

Results: Amplification success rate of complete genomes, on samples with viral loads >10,000 c/ml was 85%. Near complete HIV genomes were generated for 117/117 samples sequenced thus far, with all nine open reading frames, the U5 / partial R region of the 5' LTR and partial U3 of the 3' LTR represented. Coverage of the HIV genome averaged 99.9% with a mean depth of coverage of 15 539 times (range = 21-48 767 times). Phylogenetic reconstruction confirmed that the AC strains were all HIV-1 subtype C where 36/117 sequences clustered with other complete genomes from SA. The discrete AC clusters (n=22) suggested multiple independent introductions of subtype C into the surveillance area and onward transmission within the population.



Maximum likelihood tree of 117 Africa Centre near full length HIV-1 complete genomes and 300 HIV-1 C genomes from South Africa. The tree is rooted on reference strains of subtypes B & D, branch support (bootstrap > 90) are marked with an *.

Conclusions: This is the first report, to the best of our knowledge, of a high-throughput complete HIV genome sequencing and analysis pipeline in Africa. The genetic diversity of HIV variants in this population is high and is mediated primarily by multiple introductions of HIV. Interventions therefore must be cognizant of the dynamics that drive these independent introductions in order to impact on going HIV transmission.

257 Pan-HIV Next-Gen Sequencing Strategy for Viral Surveillance

Michael G. Berg[1]; Julie Yamaguchi[1]; Elodie Alessandri-Gradt[2]; Jean-Christophe Plantier[2]; Catherine Brennan[1]

[1]Abbott Laboratories, Abbott Park, IL, US; [2]Virology Unit, National Reference for HIV, Rouen, France

Background: The complexity of HIV strains has increased significantly due to natural evolution and inter-subtype recombination; recombination is now a worldwide problem. Thus, complete genome sequencing is essential to monitor HIV diversity accurately within populations. Next-generation sequencing (NGS) has the potential to revolutionize strategies for HIV surveillance. We have developed a universal method that permits full genome sequencing of all HIV-1 groups (M, N, O, and P) and HIV-2.

Methods: Reverse transcription primers, designed in conserved regions of HIV and spaced at 1.5-2kb intervals, fuse viral sequences to a common adaptor (SMART) sequence. This same adaptor is added to the 3' end of the cDNA to permit PCR amplification of libraries, which are then tagmented with Nextera XT for multiplexing and sequencing on an Illumina MiSeq. HIV sequences are extracted and assembled in CLC-Bio software (Qiagen) and classified by phylogenetic analysis using PHYLIP and SIMPLOT.

Results: Broad application of the approach was demonstrated using a panel of virus isolates (n=47) derived from cell culture that included 27 group M (different subtypes and CRFs), 16 O, 2 N, 1 P, and 1 HIV-2. In a single run multiplexing 23 libraries, 100% genome coverage was obtained for each at a median depth of 2100X, with HIV reads comprising 9.4% (median) of the total. A Cameroonian HIV-1 non-subtype B specimen was used to optimize the protocol for plasma. An NGS run of 8 high titer ($>5.0_{log}$ copies/ml) clinical specimens, infected with diverse group M subtypes, yielded 96-100% coverage for each at a median 433X depth. Method sensitivity, demonstrated by serial dilution, showed that >50% of a genome could be obtained from a clinical specimen with a viral load $\geq 3.8_{log}$ copies/ml (100 RNA copies input). Due to inherent variability in sample background, coverage varied widely among specimens with viral loads $<4.5_{log}$. Nevertheless, sufficient sequence was obtained for strain classification. From the 55 novel full-length HIV sequences determined in this study, 5 are unique recombinants.

Conclusions: The HIV-SMART approach harnesses the specificity of HIV-directed priming without *a priori* knowledge of the viral strain present. This technology provides an unparalleled opportunity to identify diverse HIV strains in patient specimens and to determine phylogenetic classification based on the entire viral genome, illustrating the utility of NGS for viral surveillance.

258 PCR-Free Full Genome Characterization of Diverse HIV-1 Strains by Nextgen Sequencing

Viswanath Ragupathy[1]; Feng Gao[2]; Ana Sanchez[2]; Marco Schito[3]; Thomas Denny[2]; Michael Busch[4]; Jiangqin Zhao[1]; Christelle Mbondji[1]; SaiVikram Vemula[1]; Indira Hewlett[1]

[1]US Food and Drug Administration, Silver Spring, MD, US; [2]Duke Human Vaccine Institute and Departments of Medicine, Duke University Medical Center, Durham, NC, US; [3]Henry Jackson Foundation, DAIDS, NIAID, Bethesda, MD, US; [4]Blood Systems Research Institute/University of California San Francisco, San Francisco, CA, US

Background: HIV-1 genotyping is an important tool for clinical and epidemiological studies. High level of genetic variation, recombination and mutations pose difficulty in successful PCR amplification of HIV-1 genomes. In addition, new emerging subtypes may not be detected with standard PCR primers. Here, we report a novel PCR-free multiplex method for characterization of full length HIV-1 genomes (~9.7kb) using the Nextgen RNA Seq approach.

Methods: A total of 27 diverse HIV-1 strains representing subtypes A-G, CRFs, URFs and Group O were obtained from the Global HIV-1 diversity panel that was assembled at the Duke EQAPOL. Viral RNA was extracted, reverse transcribed as described in the Illumina Truseq RNA Kit and sequenced using the MiSeq platform. Sequence reads were quality filtered and reference mapped using CLC genomic work bench software v6.0.4. Consensus sequences were generated for each virus and used for phylogenetic tree analysis using the neighbor-joining method based on the Kimura two-parameter substitution model and recombination patterns were determined using Simplot. Drug resistance was inferred from the Stanford HIV drug resistance program, and co-receptor usage was determined using the Geno2Pheno (g2p) 5-10% FPR.

Results: The multiplex RNA sequencing approach yielded >10000x coverage for each of the viral genomes. Pools of viral isolates were de-multiplexed and discriminated using bio-informatics. After filtering reads specific for HIV-1, each position in the viral genome had >1000x coverage. This approach enabled reconstruction of whole genome HIV-1 haplotypes accurately including flanking LTRs. Analysis of full HIV-1 genome sequences using Simplot correctly identified 15 pure subtypes, one Group O virus, and recombination patterns of 8 CRFs and 3 URFs. All these HIV subtypes identified were comparable to Sanger sequencing. In addition, this approach revealed NNRTI, integrase and protease drug-specific minor variants and drug resistance mutations with >1000x coverage. The g2p analysis predicted 89% of isolates as being R5 tropic, and the remaining were identified as X4 tropic.

Conclusions: We have developed a reliable, PCR-free and multiplexing approach to characterize whole HIV-1 genome sequences. This novel PCR-free method can be used for characterization of new, emerging unknown subtypes or recombinants and to reduce PCR-derived sequence errors. The multiplexing approach makes this NGS method more cost-effective and less labor-intensive than conventional methods.

259 Full-Length Env Deep Sequencing in a Donor With Broadly Neutralizing V1/V2 Antibodies

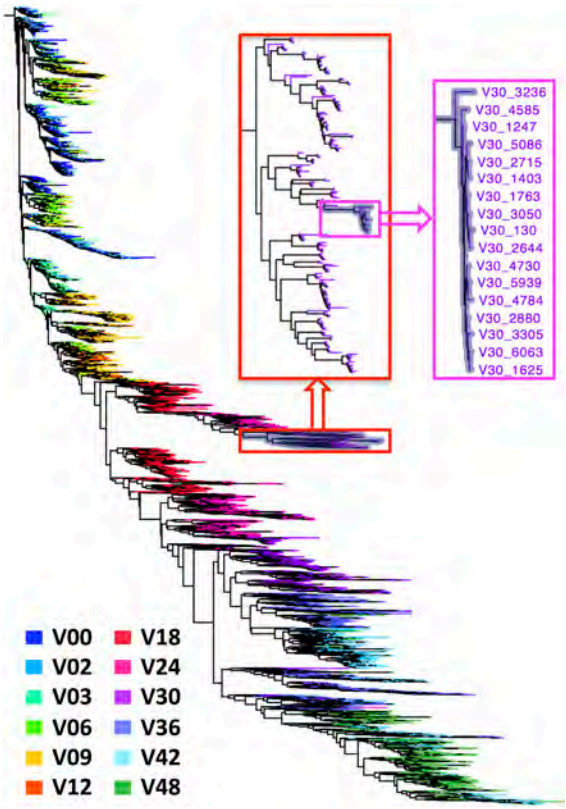
Ben Murrell[1]; Melissa Laird[2]; Elise Landais[3]; Caroline Ignacio[1]; Ellen Paxinos[2]; Pham Phung[4]; Sergei L. Kosakovsky Pond[1]; Douglas D. Richman[1]; Pascal Poignard[3]; Davey M. Smith[1]

[1]University of California San Diego, La Jolla, CA, US; [2]Pacific Biosciences, Menlo Park, CA, US; [3]The International AIDS Vaccine Initiative Neutralizing Antibody Center, La Jolla, CA, US; [4]LabCorp, South San Francisco, CA, US

Background: Understanding the co-evolution of HIV populations and broadly neutralizing antibody (bNAb) lineages may inform vaccine design. Novel long-read, next-generation sequencing methods allow, for the first time, full-length deep sequencing of HIV *env* populations.

Methods: We longitudinally examined *env* populations (12 time points) in a subtype A infected individual from the IAVI primary infection cohort (Protocol C) who developed bNAbs (62% ID50>50 on a diverse panel of 105 viruses) targeting the V1/V2 region. We developed a Pacific Biosciences single molecule, real-time sequencing protocol to deeply sequence full-length *env* from HIV RNA. Bioinformatics tools were developed to align *env* sequences, infer phylogenies, and interrogate escape dynamics of key residues and glycosylation sites. PacBio *env* sequences were compared to *env* sequences generated through amplification and cloning. *Env* dynamics were interpreted in the context of the development of a V1/V2-targeting bNAb lineage isolated from the donor.

Results: We collected a median of 6799 high quality full-length *env* sequences per timepoint (median per-base accuracy of 99.7%). A phylogeny inferred with PacBio and 100 cloned *env* sequences (10 time points) found cloned *env* sequences evenly distributed among PacBio sequences. Phylogenetic analyses also revealed a potential transient intra-clade superinfection visible as a minority variant (~5%) at 9 months post-infection (MPI), and peaking in prevalence at 12MPI (~64%), just preceding the development of heterologous neutralization. Viral escape from the bNAb lineage was evident at V2 positions 160, 166, 167, 169 and 181 (HxB2 numbering), exhibiting several distinct escape pathways by 40MPI.



Maximum likelihood phylogeny of the primary infection clade, inferred from longitudinal full-length deep sequenced HIV *env*. Terminal branches are colored by sample date (numbers in legend represent months post infection). Inset boxes show successively expanded phylogenetic detail, highlighting the sequencing depth. Very short terminal branches suggest low sequencing error rates.

Conclusions: Our PacBio full-length *env* sequencing method allowed unprecedented characterization of *env* dynamics and revealed an intra-clade superinfection that was not detected through conventional methods. The importance of superinfection in the development of this donor's V1/V2-directed bNAb lineage is under investigation. Longitudinal full-length *env* deep sequencing allows accurate phylogenetic inference, provides a detailed picture of escape dynamics in epitope regions, and can identify minority variants, all of which may prove useful for understanding how *env* evolution can drive the development of antibody breadth.

The Gut Microbiome

260 Functional Profiling of the Gut Microbiome in HIV Infection

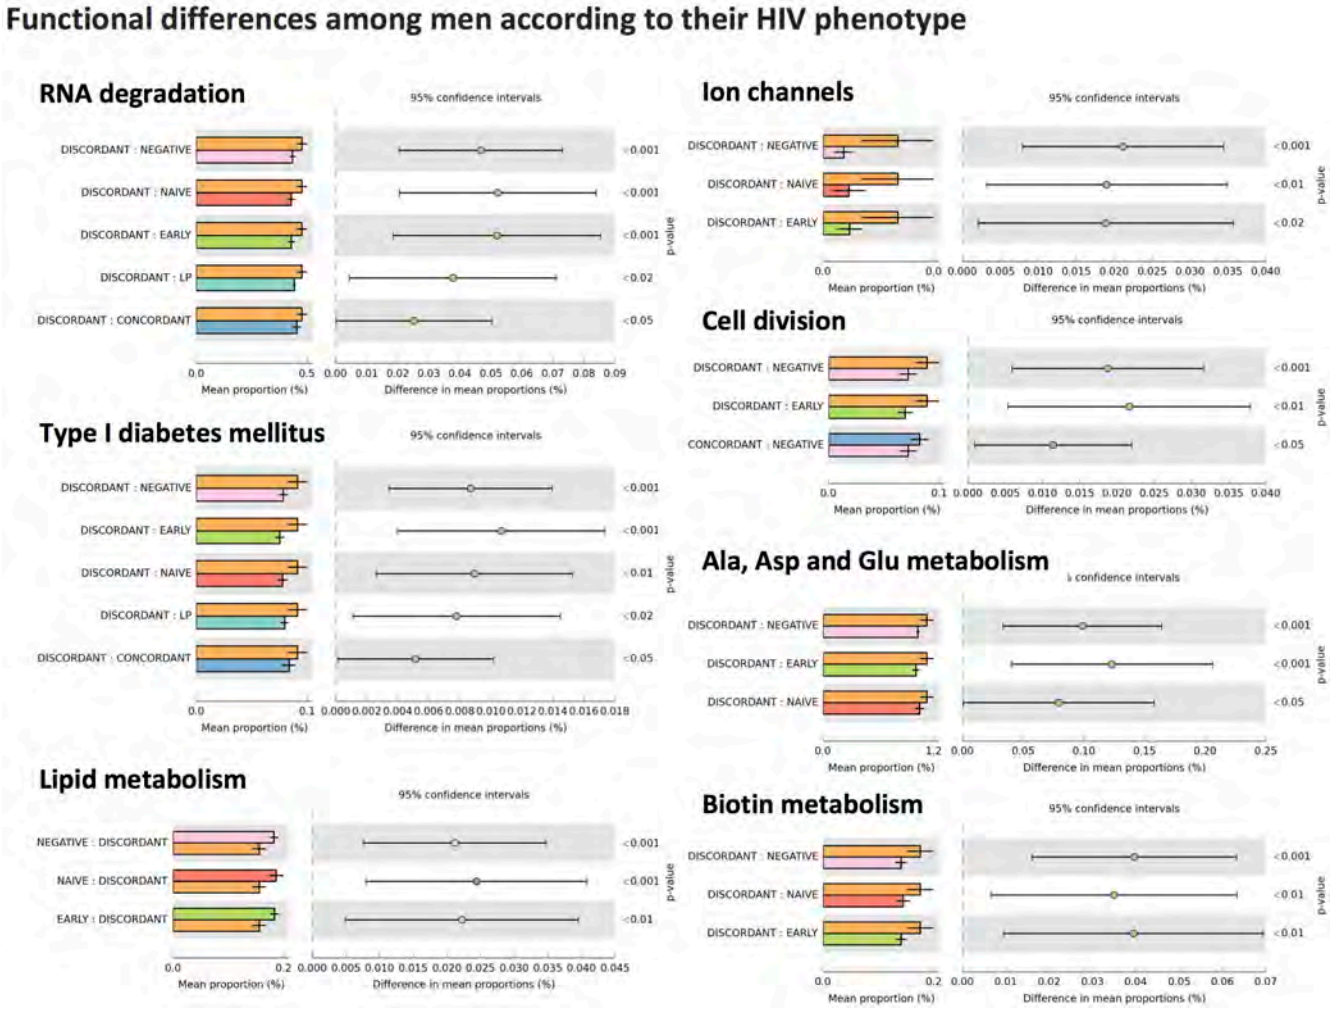
Yolanda Guillén; Marc Noguera-Julian; Muntsa Rocafort; Mariona Parera; Maria Casadellà; Isabel Bravo; Josep Coll; Julià Blanco; Bonaventura Clotet; Roger Paredes
MetaHIV Study Group

IrsiCaixa AIDS Res Inst, Hosp Univ Germans Trias i Pujol, Univ Autònoma de Barcelona, Badalona, Spain

Background: The gut microbiome plays an essential role in human physiology. We investigated to what extent HIV infection could modify its functions.

Methods: We used PICRUSt to infer the functional profile from 16S rRNA Miseq™ data, which was obtained in a cross-sectional study comparing the intestinal microbiome of HIV-negative (HIVneg) and HIV-1-infected subjects with different phenotypes, i.e., late presenters (LP: no ART, CD4≤200 c/mm^3), elite controllers (EC: no ART, HIV-1 RNA (VL)<50 c/mL for 1 year), viremic controllers (VC: no ART, VL 50-2000 c/mL for 1 year), ART-naïve (AN: no ART, CD4≥500 c/mm^3, VL>2000 c/mL), early treated (ET: ART started ≤6 months from HIV-1 infection, VL<50 c/mL), immune concordant (IC: on ART≥2 years, CD4≥500 c/mm^3, VL<50c/mL), and immune discordant (ID: on ART≥2 years, CD4≤300 c/mm^3, VL<50c/mL). Comparisons involving >2 groups were done using ANOVA plus Benjamini-Hochberg correction and Tukey-Kramer post-hoc tests; 2-group comparisons were performed with the Welch's t-test (STAMP package).

Results: The parent study included 80 subjects: 58 men, 21 women and 1 transgender woman. Relative to men, women showed significant enrichment in amino acid and carbohydrate metabolism, and in functions related to nervous and excretory systems. Within men, HIV+ subjects (5 LP, 1 EC, 3 VC, 6 AN, 5 ET, 17 IC, 8 ID) showed enrichment in functions related to membrane transport; Ala, Asp and Glu metabolism, and primary and secondary bile acid biosynthesis, as well as decreased lipid metabolism, relative to HIVneg (n=13). Most differences among HIV+ men involved the ID group (Figure), whose microbiome was enriched for genes related to RNA degradation; type I diabetes mellitus; ion channels; cell division; Ala, Asp and Glu metabolism, and biotin metabolism, and depleted in lipid metabolism. In addition, the microbiome of MSM (n=46) was enriched for carbohydrate and aminoacid metabolism, nervous and immune system functions, and depleted in biosynthesis of secondary metabolites, relative to MSW (n=9) and PWID (n=3) men. No differences were found by current or nadir CD4+ counts. Contrasting with previous reports, we found no differences in the tryptophan pathway in any of the former comparisons.



Conclusions: HIV infection, but also gender and sexual behavior influence gut microbiome functions. In particular, HIV infection is associated with bidirectional unbalances in intestinal metabolic activity, which do not seem to involve the tryptophan pathway.

261 Gut Microbiota Correlates with HIV-1 Control and Immune Status

Muntsa Rocafort; Marc Noguera-Julian; Yolanda Guillén; Mariona Parera; Maria Casadellà; Isabel Bravo; Josep Coll; Julià Blanco; Bonaventura Clotet; Roger Paredes
MetaHIV-Pheno Study Group
IrsiCaixa AIDS Res Inst, Hosp Univ Germans Trias i Pujol, Univ Autònoma de Barcelona, Badalona, Spain

Background: Recent studies suggest a role of the gut microbiome on HIV/AIDS pathogenesis, but it is unknown if the gut microbiota differs by HIV-1 control and immune status, or if antiretroviral treatment (ART) affects the intestinal microbial content to any extent.

Methods: This cross-sectional study compared HIV-1-negative (HIVneg) subjects with HIV-1-infected individuals with the following phenotypes: late presenters (LP: no ART, CD4≤200 c/mm^3), elite controllers (EC: no ART, HIV-1 RNA (VL)<50 c/mL for 1 year), viremic controllers (VC: no ART, VL 50-2000 c/mL for 1 year), ART-naïve (AN: no ART, CD4≥500 c/mm^3, VL>2000 c/mL), early treated (ET: on ART started ≤6 months from HIV-1 infection, VL<50 c/mL), immune concordant (IC: on ART≥2 years, CD4≥500 c/mm^3, VL<50c/mL), and immune discordant (ID on ART≥2 years, CD4≤300 c/mm^3, VL<50c/mL). Participants were 18-60 years old, had body mass index 18.5-30 and, except for LP, had no antibiotic usage during the previous 3 months. The fecal microbiota was characterized by massive 16S rRNA sequencing (MiSeq™). Richness (Sobs, Chao1 and ACE estimators), diversity (Shannon and Simpson indexes) and microbial taxonomic analyses were performed using Mothur and R/Vegan software packages.

Results: The study included 80 individuals: 16 HIVneg and 64 HIV-1+ (5 LP, 3 EC, 6 VC, 7 AN, 5 ET, 27 IC, and 11 ID). Compared with HIVneg, the gut microbiome of HIV-1+ subjects had lower richness and diversity (Table). By HIV-1 phenotype, IC, ID, EC, VC and LP had less observed OTUs (S_{obs}) and lower Shannon diversity than HIVneg, although the latter comparison was not statistically significant for EC. At the phylum level and relative to HIVneg, there were significant decreases in Firmicutes in IC, ID and LP; reductions in Lentisphaerae in IC, ID and VC, and increases in Bacteroidetes in ID. Proteobacteria were reduced in EC and increased in ET. The Firmicutes family Ruminococcaceae decreased in ID and LP. Among the Bacteroidetes families, Bacteroidaceae increased in IC, ID and EC; Porphyromonadaceae increased in IC and ID and Prevotellaceae decreased in IC, ID and EC. Both ET and AN remained similar to HIVneg across comparisons.

	Richness			Diversity	
	Sobs	Chao1	ACE	Shannon	Simpson
HIVneg	431.5	1906.18	1645.54	4.18	0.94
All HIV+	328 ***	1749.07 *	1359.41 **	3.72 ***	0.93 *
LP	322 **	1771.11	1488.09	3.59 **	0.91
EC	275 **	1755.50	1084.09 **	3.41	0.93
VC	299.5 ***	1937.81	1469.57	3.29 **	0.93 **
AN	372	2636.79	1572.28	4.25	0.95
ET	414	1759.54	1409.11	4.53	0.97
IC	330 ***	1643.52 **	1316.28 **	3.92 **	0.94
ID	250 ***	1389.50 *	1205.35 ***	3.46 ***	0.90 **

Median values are shown. Uncorrected Wilcoxon p-values, relative to HIVneg: *p=0.05-0.1, **p=0.01-<0.05; ***p<0.01.

Conclusions: Bacterial gut microbiota composition differs by HIV-1 phenotype and is affected by ART and immune recovery. Initiation of ART while CD4+ remain >500 cells/mm^3 and, particularly, during the first 6 months following HIV-1 infection preserve the gut bacterial content.

262 Butyrate Reduces Pathobiont-Associated HIV-1 Infection and Activation of Gut T Cell

Jon Kibbie; Stephanie Dillon; Eric Lee; Charles Robertson; Daniel N. Frank; Martin McCarter; Cara C. Wilson
University of Colorado Anschutz Medical Campus, Aurora, CO, US

Background: We previously reported that untreated chronic HIV-1 infection is associated with an altered intestinal microbiome that was linked to mucosal and systemic inflammation. HIV-1-infected (HIV+) subjects had increased abundances of pathobionts (e.g. Prevotella) and decreased abundances of bacterial families that contain butyrate-producing bacterial species (BPB). Butyrate is a short chain fatty acid important in intestinal immune regulation. We hypothesized that butyrate would decrease pathobiont-driven mucosal inflammation and investigated this using an *ex vivo* intestinal cell model.

Methods: Species identification was performed on bacterial 16S ribosomal DNA sequences previously obtained from colon biopsies of 17 untreated chronic HIV+ and 14 uninfected (HIV-) subjects. For analysis, the percent abundances of known colonic BPB (n=15 species) were pooled for each subject. Lamina propria mononuclear cells (LPMC) from normal human intestinal tissue (n=7) were infected with HIV-1_{BaL} and cultured with *P. stercorea* and butyrate: 0mM, 0.2mM (low) or 2mM (physiologic). Measurements of CD4 T cell activation (CD38+HLA-DR+) and infection (intracellular Gag-p24; ip24) were performed by flow cytometry. Levels of T cell-associated cytokines IFNγ, IL-17 and IL-2 were measured by ELISA. t-tests were used for statistical analysis.

Results: Abundances of BPB were lower in HIV+ subjects compared to HIV- controls (p=0.009). In HIV-1_{BaL}-infected LPMC, without butyrate, *P. stercorea* increased T cell activation (p=0.005), induced IFNγ (p=0.005), IL-17 (p=0.001) and IL-2 (p=0.03) production and increased frequencies of ip24$^+$ CD4 T cells (p<0.0001). With 2mM butyrate, *P. stercorea*-associated T cell activation was decreased by 85% (p<0.05), production of IFNγ (p<0.01), IL-17 (p<0.01) and IL-2 completely abrogated, and T cell infection levels decreased 3-fold (p=0.01). Lower butyrate concentrations failed to inhibit *P. stercorea*-induced T cell activation and infection, induced a 2-fold decrease in IFNγ and IL-17 (p<0.05), but increased IL-2 production.

Conclusions: Untreated, chronic HIV+ subjects have decreased abundances of BPB in the colonic mucosa. In an *ex vivo* intestinal cell model, physiological levels of butyrate decreased T cell activation, cytokine production and HIV infection induced by *P. stercorea*, a pathobiont increased in the colonic mucosa of HIV+ subjects, whereas lower levels did not. These findings suggest that a loss of BPB in the gut microbiome may contribute to HIV-associated mucosal pathogenesis.

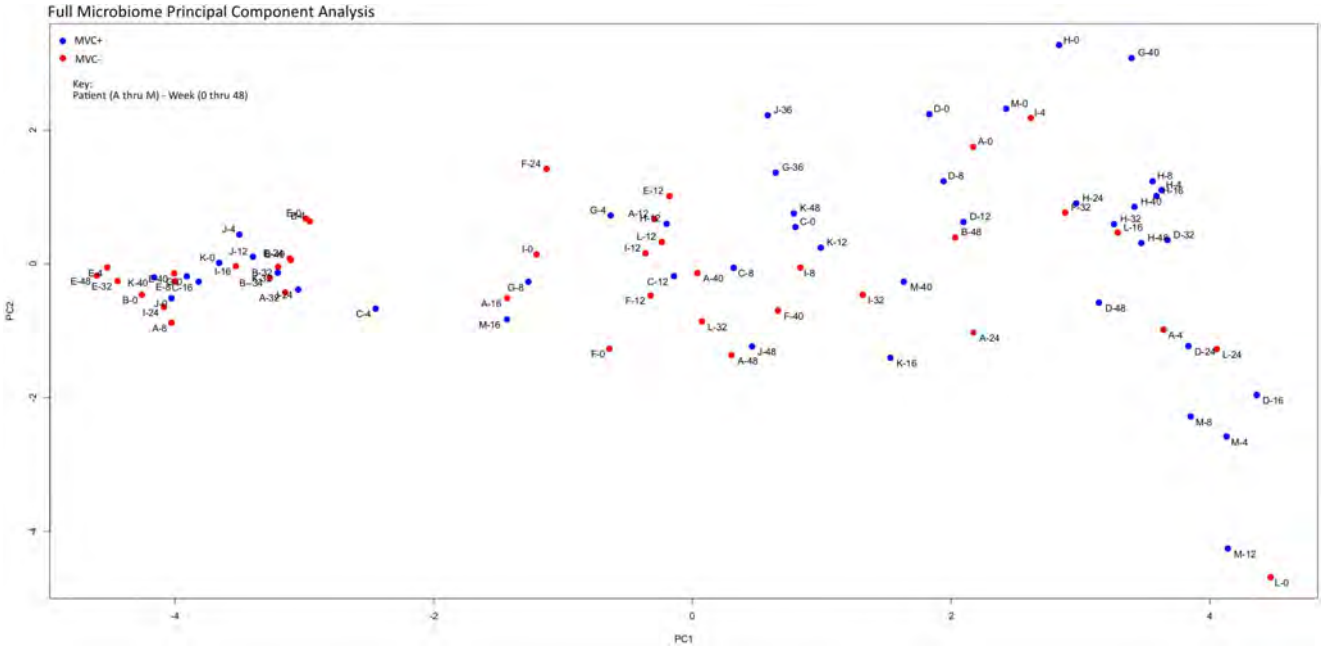
263 Maraviroc Does Not Induce Changes in the Gut Microbiome of HIV-Infected Individuals

Andrej Vitomirov; David M. Smith; Susanna R. Var; Maile Karris; Parris Jordan; Douglas D. Richman; Susan Little; Josué Pérez-Santiago
University of California San Diego, La Jolla, CA, US

Background: HIV preferentially depletes CD4 T cells in the gut-associated lymphoid tissue during acute infection, likely associated with high levels of CCR5 expression. Maraviroc (MVC) blocks HIV entry by binding CCR5. The consequences of MVC treatment on the gut microbiome have not been investigated. Here, we evaluated the impact of antiretroviral treatment (ART) plus MVC intensification on the gut microbiome during primary HIV infection.

Methods: Thirteen recently HIV infected persons in the San Diego Primary Infection Cohort were randomized to receive early ART (atazanvir, ritonavir, tenofovir and emcitritabine) with or without MVC. Anal swabs were collected prior to the start of ART and approximately every 4 weeks thereafter for 48 weeks. Stool DNA was extracted from the swabs and the V6 region of the 16s rDNA gene was pyrosequenced. We classified bacterial sequences at the order level and evaluated microbiome profile differences cross-sectionally and longitudinally between persons who did (MVC+) or did not (MVC-) receive MVC. All analyses were performed with R statistical software.

Results: We classified 13 orders of bacteria that were shared among all participants at baseline. We then compared each order of bacteria between MVC+ (n=6) and MVC- (n=7) individuals at weeks 4, 24, and 48 after initiation of ART. The distribution of bacterial orders between groups did not differ statistically (p>0.05) at any time point (Mann-Whitney test). In a paired analysis comparing baseline bacterial levels with weeks 4, 24, and 48 between MVC groups, we found no differences in the levels of each order of bacteria (Wilcoxon test); however, there was a trend for a reduction of the order of Actinomycetales from baseline to week 48 (p=0.06). When we evaluated the full microbiome of all participants at all time points measured using principal component analysis, there were no clusters based on MVC intensification (see figure).



Principal component analysis of the gut microbiome of patient samples obtained at each timepoint. Each dot, labeled with a letter followed by a number, corresponds to a single sample in which each letter (A through M) corresponds to a patient and the number (0 through 48) identifies at which week the sample was taken. Red points belong to the MVC- group and blue points belong to the MVC+ group. There is no evidence of clusting by MVC group.

Conclusions: In early HIV infection, CCR5 blockade with MVC may be a potent antiviral strategy for reducing the depletion of CD4 lymphocytes in the gut but, it does not significantly alter the gut microbiome. As such, Maraviroc may be a beneficial addition to treatment strategies involving reshaping the gut microbiome.

264 Fecal Microbiota of HIV Controllers Is Similar to That of Non–HIV-Infected Individuals

Selma N. Alva Hernández; Sandra M. Pinto Cardoso; Norma Téllez; Akio Murakami-Ogasawara; Gustavo Reyes-Terán

National Institute of Respiratory Diseases, Research Center in Infectious Diseases, Mexico City, Mexico

Background: Less than 5% of the HIV-infected population is able to control HIV infection in the absence of antiretroviral therapy (ART). This population is commonly defined as HIV controllers (HIC). Studying this population represents a unique opportunity to understand the mechanisms responsible for HIV control. The aim of this study was to address whether HIC have the same alterations in the composition of their gut microbiota as described in chronic HIV infected individuals naïve to ART (CI).

Methods: All participants gave written informed consent. DNA was extracted from stool samples collected from 20 CI, 6 HIC (as defined by viral loads below of 2,000 copies of RNA/mL) and 9 non-HIV-infected individuals (NI). The V3 region of the 16S rRNA gene was PCR amplified and sequenced using a semiconductor sequencer. After quality filtering, taxonomic assignment and alpha diversity (rarefied at 49,208 sequences/sample) were computed using QIIME 1.8.0. Comparisons between groups were performed using Mann-Whitney U-test and Kruskal-Wallis test (GraphPad Prism 5).

Results: Median CD4 counts were 436 cells/mm^3 (237-821) and 947 cells/mm^3 (482-1,160) for CI and HIC respectively; p=0.002. Median plasma viral loads were 74,408 copies of RNA/mL (3,462-2,030,199) and 62 copies of RNA/mL (<40-447) for CI and HIC respectively; p=0.0003. As previously reported, we found lower microbiota diversity in CI than in NI (1,195 ± SD 487 vs 1,652 ± 296, p=0.040). Interestingly, no differences in microbiota diversity were observed between HIC and NI (1,472 ± 655 vs 1,652 ± 296, p=0.689). We found three predominant phyla: *Bacteroidetes*, *Firmicutes* and *Proteobacteria* with an overall median relative abundance of 83.9% ± 17.7%, 11.9 ± 11.6% and 2.0% ± 11.0%, respectively. No significant overall differences were observed at phylum level (p=0.442, 0.479 and 0.555, respectively). However, at family level, we found a significantly lower abundance of both Ruminococcaceae and Lachnospiraceae in CI when compared to NI (p=0.028 and 0.008, respectively). At genus level, no significant differences were found between *Prevotella* and *Bacteroides*, the two most abundant genera belonging to the phylum *Bacteroidetes*, and reported altered in CI (p=0.335 and 0.536, respectively).

Conclusions: HIV controllers do not have significant alterations in gut microbiota composition, previously reported in chronic HIV infected individuals naïve to ART. The fecal microbiota of HIV controllers resembles that of non-HIV-infected individuals.

265 Impact of 2 Antiretroviral Regimens on Fecal Microbial Diversity and Composition

Sandra M. Pinto Cardoso; Selma N. Alva Hernández; Norma Téllez; Akio Murakami-Ogasawara; Gustavo Reyes-Terán

National Institute of Respiratory Diseases, Mexico City, Mexico

Background: Reports have shown that microbial composition of individuals on antiretroviral therapy (ART) is different from that of non-HIV-infected individuals. However, the degree to which ART restores the microbial composition remains unclear. The aim of this study was to determine the effect of two types of ART regimens: Efavirenz-based regimen (EFV) and protease inhibitor-based regimen (PI) boosted with either Lopinavir (LPV/r) or Atazanavir (ATV/r) on fecal microbial diversity and composition.

Methods: All individuals gave informed consent. Fecal samples were obtained from 37 HIV-infected individuals: 20 on EFV-based regimen and 17 on a PI-based regimen and 9 non-HIV-infected individuals. The V3 region of the 16S rRNA gene was PCR amplified and sequenced on a semiconductor sequencer. Alpha diversity computation (observed species rarified at 49,208 sequences/sample), operational taxonomic unit (OTU) picking at 97% ID and taxonomy assignment was performed using QIIME 1.8.0. Statistical analysis was performed using two-tailed Mann-Whitney U-test (GraphPad Prism 6).

Results: Median CD4 counts were 457 cells/mm3 (235-1247) and 559 cells/mm3 (240-1177) for individuals on EFV- and PI-based regimen respectively (p=0.174). All individuals on ART had undetectable viral loads. Median duration of ART was 70 months ± SD 33.36. Individuals under EFV- had significantly lower diversity compared to those on PI-based regimen (p=0.0304) and to non-HIV-infected controls (p=0.0030). Microbial communities were profiled and four predominant phyla were found: Bacteroidetes, Firmicutes, Proteobacteria and Fusobacteria. The phylum Fusobacteria was only observed in individuals under EFV-based regimen (overall RA= 3.591% ± SD 9.05%). The relative abundance

(RA) of Bacteroidetes was significantly reduced in individuals receiving EFV- as compared to those receiving PI-based regimen (p=0.0054) and to non-HIV-infected controls (p=0.0175). At the genus level, the RA of Prevotella was significantly reduced (p=0.0415) and the RA of Bacteroides was significantly enriched (p=0.0328) in individuals receiving EFV- compared to PI-based regimen.

Conclusions: Individuals on EFV-based regimen showed an alteration along the Prevotella/Bacteroides gradient, compared to those on a PI-based regimen. Further analyses are required to account for confounding factors. Deciphering the effects of different ARV regimens on gut microbiota composition is of great interest to develop therapies aimed at restoring the latter to a healthy state.

266 Targeting Gut Dysbiosis With Prebiotics and Glutamine in HIV-Infected Subjects

Sergio Serrano-Villar[1]; Jorge Vázquez-Castellanos[2]; Alejandro Vallejo[1]; Sara Ferrando-Martínez[4]; Talía Sainz[3]; Mar Vera[5]; Santiago Moreno[1]; Andrés Moya[2]; María José Gosalbes[2]; Vicente Estrada[6]

[1]University Hospital Ramón y Cajal, Madrid, Spain; [2]FISABIO-Salud Pública, Valencia, Spain; [3]University Hospital La Paz, Madrid, Spain; [4]University Hospital Virgen del Rocío, Sevilla, Spain; [5]Centro Sandoval, Madrid, Spain; [6]University Hospital Clínico San Carlos, Madrid, Spain

Background: Altered interplay between gut mucosa and dysbiotic microbes during treated HIV infection has been linked to chronic immune dysfunction. Studies evaluating the effects of therapies aimed at shaping gut microbiota in HIV-infected subjects are needed.

Methods: In this study, 45 subjects including 12 HIV+ viremic untreated (VU), 24 ART-treated virally suppressed (AT) and 9 HIV- controls (HIV$^-$) were blindly randomized to receive either prebiotics (scGOS/lcFOS) and glutamine or placebo (34/11), during 6 weeks. We performed a comprehensive assessment of changes in fecal microbiota composition using 16S rRNA deep sequencing and measured a number of immunological markers in plasma and PBMC.

Results: VU showed significantly higher bacterial richness (Chao1 and ACE estimators). In contrast, AT displayed the highest compositional heterogeneity (Shanon index). Unifrac distances showed that VU was the group with greatest bacterial dysbiosis, while AT represented an intermediate state between VU and HIV$^-$ (Adonis; all P<0.05). Using linear discriminant analylis effect size (LefSe) the most enriched bacteria in VU and AT patients was *Prevotella*, while *Bacteroides* and butyrate-producers bacteria were depleted.

Patients in the active arm experienced a compositional shift that was not appreciated in the placebo arm (Figure 1). Clustering analyses revealed that among VU and, to a lesser extent, among AT, the intervention shaped bacterial communities towards the HIV-uninfected group. LefSe indicated that in VU and AT *Prevotella* abundance decreased during the intervention. To identify potential microbial targets for interventions, we assessed in the active arm correlations between changes in dysbiotic bacteria and markers of disease progression. After adjusting for multiple comparisons, variations in *Butyrivibrio*, *Desulfovibrio* and *Blautia* strongly correlated with significant improvements of thymic output (sj/β TREC ratio), while changes in *Catenibacterium* and *Eubacterium* strongly correlated with significant declines of activated (%HLA-DR+CD38+) T cells in both VU and AT (all, P<0.05).

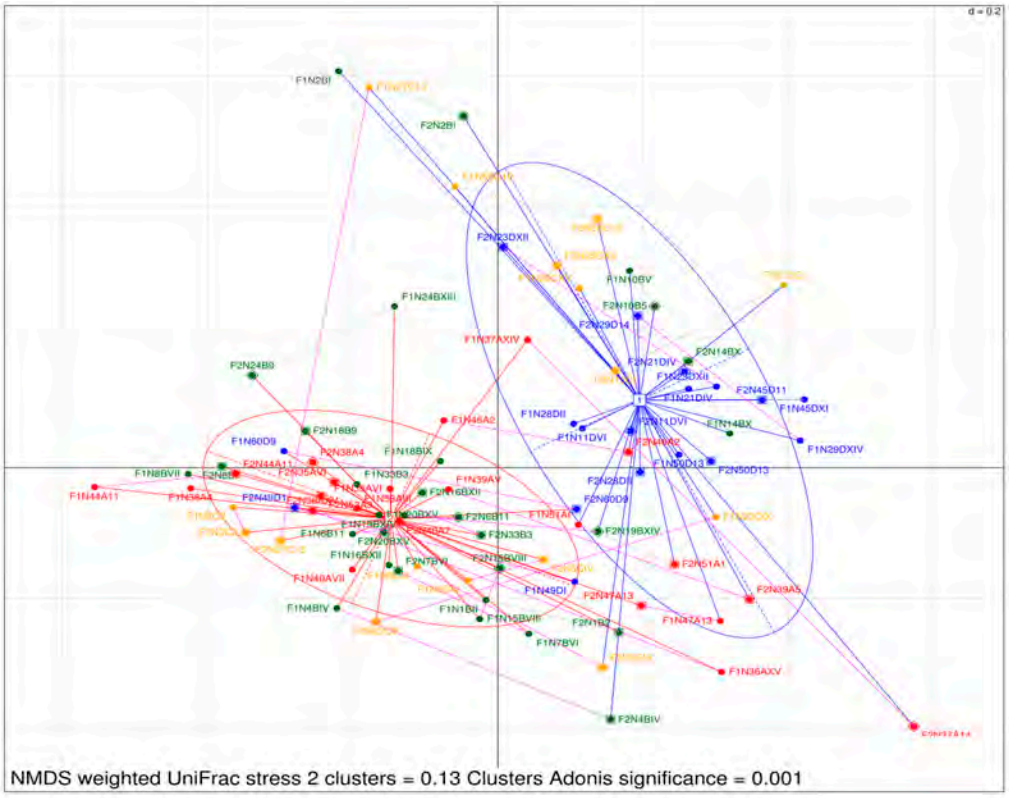


Figure 1. Changes in gut microbiota composition during the intervention.
NMDS of the unifrac distance matrix of the OTU bacterial composition in VU (red dots), AT ≥350CD4/mm3 (green dots), AT <350CD4/mm3 (orange dots) and HIV- (blue dots). The centroids are represented by numbers (1 and 2), while ellipses represent 70% of the samples belonging to each condition. Each point is connected with a dash line to another dot corresponding to the sample at the end of follow/up, purple lines indicates those samples that differs significantly from each other environment. Dots framed by a rectangle represent individuals after treatment with prebiotics and glutamine, dots framed by a diamond represent individuals after treatment with placebo.

Conclusions: A short dietary supplementation with prebiotics and glutamine ameliorated HIV-associated dysbiosis in ART naïve and treated patients, although gut microbiota of treated patients was found more resilient. We identified several bacteria correlated with improvements of markers of immune reconstitution and T cell activation, and hence, potential targets for interventions.

The Mucosa in HIV/SIV Pathogenesis

267 Impact of Mucosal Immunity and HIV Persistence on CD4/CD8 Ratio After ART Initiation

Sergio Serrano-Villar[1]; Talía Sainz[2]; Tae Wook-Chun[3]; Netanya S. Utay[5]; Zhong-Min Ma[4]; Basile Siewe[6]; Steven Deeks[7]; Richard Pollard[4]; Christopher Miller[4]; David Asmuth[4]

[1]University Hospital Ramón y Cajal, Madrid, Spain; [2]University Hospital La Paz, Madrid, Spain; [3]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD, US; [4]University of California Davis, Davis, CA, US; [5]University of Texas, Galveston, TX, US; [6]Rush University Medical Center, Chicago, IL, US; [7]University of California San Francisco, San Francisco, CA, US

Background: The CD4/CD8 ratio correlates with persistent T-cell dysfunction and mortality. We examined the impact of changes (Δ) in the HIV reservoir, systemic inflammation/bacterial translocation and mucosal immunity following ART initiation on CD4/CD8 ratio.

Methods: 33 ART naïve HIV subjects were randomized to efavirenz, maraviroc or maraviroc+raltegravir, each with tenofovir/emtricitabine. Colon and duodenal biopsies were obtained at baseline (BL) and after 9 months of suppressive ART. Duodenal CD4 T-cell density (cells/mm^2) was counted by immunofluorescence antibody (IFA) labeling. Tissue was digested into single-cell suspensions for immunophenotyping. Cell-associated HIV RNA and proviral DNA, lymphocyte subsets and activation phenotypes (CD38$^+$/HLA-DR$^+$) were measured in duodenum, and colon, and in peripheral blood (PB) at BL, month 3, 6, and 9. Plasma IL-6, lipoteichoic acid (LTA), sCD14 and zonulin were measured by ELISA. Associations between ΔCD4/CD8 ratio and variations of continuous variables were analyzed using linear mixed models with random intercepts.

Results: The CD4/CD8 ratio significantly improved during ART in all compartments but recovered less in duodenum (all P<0.001). No difference was observed between the regimens (P=0.102) (Figure 1). Higher PB ΔCD4/CD8 ratio was associated with greater decay of HIV-DNA and HIV-RNA. In PB these correlations were significant for both HIV-RNA and HIV-DNA levels (P<0.001), but only PB ΔCD4/CD8 increments predicted colonic RNA-HIV declines (P=0.001). Increases in CD4/CD8 ratio were related to increased zonulin levels (P=0.076).

Higher CD4/CD8 was consistently associated with a lower % of activated CD8 T-cells in PB (Rho -0.74, P<0.001) and colon (Rho -0.48, P=0.002). PB ΔCD4/CD8 increases predicted comparable declines of T-cell activation in PB and colon (P<0.001) and Δnaïve/memory increases in PB and colon (P<0.001), but not any of these phenotypes of CD4 T-cells in duodenum. A higher PB ΔCD4/CD8 ratio was associated with significant improvements of duodenal CD4-T cells/mm^2, which still remained profoundly impaired at the end of follow-up (mean CD4 cells/mm^2: at baseline, 48, at month 9, 151; in controls: 674; P<0.001).

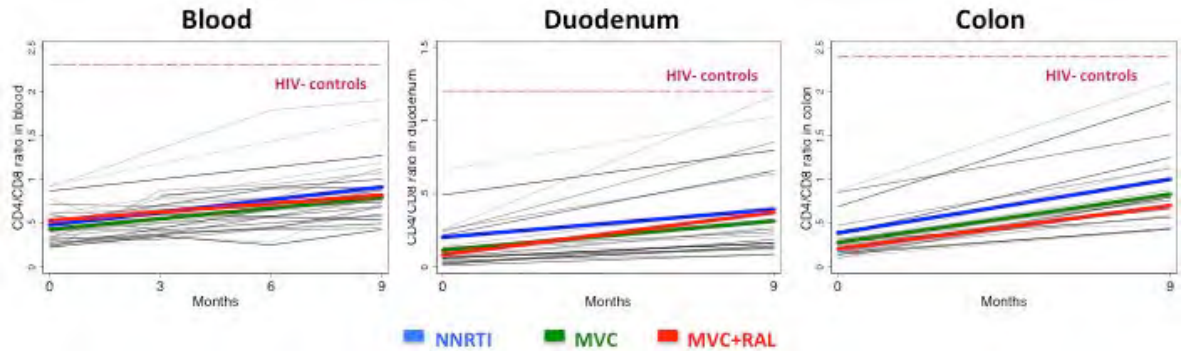

Figure 1. Changes in CD4/CD8 ratio in three compartments during first-line ART. Individual participant trajectories are represented by grey lines. Dash lines represent levels observed in HIV-uninfected individuals. Red, green and blue lines represent mean changes for each treatment arm predicted by linear mixed-effects models adjusted for baseline CD4 counts.

P values for the interaction between treatment arms and time did not reach statistical significance in any compartment.

Conclusions: CD4/CD8 recovery during ART correlates with improvements in markers of viral persistence, T cell activation and T cell maturation in PB and colon. The duodenum may represent a unique compartment for impairment of CD4 maturation and depletion. A quadruple ART regimen did not add detectable benefit to triple ART.

268 Monocyte/Macrophage Activation and Recruitment to Mucosal Sites in SIV Pathogenesis

Jan Kristoff[1]; Jenny Stock[1]; Tianyu He[1]; Bruno Andrade[2]; Benjamin Policicchio[1]; Alan Landay[3]; Ivo Francischetti[2]; Cristian Apetrei[1]; Irini Sereti[2]; **Ivona Pandrea**[1]

[1]University of Pittsburgh, Pittsburgh, PA, US; [2]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD, US; [3]Rush University, Chicago, IL, US

Background: Monocytes/macrophages (Mo/Ma) assume unique functions in HIV infection, being linked to microbial translocation, immune activation and inflammation (IA/INFL). We compared the fate of Mo/Ma in pathogenic, nonpathogenic and controlled SIVsab infection of pigtailed macaque (PTM), African green monkey (AGM) and rhesus macaques (RM) to better define their role in SIV pathogenesis.

Methods: We assessed Mo/Ma subsets (CD14, CD163, CD16), mobilization (CCR5, a4b7, CCR7, CXCR3), IA (CD80, 86, Ki-67, CCR5, TF), apoptosis (Cas-3), cytokine production (IL-6, IL-10, IL-12 and TNF-a), and phagocytic capacity of Mo/Ma in blood, LNs and intestine. We measured soluble Mo activation markers (sCD14, sCD163, sTF). Tissue infiltration of Ma was assessed by HAM56, CD68, CD163, CD16. Ma trafficking in tissues was assessed by administration of iron oxide microparticles.

Results: Increased CCR5 Mo expression correlated with their loss in circulation and increases in the gut in SV-infected PTMs. Increased CCR7 Mo expression was associated with Ma increase in the LNs in AGMs. No significant Mo/Ma variations were observed in RMs. Increased Mo/Ma proliferation occurred at all sites in PTMs, only in LNs in AGMs, and mainly in blood in RMs. Increased CCR5, CD80, CD86 and TF were observed on Mo/Ma from PTMs, while no changes occurred in AGMs. In RMs CD80 only increased in blood, while CD86 was decreased. Increased Mo/Ma apoptosis occurred early in PTMs and RMs, but was absent in AGMs. Phagocytic activity increased in PTMs but not in AGMs or RMs. Mo produced higher amounts of IL-6 and IL-12 in PTMs, IL-10 and 12 in RMs, while inflammatory cytokine did not increase in AGMs. In the gut AGM Ma produced IL-10, while PTM Ma produced IL-6 and TNF in addition to IL-10. RMs Ma did not show increases in cytokine production in the gut. Soluble markers of monocyte activation and sTF increased throughout infection in PTMs, but not AGMs. Massive infiltration with Ma was observed in LNs, gut, liver, lung and heart in chronically-infected PTMs but not in AGMs and RMs. Ma containing microparticles were found in liver, spleen, myocardium and pericardium in progressive hosts.

Conclusions: Progressive SIV infection is associated with increased activation, apoptosis and massive Mo recruitment to mucosal and nonmucosal tissues. These data suggest that Mo/Ma fuel immune activation and inflammation and development of comorbidities that distinguish progressive from nonprogressive SIV infection.

269 Rectal Tenofovir Gel Usage Is Associated With Changes in the Mucosal Proteome

Adam Burgener[1]; Laura Romas[1]; Kenzie Birse[1]; Kenneth H. Mayer[3]; Irma Febo[5]; Ross Cranston[2]; Alex Carbarballo-Dieguez[4]; Ian McGowan[2]

[1]University of Manitoba, Winipeg, Canada; [2]University of Pittsburgh, Pittsburgh, PA, US; [3]Harvard Medical School, Boston, MA, US; [4]Columbia University, New York, NY, US; [5]University of Puerto Rico, San Juan, US

Background: After the success of the CAPRISA-004 clinical trial showing efficacy of vaginally-applied tenofovir (TFV)-based gels at preventing HIV infection, rectal formulations are currently being explored as a prevention option. However, further research is needed to characterize the safety of rectal microbicide gels. Standard mucosal safety tests, such as inflammatory cytokine measurements, may miss important immunological or biological side effects. Advances in systems biology tools, such as mass spectrometry, allow the monitoring of hundreds of mucosal immune factors simultaneously. Here we performed a comprehensive proteomic analysis to explore the impact of tenofovir 1% gel when applied rectally in the Project GEL study (MTN).

Methods: Project GEL was a phase 1 randomized, double-blind, multi-site, placebo- controlled trial in which in which 24 participants were randomized 1:1 to receive rectal tenofovir 1% gel or (HEC) universal placebo gel. Study participants received one dose at first visit under observation, and then after a one-week recovery period, seven consecutive once-daily doses. Rectal mucosal swabs were collected on each visit. Mucosal samples were then analyzed by label-free tandem-mass spectrometry. Data was normalized and log transformed, followed by statistical analysis including paired (time-effects) and unpaired (across study arm) *t*-tests to identify differentially expressed proteins. Only high power (low technical variance) proteins were utilized in downstream analysis.

Results: Over 249 unique proteins were identified in rectal mucosal samples. Within the TFV-arm, 7% (17/249, $p<0.05$) and 10% of total proteins changed (25/249, $p<0.05$) after 1 and 8 daily applications of TFV-gel, respectively, compared to 3% (7/249, $p<0.05$) and 6% (16/249,$p<0.05$) in the HEC arm. Biofunctional analysis utilizing DAVID gene ontology toolset indicated the TFV arm differentially expressed proteins were strongly associated with epidermal development ($p=5.1E-9$) and structural activity functions ($p=1.5E-07$), whereas HEC arm had milder associations with cell activation ($p=4.3E-3$) after 7 days usage.

Conclusions: These preliminary studies suggest that rectal TFV-gel usage may be associated with mucosal proteome changes related to epidermal development. Further long-term studies are warranted for validation of these biomarkers including the impact of TFV-based rectal microbicide gels on the overall mucosal proteome.

270 Links Between Systemic and Mucosal Immunity in Treated HIV Infection

Talía Sainz[1]; Sergio Serrano-Villar[2]; Gregory Melcher[3]; Zhong-Min Ma[3]; Christopher Miller[3]; Netanya S. Utay[4]; Basile Siewe[5]; Paolo Troia-Cancio[3]; Elizabeth Sinclair[6]; David Asmuth[3]

[1]Hospital Universitario Gregorio Marañón, Madrid, Spain; [2]Hospital Ramon y Cajal, Madrid, Spain; [3]University of California Davis, Davis, CA, US; [4]University of Texas Medical Branch, Galveston, TX, US; [5]Rush University Medical Center, Chicago, IL, US; [6]University of California San Francisco (UCSF), San Francisco, CA, US

Background: Recent data suggest that biomarkers of gut epithelial barrier dysfunction, bacterial translocation and inflammation predict mortality and are possibly linked to altered gut immunity. A better understanding of the underlying mechanisms might help to design interventions targetting chronic inflammation.

Methods: We assessed biomarkers of inflammation (IL-6) and gut barrier (lipoteichoic acid [LTA], sCD14 and zonulin) in a clinical trial comparing three different ART initiation regimens on 33 ART naïve HIV+ subjects. Peripheral blood, rectal and duodenal biopsies were obtained at baseline and 9 months after randomization. Immunohistochemistry of biopsies was performed to determine CD4 T cells/mm^2. Tissue was digested into single-cell suspensions for immunophenotyping. Spearman's rank correlation coefficients were assessed at month 9 and associations between changes in continuous variables over time were analyzed using linear mixed models with random intercepts.

Results: In duodenum, T-cell density correlated with plasma markers of gut barrier integrity: for CD4 T-cells and zonulin, Rho 0.59, $P=0.002$; for CD8 T-cells and lipoteichoic acid, Rho 0.67, $P<0.001$.

From maturational subsets, we observed significant correlations between zonulin and naive (CCR7+CD45RA+) CD8-T cells in colon and duodenum (Rho -0.51, $P<0.01$ and Rho -0.58, $P<0.01$) as well as with EM (CCR7+CD45RA-) CD8-T cells in colon and duodenum (Rho -0.58, $P<0.01$ and Rho -0.44, $P<0.01$). The naive/memory CD8 T-cell ratio in colon and duodenum correlated with zonulin levels (Rho 0.52, $P<0.01$and Rho 0.54, $P<0.01$, respectively). Transitional memory (TM) (CCR7-CD45RA-CD27+CD28+) CD4 T cells correlated with IL-6 levels (Rho -0.51, $P<0.01$)

Linear mixed models identified variations of intestinal T cell phenotypes significantly associated with changes of systemic markers: in duodenum, CD4 and CD8-T cells/mm^2, CD8+EM T cells and naive/memory CD8-T cell ratio predicted changes in zonulin levels, while in colon changes of CD4+TM predicted decreases of IL-6.

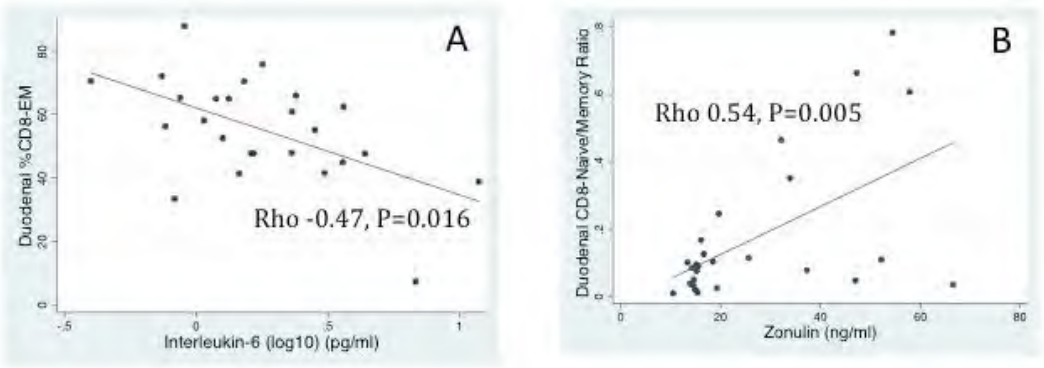

Figure 1. Correlations in treated HIV infected individuals between IL-6 levels and %CD8-Effector Memory cells in duodenum (A) and between zonulin levels and CD8-naive/memory T cell ratio in duodenum (B).

Conclusions: We observed a number of significant correlations between different intestinal T-cell phenotypes and systemic markers of inflammation and gut barrier integrity, suggesting that strategies aimed at modulating chronic inflammation may require targeting the gut immunity and/or gut microbial community composition.

271 No Impact of Early Intensified Antiretroviral Therapy on Gut Immune Reconstitution

Connie J. Kim[1]; Rodney Rousseau[2]; Colin Kovacs[3]; Sanja Huibner[2]; Gabor Kandel[4]; Erika Benko[3]; Kamnoosh Shahabi[2]; Tae Wook Chun[5]; Mario Ostrowski[2]; Rupert Kaul[2]

[1]Toronto General Hospital, Toronto, Canada; [2]University of Toronto, Toronto, Canada; [3]Maple Leaf Medical Clinic, Toronto, Canada; [4]St. Michael's Hospital, Toronto, Canada; [5]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD, US

Background: HIV infection is characterized by reduced mucosal Th22 and Th17 cell numbers and function, which contribute to microbial translocation and inflammation. Standard antiretroviral therapy (ART) is slow to reverse these mucosal defects, and the resulting persistent inflammation is linked to serious non-AIDS illnesses (SNAs). We examined whether ART intensification with maraviroc and raltegravir during very early HIV infection would accelerate the resolution of gut immune dysfunction, microbial translocation, and SNA biomarkers.

Methods: ART-naïve men with early HIV infection were randomized 1:1 in a double-blind manner to receive standard ART (emtricitabine/tenofovir + lopinavir/ritonavir) with either raltegravir (400 mg/day) and maraviroc (150 mg/day), or placebo, for 48 weeks [NCT01154673]. In a predefined substudy, paired blood and sigmoid biopsies were collected from participants at baseline and week 48, and from HIV-uninfected controls. Mucosal CD4 T cell immunology (Th1, Th17 and Th22 cells), and blood markers of microbial translocation (LPS), immune activation (sCD14) and SNA (IL-6 and D-dimer) were assessed.

Results: Twenty-two participants documented to have acquired HIV a median of 4 months ago were enrolled. Prior to ART initiation, gut Th22 cell numbers ($P<0.001$) and Th17 polyfunctionality ($P=0.001$) were reduced compared to controls, and plasma LPS ($P=0.033$) and D-dimer levels ($P=0.020$) were elevated. At 48 weeks after ART initiation, overall gut Th22 cell numbers were restored ($P=1.00$), but plasma LPS levels ($P=0.226$) and gut Th17 function ($P=0.990$) were unchanged, and blood D-dimer levels had actually increased ($P=0.020$). ART intensification had no impact on gut CD4 T cell immune subsets (Th1, Th17 and Th22 cells), microbial translocation (LPS), or SNA biomarkers (D-dimer and IL-6); there was a trend to reduced plasma sCD14 in the intensified arm ($P=0.080$).

Conclusions: Early HIV infection was associated with substantial gut mucosal immune dysfunction, bacterial translocation and systemic inflammation. Regardless of intensification with raltegravir and maraviroc, one year of ART had a limited impact on mucosal immune reconstitution or blood markers of microbial translocation, inflammation, and SNAs.

272 Altered Properties of Mucosal NK Cell Subsets During Acute HIV-1 Infection

Alexandra Schuetz[1]; Yuwadee Phuang-Ngern[1]; Eugene Kroon[1]; Rungsun Rerknimitr[3]; Nitiya Chomchey[2]; Nittaya Phanuphak[2]; Merlin L. Robb[4]; Jerome H. Kim[4]; Mark de Souza[2]; Jintanat Ananworanich[4]
RV254/SEARCH 010 and RV304/SEARCH 013 Study Groups

[1]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand; [2]Thai Red Cross AIDS Research Center, Bangkok, Thailand; [3]Chulalongkorn University, Bangkok, Thailand; [4]US Military HIV Research Program, Silver Spring, MD, US

Background: The role of mucosal innate immunity during acute HIV infection (AHI) is poorly understood, however increasing evidence supports a beneficial role of natural killer (NK) cells. Here, we investigate the distribution and activation of mucosal NK cell subsets during early AHI.

Methods: 27 subjects in Fiebig (F) I (n=11) and FIII (n=16) underwent sigmoid biopsy at the time of AHI diagnosis. Ten gender- and age-matched HIV-uninfected (HIV-) and 5 ART-naïve chronically HIV-infected (CHI) subjects served as controls. Mucosal mononuclear cells were isolated, and NK cell subsets were defined by the expression of $CD56^{(neg, dim, bright)}$ and NKp44 using multi-parameter flow cytometry.

Results: At the time of diagnosis, FI subjects had similar frequencies of total NK cells compared to HIV- and CHI, while FIII subjects showed a significant expansion (Table 1). In contrast surface expression of the activating natural cytotoxicity receptor, NKp44, was significantly increased on total NK cells at FI compared to FIII, HIV- and CHI. $CD56^{dim}$ cytolytic NK cells were the dominant subset of NK cells and were significantly decreased in FI and FIII patients compared to HIV- and CHI. The expression of NKp44 on $CD56^{dim}$ NK cells correlated inversely with plasma HIV RNA ($r=-0.48$, $p=0.01$). However, FI patients showed a significantly higher expression of NKp44 compared to FIII, HIV- and CHI. The frequency of immunoregulatory NK cells ($CD56^{bright}$) also decreased in FI and FIII compared to HIV-, and did not recover during CHI. In contrast, a significant expansion of the $CD56^{neg}$ NK cell subset, associated with chronic viral infection, was observed in FI and FIII compared to HIV- and CHI.

Table 1: Frequencies (%) of NK cell populations.

NK Cell Population	Fiebig I	Fiebig III	HIV-	CHI
total NK	20.3	28.5*	20.9	22.0
total NK NKp44+	9.9	4.4*	5.3*	6.3*
$CD56^{dim}$ NK	65.9	64.5	82.5***	87.1***
$CD56^{dim}$ NK NKp44+	12.1	4.9*	4.4***	2.1**
$CD56^{bright}$ NK	3.4	3.2	6.3*	2.7
$CD56^{neg}$ NK	24.6	26.7	8.9***	8.2***

All data are median (interquartile rang); All comparisons were made to Fiebig I: *p≤0.05, **p≤0.01 and ***p≤0.001

Conclusions: Distribution of mucosal NK cells subsets is altered during early AHI characterized by the loss of cytolytic $CD56^{dim}$ and immunoregulatory $CD56^{bright}$ NK cells and the expansion of $CD56^{neg}$ NK cells, a dysfunctional subset associated with impaired cytotoxicity. The reason for the early loss, without recovery, during CHI of the $CD56^{bright}$ subset warrants further investigation in the pathogenesis of HIV infection.

273 Loss of Cervical Gamma Delta 1 T cells in HIV-Infected Women

Natasa Strbo[1]; Maria L. Alcaide[1]; Laura Romero[1]; Hector Bolivar[1]; Deborah L. Jones[1]; Eckhard R. Podack[1]; Margaret A. Fischl[1]

[1]University of Miami, Miami, FL, US; [2]University of Miami, Miami, FL, US

Background: Human gamma delta (GD) T cells are essential components of the adaptive and innate immune system and play a well-documented role in epithelial barrier protection and tumor surveillance. Two subsets of GD T cells, defined by the use of either the V delta 2 (D2) or V delta 1 (D1) TCR, predominate. The majority of the circulating GD T cells bear V D2 TCR while the majority of the tissue-associated GD T cells are D1.

We hypothesized that, being the major component of intraepithelial mucosal compartment, endocervical GD T cells may have a decisive role in HIV infection and could help to control HIV replication. This study evaluates GD T cells in endocervical samples from women with and without HIV infection.

Methods: HIV infected (n=6) and HIV uninfected (n=7) pre-menopausal women participating in the WIHS cohort were recruited. Participants underwent vaginal examination with collection of endocervical cytobrushes and peripheral blood. Frequency and phenotype of CD3+ T lymphocytes and GD T cells were determined in cervical cytobrush samples and peripheral blood by multicolor flow cytometry.

Results: We found GD2 T cells are predominant GD T subset in the blood of HIV uninfected women (GD2 vs GD1 ratio 2.37±0.90), while we observed significant depletion of GD 2 T cells in the blood of HIV infected women (0.07±0.027). In contrast, only GD1 T cells were readily detected in the endocervical samples in both, HIV infected (GD2 vs GD1 ratio 0.03±0.01) and uninfected women (0.028±0.01). In the HIV infected women, we found significant decrease in the frequency of cervical GD1 T cells compared to HIV uninfected

women (19.78%±7.64 vs 54.29 %±10.05; p=0.02). Interestingly, in the HIV infected women the ratio of alpha beta to gamma delta T cells was significantly increased compared to HIV negative women (3.16±1.45 *vs* 0.42±0.17, p=0.04).

Conclusions: Current knowledge of the immune dynamics at the female reproductive tract is limited at best. We report for the first time, the unique GD1 T cells are a predominant T cell subset within cervical mononuclear cells. By eliminating cervical GD1, HIV cripples an important antiviral effector subset and removes a normal control over inflammation resulting in HIV persistence and progressing disease. We propose that evaluation of GD T cell responses could be used as a novel marker of mucosal vulnerability in women with HIV infection or at risk for HIV.

274 T Regulatory Cells Disrupt the CCL20-CCR6 Axis Driving Th17 Homing to the Gut

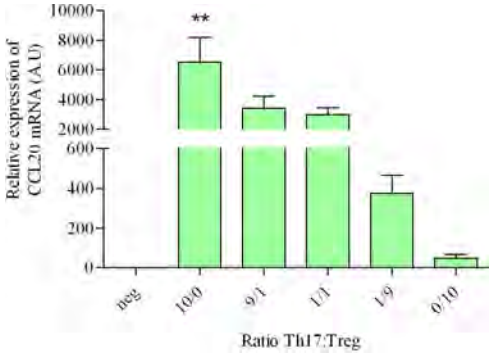
Claire Loiseau[1]; Mary Requena[1]; Michelle Cazabat[1]; Nicolas Carrere[2]; Bertrand Suc[2]; Bruno Marchou[2]; Jacques Izopet[1]; Pierre Delobel[1]
[1]Inserm, Toulouse, France; [2]Centre Hospitalier Universitaire de Toulouse, Toulouse, France

Background: During HIV-1 infection, the integrity of the intestinal immune barrier is disrupted due to a deep depletion of $CD4^+$ T cells in the gut, including Th17 cells, a T cell subset exerting a major role in antimicrobial immunity. The translocation of microbial products from the gut lumen into the bloodstream, associated with Th17 cells loss, has been linked with systemic inflammation. Despite effective cART, $CD4^+$ T cells in the *lamina propria* are incompletely restored in most individuals. The CCL20-CCR6 axis drives Th17 cells trafficking to the gut. We thus assess the factors regulating the expression of CCL20 by the enterocytes, and notably the role of the cytokines produced by Treg and Th17 cells.

Methods: Small bowell biopsies were obtained by endoscopy in 20 HIV-infected individuals. All of them had prolonged suppression of HIV-1 RNA in the plasma <50 copies/mL under cART for about 5 years. Their median level of blood $CD4^+$ T cells was of 668 cells/μL. Ten healthy HIV-1-negative individuals were used as controls. *CCL20* mRNA was quantified by qRT-PCR.

To explore the factors regulating CCL20 expression by the enteroyctes, we developped an *ex-vivo* system of human primary enterocytes (obtained from small bowel surgical resections of HIV-negative individuals) cultured as a tight monolayer on transwells. The effect of IL-17, IL-10, and TGF-β1 on CCL20 expression was assessed. A coculture was done between the enterocytes and various proportions of Th17/Treg cells, sorted from PBMCs on the basis of their $CD4^+CXCR3^-CCR6^+$ and $CD4^+CD127^{low}CD49d^-$ phenotype respectively (StemCell), and activated by PMA/ionomycin. The expression of CCL20 by the enterocytes was evaluated by qRT-PCR and ELISA.

Results: In small bowell biopsies of HIV-infected individuals receiving effective cART, *CCL20* mRNA was significantly reduced compared to healthy controls ($P < 0.05$). *Ex-vivo* on human primary enterocytes, IL-17A increases CCL20 expression whereas both IL-10 and TGF-β1 reduce it. In coculture expriments, CCL20 expression decreases as the Th17/Treg ratio skews from Th17 to Treg cells (Figure 1).



Conclusions: The CCL20-CCR6 axis driving Th17 cells gut homing is altered in HIV-infected individuals despite effective cART. A persistently imbalanced Th17/Treg ratio in the *lamina proria* could contribute to the reduced production of CCL20 by the enterocytes despite an effective cART. A vicious circle could arise between low CCL20 expression and the defective gut-homing of $CD4^+$ T cells, notably Th17 cells.

Innate and Unconventional T-Cell Responses

275 Effect of KIR2D-Mediated Immunity on Clinical Outcome Among CRF01_AE-Infected Thais

Masahiko Mori[1]; Nuanjun Wichukchinda[2]; Reiko Miyahara[1]; Archawin Rojanawiwat[2]; Panita Pathipvanich[3]; Toshiyuki Miura[1]; Michio Yasunami[1]; Koya Ariyoshi[1]; Pathom Sawanpanyalert[2]
[1]Institute of Tropical Medicine, Nagasaki University, Nagasaki City, Japan; [2]Ministry of Public Health, Nonthaburi, Thailand; [3]Day Care Centre, Lampang Hospital, Lampang, Thailand

Background: Class I human leukocyte antigen (HLA) molecule contributes to the immune control of HIV through antigen presentation to both cytotoxic T lymphocytes (CTL) and natural killer cells (NK). CTL contribution to HIV control through antigen presentation by protective HLA alleles, such as HLA-B*57 and HLA-B*27, has been studied well previously. However, reports on the NK cell contribution, with the exception of the protective effect of HLA-Bw4 and its ligand killer immunoglobulin-like receptor (KIR) 3DL1 and 3DS1 in HIV disease, are limited. In particular, studies about HLA-C-KIR2D on HIV control remain sparse.

Methods: 209 HIV-1 CRF01_AE-infected treatment-naïve Thais were recruited, and the effects of HLA-C-KIR2D on clinical outcome were statistically analyzed.

Results: 1) HLA-B*46:01, which worked as an HLA-C1 allele binding the same type of ligands despite being an HLA-B allele, was identified as the most predominant HLA-B allele (29% in the population frequency). 2) In the analysis of the viral set point difference among HLA-C1-positive individuals, subjects with KIR2DL3 had significantly higher set point compared to the subjects without KIR2DL3 (median 4.8 vs 4.2 log copies/ml, p=0.033 by Mann-Whitney U-test). 3) In multivariate analysis, the number of HLA-C1-KIR2DL3 associations (ranging from subjects having no HLA-C1-KIR2DL3 associations to subjects having up to four combinations; the KIR2DL3-positive individuals with HLA-B*46:01

homozygous and HLA-C1 allele homozygous) was identified as a significant viral load predictor (β=0.13, p=0.039 by linear regression model). 4) In longitudinal analysis, higher mortality rate was identified among the subjects with higher number of HLA-C1-KIR2DL3 associations (p=0.002 by log rank test; aHR=2.0, 95% CI 1.3-3.2, p=0.004 by Cox hazard model) (Figure). 5) However, no advantage of HLA-Bw4-KIR3DL1/S1 on clinical outcome was found in this cohort.

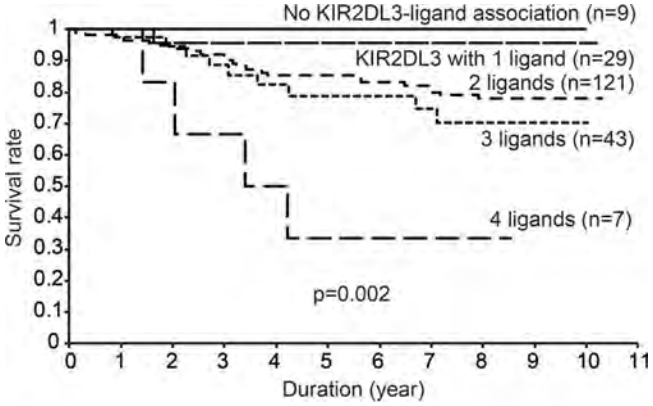

Figure. The number of KIR2DL3-ligand HLA associations and survival rate analysis, log rank test.

Conclusions: In this study, the effects of HLA-C and KIR2D interaction with a focus on the effect of the detrimental HLA-C1-KIR2DL3 association, on clinical outcome among HIV-1 CRF01_AE-infected Thais were investigated. These findings will impact the existence of the unique anti-HIV innate immune pressure and viral adaptation to such pressure in each endemic area.

276 HLA-KIR-Associated Sites in Gag and Their Effects on Clinical Outcome in Thailand

Masahiko Mori[1]; Nuanjun Wichukchinda[2]; Reiko Miyahara[1]; Archawin Rojanawiwat[2]; Panita Pathipvanich[3]; Toshiyuki Miura[1]; Michio Yasunami[1]; Koya Ariyoshi[1]; Pathom Sawanpanyalert[2]

[1]Institute of Tropical Medicine, Nagasaki University, Nagasaki City, Japan; [2]Ministry of Public Health, Nonthaburi, Thailand; [3]Day Care Centre, Lampang Hospital, Lampang, Thailand

Background: Viral peptides (epitope) are presented by class I HLA molecules to both cytotoxic T lymphocyte (CTL) through T cell receptor (TCR), and natural killer (NK) cell through killer immunoglobulin-like receptor (KIR). Compared to the studies about anti-HIV immune pressure by CTL and its related viral adaptation, studies about NK cell remain sparse.

Methods: 208 HIV-1 CRF01_AE-infected treatment naïve Thais were recruited. Their clade I HLA allele, KIR, viral load, and Gag sequence data were collected, and 1) HLA-KIR-associated Gag mutation or preservation sites by Fisher's exact test with 95% confidential interval, 2) effects of HLA-KIR-associated sites on viral load by Mann-Whitney U-test, 3) correlation between the number of associated sites and viral load by Spearman's correlation test, and 4) the number of associated sites and survival rate by log rank test and Cox hazard model, were analyzed.

Results: 1) 52 HLA-KIR-associated sites (20 sites at p17, 15 sites at p24, and 17 sites at p15) were identified, 2) 6 out of 52 sites also scored viral load difference between association positives and negatives with significance; 4 out of 6 sites scored lower viral load among associated mutation positives, suggesting viral escape mutations with lower viral set point by HLA-KIR-derived immune pressure. 3) Negative correlation between the number of mutation at above 4 protective sites and viral load was identified (r=-0.18, p=0.0023). Among 4 sites, 3 sites were HLA-Bw4-KIR3DL1-associated mutations (I104X, N252X, and T454X). Finally in longitudinal analysis, 4) Among HLA-Bw4-KIR3DL1 positives, higher number of HLA-Bw4-KIR3DL1-associated mutations also scored higher survival rate (p=0.0088 by log rank test (Figure), and 0.63 (0.47-0.84) of hazard ratio (95% CI), p=0.002 by Cox hazard model).

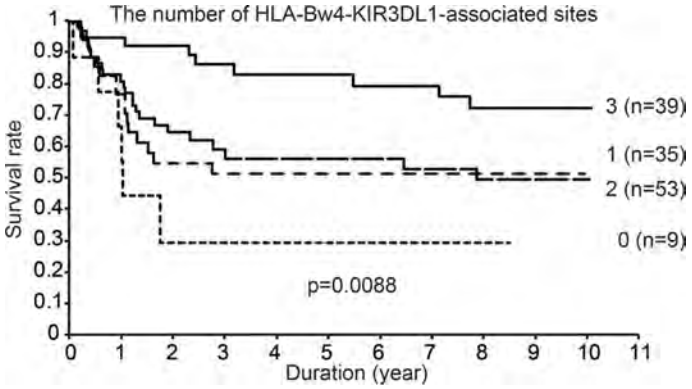

Figure. The number of HLA-Bw4-KIR3DL1-associated sites and survival rate analysis, by log rank test. Survival rate difference among the groups of HLA-Bw4-KIR3DL1-associated sites number (from 0 to 3) are shown. All n=136 subjects are HLA-Bw4+KIR3DL1+.

Conclusions: KIR-HLA-associated sites in Gag were identified, and several sites were strongly associated with clinical outcomes by cross sectional and longitudinal analysis. These findings imply the existence of immune pressure by NK cell and consequent viral adaptation. These findings will contribute to further development of epitope-based vaccine study.

277 In KIR3DL1/S1 Heterozygotes Are KIR3DL1 and KIR3DS1 Co-Dominantly Expressed?

Zahra Kiani[1]; Nicole F. Bernard[1]; Julie Bruneau[2]

[1]McGill University, Montreal, Canada; [2]Centre de Recherche du Centre Hospitalier de l'Universite de Montreal, Montreal, Canada

Background: Epidemiological studies show that co-carriage of *KIR3DS1* (*3DS1*) and a subset of *HLA-Bw4* alleles with an isoleucine at position 80 of the HLA heavy chain (*3DS1+*80I*) is associated with slow time to AIDS. NK cells from *3DS1+*80I* carriers have high anti-HIV activity. There is conflicting information regarding whether NK cells from *KIR3DL1/S1* heterozygotes (htz) exhibit allelic exclusion or co-dominance in terms of expression of the NK cell receptors 3DS1 and KIR3DL1 (3DL1). Monoclonal antibody (mAb) Z27

binds 3DL1 with a high and 3DS1 with a low intensity. Z27 staining cannot distinguish whether Z27^{high} NK cells express 3DL1 only or include NK cells that also express 3DS1. We developed an approach to address this question.

Methods: Peripheral blood mononuclear cells from *3DL1/S1*htz and, as controls, *3DL1* and *3DS1* homozygotes were stained with anti-CD3, anti-CD56 and Z27. CD3^{-}CD56^{+} NK cells were sorted into Z27^{high}, Z27^{dim} and Z27^{neg} sub-populations. RNA was extracted from each subset and cDNA was prepared from RNA. Real-time (RT)-PCR was used to determine the presence or absence of *3DS1* and *3DL1* transcripts in sorted cells.

Results: First, we verified the specificity of *3DS1*, *3DL1* primer sets. We verified that the sorting gates distinguishing Z27^{dim} from Z27^{neg} populations were correctly set by showing that no *3DS1* transcripts were present in the Z27^{neg} subset from either *3DS1*hmz or *3DL1/S1*htz. Using RT- PCR and the *3DS1* specific primers we found that the Z27^{dim} subset of *3DS1*hmz and both the Z27^{dim} and Z27^{high} subsets of *3DL1/S1*htz amplified *3DS1* transcripts. We found *3DL1* primers amplified transcripts from Z27^{high}, but not from the Z27^{dim} subset of *3DL1/S1*htz.

Conclusions: 3DL1 and 3DS1 can be co-dominantly expressed on NK cells. The accepted theoretical paradigm posits that engagement of the inhibitory 3DL1 NK receptor by its ligand, HLA-Bw4, is important in licensing NK cells for function. Engagement of the activating 3DS1 NK receptor should tune down the potency of NK cell licensing and the functional potential of 3DS1+ NK cells. This raises questions regarding the mechanism underlying the association between *3DS1+*80I* carriage and HIV control. Our results provide a framework for improving our understanding of the role played by the 3DL1 and 3DS1 receptors in determining the function of NK cell subsets in general and the anti-HIV function of these cells in particular.

278 Disruption of Innate-Like Unconventional T-Cell Subsets in HIV-Infected Children

Alka Khaitan[1]; Adam Kravietz[1]; Ilmet Tiina[1]; Mussa Mwamzuka[2]; Fatma Marshed[2]; Cihan Tastan[1]; Aabid Ahmed[2]; Bill Borkowsky[1]; Derya Unutmaz[1]
[1]New York University School of Medicine, New York, NY, US; [2]Bomu Hospital, Mombasa, Kenya; [3]New York University School of Medicine, New York, NY, US

Background: A subset of T cells comprised of mucosal associated invariant T (MAIT), natural killer T (NKT), and γδ T cells exhibit features of innate cells such as invariant TCR and recognition of non-peptide antigens. These unconventional T cell subsets can secrete pro-inflammatory cytokines or display cytotoxic activity in response to bacterial and fungal derived glycolipids or metabolites. HIV+ adults have lower MAIT and NKT and higher γδ T cells in the peripheral blood. Less is known about their changes in HIV-infected children. We sought to determine whether innate-like T cells are disrupted in treated and untreated HIV+ children.

Methods: We evaluated peripheral blood samples of 76 perinatally-infected HIV+ and 40 HIV- children between 3-12 years old from Mombasa, Kenya. The HIV+ cohort included 39 ART naïve (ART-) and 37 children on ART (ART+). Cryopreserved PBMCs were thawed and stained with surface antibodies CD3, CD4 and CD8 with Vα7.2 and CD161 (MAIT), γδ TCR, and Vα24Jα18 TCR (NKT) then analyzed by flow cytometry. Plasma sCD14 was measured by ELISA. Statistical analysis was performed on GraphPad Prism with Mann-Whitney or Spearman's correlation tests.

Results: HIV+ children had decreased levels of MAIT in CD8+ T cells (ART- p=0.0156; ART+ p=0.0137), which correlated positively with CD4:CD8 ratios (r=0.37, p=0.0018). ART+ had lower MAIT levels in CD4+ T cells (p=0.0090); both HIV+ groups maintained CD4-CD8- MAIT cell frequencies and MAIT cell numbers in total T cells. Plasma sCD14 levels were higher in HIV+ (p=0.0068). In HIV+ children CD8+ MAIT cells inversely correlated with sCD14 (r= -0.33, p=0.0049). NKT cells were also lower in ART- (p=0.0001) and ART+ (p=0.0140) and correlated with CD4:CD8 (r=0.25, p=0.0417). Conversely, γδ T cells were persistently elevated in HIV+ (ART- p=0.0064; ART+ p<0.0001) and correlated positively with sCD14 (r=0.36, p=0.0025). Interestingly, in HIV+ children γδ T cells negatively correlated with CD8+ MAIT (r= -0.36, p=0.0024) and NKT (r= -0.27, p=0.0063) cells and the ratio of γδT/MAIT cells positively correlated with sCD14 (r=.0.37, p=0.0019).

Conclusions: CD8+ MAIT and NKT cells are relatively lower in HIV+ children despite ART compared to HIV- children. This decline in innate-like T cells worsens with diminished immune status. Loss of MAIT cells from the periphery may reflect migration to mucosal tissues in response to microbial translocation. Increases in γδ T cells may be a compensatory response to decreased MAIT and NKT cells in HIV infected children.

279 HIV-1 Alters Innate Immune Response to BCG, Which Differs From SIV Infected Mangabeys

Melanie Gasper; David Sherman; **Donald Sodora**
Seattle Biomed, Seattle, WA, US

Background: Coinfection with *M. tuberculosis,* as well as other *Mycobacteria,* is a leading cause of morbidity and mortality for HIV-infected patients. Here we set out to understand functional immune responses to an opportunistic pathogen, *M.bovis BCG*, during both pathogenic HIV and non-pathogenic SIV infections (natural SIV host sooty mangabeys). *M. Bovis BCG* is a live-attenuated vaccine strain of Mycobacteria, which has demonstrated opportunistic potential.

Methods: Multiparameter flow cytometry and gene expression analysis, utilizing a Nanostring platform (248 genes), was used to evaluate the ability of monocytes and peripheral blood mononuclear cells (PBMC) to respond to 4 hour *ex vivo* BCG stimulation. KEGG analysis was used to identify pathways altered by changes in gene expression. Uninfected and HIV/SIV infected humans and sooty mangabeys were analyzed.

Results: HIV infection was associated with a reduced percentage of whole blood monocytes producing IL-12 in response to BCG (1.8% compared to 4% in uninfected donors; p=0.02). In contrast, SIV+ mangabeys had a higher percentage of monocytes producing IL-12 and TNF-α in response to BCG compared to uninfected mangabeys, suggesting a maintained immune response. In addition, principal component analysis showed that although both species mounted a robust response to BCG, HIV-infected donors had a unique BCG-induced gene expression profile that distinguished them from uninfected age-matched donors. In contrast, SIV-infection status did not alter the gene expression clustering pattern between SIV+ and SIV- mangabeys. KEGG analysis demonstrated that genes with increased expression at baseline in HIV+ donors were significantly enriched within the NK cell cytotoxicity pathway (hypergeometric test; p=0.007), this difference was not seen between SIVneg and SIV+ mangabeys. Additionally, a statistical interaction between HIV disease status and the response to BCG was found in a number of genes related to NK cell function, including NKp46, IFNg and perforin, suggesting that HIV-infection altered the NK cell response to bacterial stimulation.

Conclusions: Overall, these data provide evidence that innate immune responses (including monocyte IL-12 production and NK cell activity) to the BCG opportunistic pathogen are likely to be critical for resistance to opportunistic infections following lentiviral (HIV/SIV) infection.

280 High-Level Replication Allows SHIVs to Overcome the Macaque Interferon Response

David F. Boyd; Amit Sharma; Julie M. Overbaugh
Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US

Background: SIV/HIV chimeric viruses (SHIVs) encoding HIV-1 envelope (Env) have been studied in macaques as models of HIV-1 infection in humans. Typically, the initial chimeric SHIVs generated *in vitro* replicate poorly in macaques, but a subset has been successfully adapted to replicate in macaques through animal passage. The resulting SHIVs cause persistent infection in macaques that mimics many aspects of pathogenic HIV-1 infection. The SHIV/macaque model is limited because the few pathogenic SHIVs currently in use

require adaptation after infection of macaques and do not represent the diversity of circulating HIV-1 variants. Type-I interferon (IFN) is an innate immune factor that induces multiple host restriction factors that could contribute to poor replication of SHIVs, and the role of IFN in SHIV replication in macaques has not been well defined.

Methods: We examined 8 SHIVs, including 3 representing pathogenic SHIVs adapted for replication in macaques, 1 SHIV encoding culture-adapted HIV-1, and 4 SHIVs encoding HIV-1 Envs representing circulating variants for the ability to replicate in macaque lymphocytes. During a 12-day time course, we measured viral replication kinetics during the logarithmic growth phase and sensitivity to IFN for each SHIV.

Results: We found that the SHIVs tested exhibited a range of replication kinetics and that the mean replication slope of SHIVs encoding Envs adapted in culture or in macaques was significantly greater than that of SHIVs encoding Envs from circulating variants (1.01 vs. 0.74, $p = 0.03$). We also found that replication slope positively correlated with resistance to IFN treatment (Spearman $r = 0.88$, $p = 0.007$). By generating chimeras between a pathogenic SHIV and one derived from a circulating HIV-1 variant, we found that high replication kinetics and resistance to IFN treatment mapped to HIV-1 Env.

Conclusions: The findings of this study indicate that HIV-1 Env is a major viral determinant of high replication kinetics of SHIVs in macaque cells and that replication kinetics play an important role in the ability of SHIVs to overcome the IFN response. SHIVs that have been adapted in macaques exhibit high replication kinetics and resistance to IFN, which may contribute to their ability to establish persistent infection in macaques. These studies suggest the presence of an IFN-induced factor(s) that can be antagonized by Envs that facilitate rapid replication.

281 Elevated IFN-γ in HIV Patients Using a Novel Assay for Adaptive and Innate Immunity

Michelle K. Yong[1]; Paul Cameron[1]; Tim Spelman[2]; Julian Elliott[1]; Christopher Fairley[4]; Jeffrey Boyle[3]; Misato Miyamasu[3]; Sharon R. Lewin[1]

[1]Monash University/Alfred Hospital, Melbourne, Australia; [2]Burnet Institute, Melbourne, Australia; [3]Qiagen, Melbourne, Australia; [4]Melbourne Sexual Health Centre, Melbourne, Australia

Background: HIV infection is characterised by immune activation of both the adaptive and innate immune responses that persists in patients following antiretroviral therapy (ART) and has been associated with poor CD4+ T-cell recovery and serious non-AIDS events (SNAE). The aim of this study was to evaluate adaptive and innate immunity in HIV-infected patients prior to and following ART.

Methods: A cross sectional study of HIV and non-HIV infected individuals were recruited from The Alfred Hospital and the Melbourne Sexual Health Centre (MSHC), Melbourne Australia. HIV-infected patients were either naïve to ART or on suppressive ART for 12 months. Whole blood was assessed using the Quantiferon Monitor (QFM) assay containing 1:1 IU/ml of anti-CD3 (T-cell receptor ligand) and R848 (TLR7 ligand). We also assessed 0.1:0.1 IU/ml of anti-CD3 and R848 (QFM 1:10). Production of IFN-γ levels (IU/mL) was measured in supernatant by ELISA.

Results: We recruited HIV-infected participants (n=79; n=20 naïve to ART and n=59 on suppressive ART; median CD4 of 557 cells/μl (IQR 403-729 cells/μl) and median age of 45 years (IQR 34-55 years) and healthy controls (n=229). HIV-infected participants on ART were older (47 vs 31 years, $p<0.001$) and had a longer duration of HIV infection (12.3 vs 1.4 years, $p=0.004$). IFN-γ production with QFM 1:10 was significantly higher in HIV infected patients compared to healthy controls (median IFN-γ 512 vs 223 IU/ml, $p<0.0001$), and this difference remained whether in participants both on or off ART (median IFN- γ 512 and 593 IU/ml respectively, K-Wallis test of difference $p=0.0004$). IFN-γ production in patients on ART was significantly higher in participants with CD4 >350 cells/μL compared to a CD4<350 cells/μL (561 vs 259 IFN IU/ml $p=0.02$). Patients with CD4 counts <350 had responses similar to healthy controls. IFN-γ production was significantly higher in male HIV-infected patients (median IFN 542 vs 77 IU/ml $p=0.02$). There were no known associations between IFN responses and age ($p=1.0$), viral load ($p=0.56$), nadir CD4 count ($p=0.6$) or duration of HIV infection ($p=0.18$). Using a multivariable analysis with 6 variables, neither CD4 nor sex were independently predictive of IFN-γ production.

Conclusions: Using a high throughput assay which assesses both adaptive and innate immunity, we show marked increases in IFN-γ production in HIV-infected patients both on and off ART. Further research is warranted to determine if changes in Quantiferon Monitor are also associated with SNAEs.

282 TLR8 Regulation of LILRA3 Is Abrogated in HIV Infection and Correlates to CD4 Counts and Virus Loads

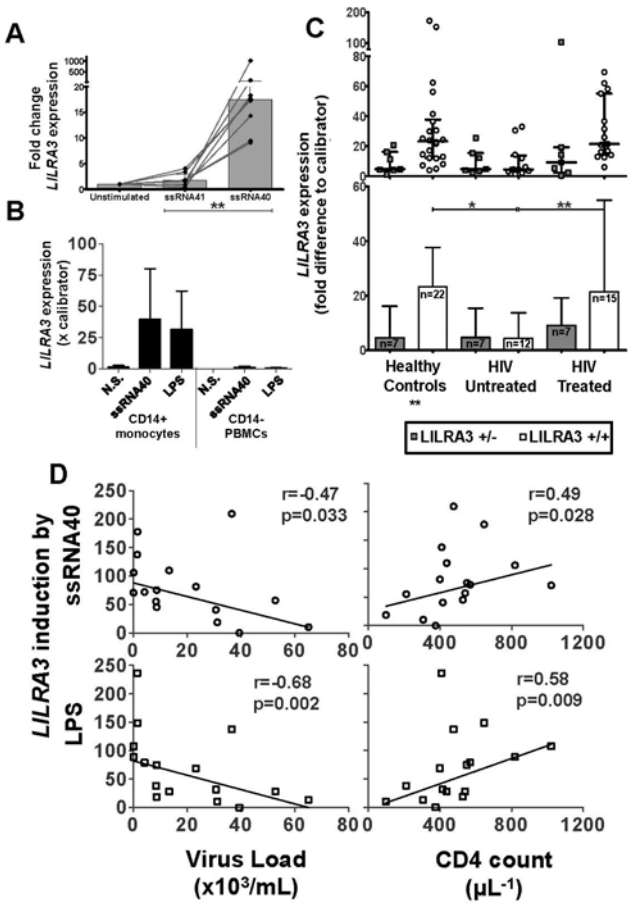
Hui Zhi Low; Gerrit Ahrenstorf; Torsten Witte

Hannover Medical School, Hannover, Germany

Background: LILRA3 is an immunostimulatory molecule which conditionally induces proliferation in CD8+ T-cells and NK-cells via the stimulation of monocytes. LILRA3 has a deletion allele whose presence is a risk factor for HIV. Therefore, we believe that LILRA3 plays a role in viral immunity and want to study how LILRA3 is regulated.

Methods: From a panel of TLR agonists, ssRNA40 is a major inducer of *LILRA3* (not shown). To confirm this, we used ssRNA41 as additional control and studied this regulation in 8 donors. We magnetically isolated $CD14^+$ monocytes after stimulation and analyzed *LILRA3* levels in both $CD14^+$ and $CD14^-$ populations (n=3). Monocytes of healthy donors (n=29), HIV-untreated (n=19) and HIV-treated (n=22) patients were stimulated with ssRNA40 and analyzed for *LILRA3*. Cohorts were segregated according to genotype ($LILRA3^{+/+}$ and $LILRA3^{+/-}$). Mann-Whitney test was used for intra-group *LILRA3* expression. Kruskal-Wallis test was used for inter-group *LILRA3* expression among $LILRA3^{+/+}$. In a second cohort, monocytes of healthy donors (n=13), HIV-untreated (n=16) and HIV-treated (n=11) patients received ssRNA40 or LPS (100 ng/mL). One-tailed Spearman analysis was used to calculate correlation between *LILRA3* expression and virus loads and CD4 counts.

Results: TLR8 agonist ssRNA40 is a potent inducer of *LILRA3* (Figure 1A). This process occurs mainly in monocytes (Figure 1B). By segregation of cohorts into *LILRA3* genotypes, we observed that ssRNA40-induced *LILRA3* is dependent upon its gene dosage, with heterozygotes expressing less *LILRA3* (Figure 1C). Among the $LILRA3^{+/+}$ donors, the TLR8-induced *LILRA3* in HIV untreated patients was abrogated in comparison to the robust responses of healthy controls. LPS induced less *LILRA3* than ssRNA40 among healthy controls (not shown), but remain at similar low levels for HIV untreated patients. We hypothesized that LILRA3 is helpful in controlling virus infections and that ssRNA40 and/or LPS induction of *LILRA3* should correlate negatively to virus load and positively to CD4 counts, and indeed they do in untreated patients (Figure 1D). Finally, LILRA3 itself can induce a host of proinflammatory genes and can alter the antigen presentation machinery of monocytes (not shown).



Conclusions: In conclusion, our experiments supported the beneficial role of LILRA3 in virus infections, in particular for ssRNA viruses, like HIV, that engage TLR8. These findings indicate considerable potential for exploring the use of LILRA3 in the treatment of virus infection.

Monocytes, Dendritic Cells, and Neutrophils

283 Siglec-1 on Monocytes From Untreated HIV-1–Infected Patients Enhances HIV-1 Transfer

Maria Pino; Susana Benet; Itziar Erkizia; Judith Dalmau; Dan Ouchi; Bonaventura Clotet; Javier Martínez-Picado; Nuria Izquierdo-Useros

IrsiCaixa Institute for AIDS Research, Badalona, Spain

Background: The IFNα-inducible receptor Siglec-1 (CD169) is expressed on myeloid cells and recognizes HIV-1 membrane gangliosides, enhancing viral uptake and cell-to-cell transmission. Moreover, Siglec-1 is upregulated on monocytes of HIV-1-infected-individuals with high viral loads. However, if Siglec-1 expressed on monocytes from HIV-1-infected patients mediates viral transmission is still unknown. Here, we aim to study the role of Siglec-1 in HIV-1 transfer on primary monocytes isolated from HIV-1 infected patients.

Methods: We assessed Siglec-1 expression on monocytes from HIV-1-infected individuals before and after antiretroviral treatment and IFNα-treated monocytes from seronegative donors by FACS. $P24^{Gag}$ ELISA and a luciferase-reporter cell line were used to assess monocyte-mediated HIV-1 uptake and transmission. mAb α-Siglec-1 was used to study specific HIV-1 recognition via Siglec-1. Siglec-1 induction was analyzed by FACS on myeloid cells cultured with plasmas from HIV-1-infected individuals, and blocked with the type I IFN recombinant protein B18R. Statistical analyses were performed using paired t-test (*P*) and Pearson correlation (ρ).

Results: IFNα-treated monocytes have an enhanced ability to capture and trans-infect HIV-1 via Siglec-1 recognition. Siglec-1 expression was higher on monocytes isolated before antiretroviral treatment that also exhibited a higher HIV-1 uptake and HIV-1 transmission capacity compared to monocytes obtained under suppressive therapy ($P \leq 0.0117$). Consistently, plasmas of untreated HIV-1-infected individuals triggered higher Siglec-1 expression on myeloid cells compared to plasmas from the same individuals, but obtained after antiretroviral treatment. Furthermore, Siglec-1 induction could be blocked by the neutralizing/decoy type I IFN receptor B18R ($P<0.0001$). Finally, we found a positive correlation between Siglec-1 expression levels on isolated monocytes from treatment-naïve patients and i) HIV-1 uptake ($\rho = 0.8$), ii) HIV-1 trans-infection capacity ($\rho = 0.78$) and iii) plasma viral load ($\rho = 0.66$).

Conclusions: These results indicate that *in vivo*, Siglec-1 expression on peripheral blood monocytes is upregulated by HIV-1 infection, but normalizes after effective antiretroviral treatment. Soluble activation factors from plasma of these patients induced Siglec-1 expression on myeloid cells via type I IFN receptor signaling. Furthermore, Siglec-1 on monocytes enhances HIV-1 cell-to-cell transmission, indicating that this receptor could impact HIV-1 pathogenesis.

284 Soluble CD40 Ligand Contributes to Dendritic Cell Mediated T-Cell Dysfunction

Elizabeth A. Miller; Ramya Gopal; Vanessa Valdes; Jeffrey S. Berger; Nina Bhardwaj; **Meagan O'Brien**
Icahn School of Medicine at Mount Sinai, New York, NY, US

Background: Soluble CD40 ligand (sCD40L) levels are increased during human immunodeficiency virus (HIV) infection, but it is unknown whether monomeric or multimeric forms predominate, and whether there are differential effects of these forms on dendritic cell function and dendritic cell-T cell interactions.

Methods: Immunoblots were performed to delineate various forms of sCD40L present in plasma from HIV-infected donors. Monocyte-derived DCs (moDCs) from seronegative donors were exposed to forms of sCD40L prior to Toll-like receptor (TLR) stimulation and moDC function and T cell function was assessed *in vitro*. Levels of sCD40L in plasma from ART-treated HIV-infected donors before and after low dose aspirin therapy were measured via ELISA.

Results: Multiple forms of sCD40L were identified in plasma from ART-treated HIV-infected donors, including monomers, dimers, and trimers. Though monomeric and multimeric forms of sCD40L had differential effects on DC activation when given alone, both strongly suppressed secretion of the Th1 skewing cytokine, IL-12, upon subsequent TLR stimulation. Furthermore, moDC exposed to both monomeric and multimeric sCD40L induced T cell anergy and regulatory T cell formation. One week of low dose aspirin decreased sCD40L in ART-treated HIV infected subjects, suggesting that heightened sCD40L is due in part to platelet activation and is responsive to anti-platelet therapy.

Conclusions: Elevated sCD40L during HIV infection contributes to dendritic cell mediated T cell dysfunction. Anti-platelet agents that decrease sCD40L may provide immune modulatory benefits as adjunctive therapies to ART.

285 The Alarmin HMGB1 Is Crucial for the Acquisition of Antiviral pDC Effector Functions

Hela Saïdi[1]; Marlène Bras[1]; Pauline Formaglio[1]; Bruno Charbit[1]; Marie-Thérèse Melki[2]; Marie-Lise Gougeon[1]
On behalf of the Antiviral Immunity, Biotherapy and Vaccine Unit
[1]*Institut Pasteur, Paris, France;* [2]*Sebia, Evry, France*

Background: Plasmacytoid dendritic cells (pDCs) are the main producers of interferon-alpha (IFNα), a powerful innate antiviral cytokine. IFNα production by pDCs is promoted by their cross-talk with NK cells, which triggers NK cell-cytotoxicity through the up-regulation of the death ligand TRAIL. HIV-1 directly activates pDCs by inducing their maturation and their production of IFNα. HIV-1 is also involved in the differentiation of pDCs into TRAIL-expressing killer cells. The impact of NK cells on IFN-a-production and TRAIL-expression by pDCs in the context of HIV-1 infection is unknown. Given the essential role of both pDCs and NK cells in the control of HIV-1 infection, the objective of this study was to determine the impact of NK-pDC cross-talk on the reciprocal triggering of antiviral activities.

Methods: pDCs and NK cells were negatively sorted from PBMC of healthy donors. NK cells were kept either unstimulated (rNK) or activated with PMA/ionomycin for 2 hrs (aNK). pDCs were either uninfected or infected with R5-HIV-1 BAL (pDC_{HIV}) at various concentrations and co-cultured with NK cells at different ratios for 24 h. The fate of both cell types was studied using multiparametric flow cytometry combined to Multianalyte Profiling technology and Gene array approach.

Results: HIV-1 infection of primary pDCs induces the expression of maturation markers (HLA-DR, CD80, CD83, CD86) and the homing receptor CCR7. It also induces the emergence of TRAIL-expressing IFNα-producing pDCs in a dose-dependent manner. At low concentrations of HIV-1, the crosstalk of pDC_{HIV} with aNK cells significantly increased the production of IFN-a, the proinflammatory mediators IL-12, TNF-a and IFN-g and the b-chemokines MIP-1 a and MIP-1 b. It also triggered TRAIL expression on NK cells. At high concentrations of HIV-1, NK cells did not significantly modulate the production of these cytokines and chemokines. Interestingly, the alarmin HMGB1 released by pDCs upon HIV-1 infection, plays an essential role during NK-pDC cross-talk, and its inhibition by Glycyrrhizin, N-Ethylpyruvate or anti-HMGB1 Abs prevented pDCs maturation, the release of IFNα and b-chemokines, and the emergence of TRAIL-expressing NK cells and pDCs.

Conclusions: These findings highlight the essential role of NK-pDC_{HIV} cross-talk in the acquisition of effector antiviral functions by pDCs and NK cells and reveal the essential role of HMGB1 during this crosstalk.

286 Dysfunctional Neutrophil Responses to SIV Infection

Tiffany Hensley-McBain[1]; Laura E. Richert-Spuhler[1]; Jillian Gile[1]; Melon T. Nega[2]; Thomas H. Vanderford[2]; Jacob D. Estes[3]; Brandon F. Keele[3]; Nichole R. Klatt[1]
[1]*University of Washington, Seattle, WA, US;* [2]*Emory University, Atlanta, GA, US;* [3]*Frederick National Laboratory for Cancer Research, Frederick, MD, US*

Background: Recent studies indicate that individuals with low neutrophils (PMN) are at increased risk of HIV infection. Also, the RV144 vaccine trial implicated non-neutralizing antibodies and associated Fc-mediated functions in vaccine-induced protection. These studies suggest that early innate antiviral functions and Fc-mediated functions of PMN may play an important role in mediating early viral control, yet the role of innate cellular responses in preventing the establishment of the viral reservoir remains unknown. The potential to contribute to the early control of viral spread may depend on the kinetics of PMN mobilization, activation, and recruitment during acute HIV/SIV infection.

Methods: We assessed kinetic changes in PMNs in peripheral and mucosal tissues during acute SIV infection in six rhesus macaques challenged i.r. with 100,000 TCID50 of SIVmac239X. Flow cytometry, CBC, and luminex were used to assess PMN and cytokine levels and related PMN functional markers. Samples were collected pre-SIV and days 3, 7, 14, 21, 28, 42, and 63 post-SIV.

Results: We observed trending decreases in systemic IL-17 ($p=0.0793$) and G-CSF ($p=0.0625$) early after SIV. In addition, we observed no increase in local IL-8 measured from rectal cytobrush supernatants after infection ($p=0.2751$). Surprisingly, blood PMN concentrations steadily decreased after infection, and no significant increase of PMN was detected in gut or lymphoid tissues. In addition, blood PMN numbers and rectal PMN percentages significantly correlated ($p=0.0032$). Lastly, HLA-DR ($p=0.0313$), CD86 ($p=0.0156$), and FcγRI ($p=0.0313$) were significantly upregulated on PMN during acute SIV infection.

Conclusions: In contrast to other acute viral infections, such as influenza, PMN-supporting cytokines and chemokines are decreased or not induced during acute SIV, potentially contributing to lack of PMN mobilization and recruitment to the tissues. Further, blood and rectum PMN levels correlate post-SIV, suggesting that blood PMN concentration may directly impact recruitment to gut tissues. Lastly, upregulation of markers involved in antigen presentation and Fc-mediated functions highlights the potential diverse functional roles of neutrophils during acute SIV infection and the mechanisms by which neutrophils, if induced, could contribute to more effective viral control. This may represent a mechanism of escape unique to retroviruses by which they dysregulate the cellular innate immune response during acute infection.

Studies of HIV-Exposed Uninfected Individuals

287 HIV-Exposed Seronegative MSM Have Increased Novel Antiviral Factors in Rectal Mucosa

Laura Romas[1]; Klara Hasselrot[2]; Kristina Broliden[2]; Carolina Herrera[3]; Garrett Westmacott[4]; Francis Plummer[4]; Terry B. Ball[4]; Adam Burgener[1]

[1]University of Manitoba, Winnipeg, Canada; [2]Karolinska Institutet, Stockholm, Sweden; [3]Imperial College London, London, United Kingdom; [4]Public Health Agency of Canada, Winnipeg, Canada

Background: HIV-Exposed Seronegative (HESN) individuals have shown altered mucosal immune responses in cervical, salivary and foreskin secretions associated with reduced HIV-susceptibility; however, this has not been investigated in rectal mucosa. As the rectal compartment is a major portal of entry for HIV understanding site-specific immune responses is important for biomedical prevention research. Advances in proteomic tools, such as mass spectrometry, allow for a comprehensive evaluation of several hundreds of immune factors within mucosal secretions. Here we perform the first proteomic analysis of rectal mucosal from HESN MSM identifying unique antiviral factors in this population.

Methods: Rectal lavage from HESN MSM (n=25) and non-exposed healthy controls (n=14) from the Venhälsan clinic, Sweden, were analysed by label-free tandem mass spectrometry. Identification of proteins, differential expression analysis and pathway analysis were performed. Several differentially expressed proteins that demonstrated innate expression were screened for HIV-neutralizing activity in PBMC and colorectal-explant culture and in the presence of R5- and X4-tropic HIV lab strains (HIV-Bal and HIV-3B, respectively) using p24 ELISA.

Results: HESN MSM overexpressed 25 immune proteins, including 3 antiproteases ($p<0.05$). These proteins did not show a significant correlation ($p>0.05$) with clinical variables (frequency oral/anal sex, HIV-neutralizing IgA, and VL of HIV+ partner). Pathway analysis linked overabundant proteins to the canonical pathway. One antiprotease (AP1) overabundant in HESN MSM demonstrated antiviral activity *in vitro*. Preliminary neutralization assays showed that "AP1" reduced Bal infection by a maximum of 61% and reduced IIIB infection by 90% (20 μg/ml) in PBMCs with negligible effect on cell viability (cell viability >60%, $p<0.05$); inhibition of HIV infection in rectal explants inhibited at a maximum of 75% (25 μg/ml).

Conclusions: HESN MSM overexpress an antiprotease with previously undescribed antiviral activity, which may contribute to reduced susceptibility to HIV at the rectal mucosa. This is likely a result of innate differences rather than HIV-exposure. Our findings overlap with previous studies of showing an overabundance of antiviral factors in the cervical secretions of HESN women, supporting further study into their roles in HIV infection. This knowledge is critical for the design of safe, effective HIV-prevention technologies for MSM.

288 PBMC From Highly Exposed Seronegative Individuals Inhibit Transmitted Founder HIV

Kevin C. Olivieri[1]; Eunyoung Kim[3]; Susan Little[5]; Michael Turchin[4]; Vanessa Serrano[1]; Amna Rasheed[2]; Quy Nguyen[1]; Paul Dejesus[1]; Steven Wolinsky[3]; Sumit Chanda[1]

[1]Sanford-Burnham Medical Research Institute, San Diego, CA, US; [2]University of California Los Angeles (UCLA), Los Angeles, CA, US; [3]Northwestern University, Feinberg School of Medicine, Chicago, IL, US; [4]University of Chicago, Chicago, IL, US; [5]University of California San Diego (UCSD), San Diego, CA, US

Background: Highly-exposed Sero-Negative (HESN) individuals engage frequently in unprotected sexual activities, yet remain sero-negative. In order to avoid sero-conversion, these individuals likely restrict HIV infection soon after transmission. Transmission of HIV infection is established by an extremely small fraction of circulating virus. These Transmitted Founder viruses (TFV) likely arise from a single HIV clone. Recently, Parrish and Fenton-May have shown that TFV are type I interferon (IFN)-resistant compared to chronic viruses from the same individual. We hypothesize that HESN inhibit TFV more efficiently than normal donors after IFN-beta treatment.

Methods: We examined the ability of PBMC from 23 normal donors and 32 HESN donors to inhibit 10 TFV or an R5-tropic NL4-3 derivative, JM1186 after IFN-beta treatment in 14 day in vitro assays. p24 concentration was determined by alpha-LISA. HESN PBMC genotypes for selected genes were performed by custom Nimblegen Array and 454 Sequencing.

Results: After low dose IFN treatment, a significant proportion of HESN, but not normal, PBMC inhibited JM1186 infection >25% ($p = 0.0017$). In a separate assay, 12 HESN PBMC and 8 normal PBMC were infected with TF CH040, TF SUMA, TF CH058, 6 month chronic virus (6mo) CH058, and JM1186 and treated or not with 75 IU/ml IFN-beta. In untreated samples, only infection with TF CH058 resulted in a significantly lower p24 in HESN ($p = 0.0473$). Interestingly, this virus does not trigger an IFN response in normal monocyte-derived dendritic cells. In normal PBMC, the TFV CH040 and SUMA were more resistant to IFN-beta than JM1186 ($p = 0.0031$ and 0.0446, respectively). For HESN samples, the median level of IFN-beta inhibition for all viruses was lower than normal, significantly so for CH040 and SUMA, ($p = 0.0027$ and 0.0181, respectively). All samples were ranked for their ability to inhibit all viruses. 6 of 9 HESN donors with ranks above the distribution of normal donors had variations in genes that were reported to interact with HIV Protease, Vpr, Vpu, Integrase, and Env.

Conclusions: PBMC from HESN respond to IFN in a manner that more efficiently inhibits some viruses, including two TFV. HESN appear able to also inhibit an IFN sensitive TFV without IFN treatment. Determining the mechanism of resistance, whether it is increased responsiveness to IFN,expression of variant genes which impede viral replication, or resistance to viral countermeasures, will uncover modes of HIV resistance relevant to in vivo transmission events.

289 HIV-1-Exposed Seronegative Persons Have Lower Mucosal Innate Immune Reactivity

Jennifer A. Fulcher[1]; Jennifer C. Hoffman[1]; Laura M. Romas[2]; Karen Tanner[1]; Terry Saunders[1]; Julie Elliott[1]; Adam D. Burgener[2]; Peter A. Anton[1]; Otto O. Yang[1]

[1]David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA, US; [2]University of Manitoba, Winnipeg, Canada

Background: Mucosal transmission accounts for the majority of HIV infections, yet is a poorly understood event. Risk of HIV acquisition varies, and there are some individuals who appear to remain uninfected despite repeated high-risk sexual exposures, termed HIV-exposed seronegative (HESN). The immunologic factors contributing to this phenomenon are an area of intense interest. It is known that immune activation and inflammation can facilitate HIV disease progression and transmission. Therefore, we hypothesized that altered immune reactivity may contribute to differences in HIV susceptibility. Since innate immunity serves as the initial defense in mucosal HIV exposure, we have focused our studies on characterizing this response in rectal mucosa, a frequent site of HIV transmission.

Methods: Sigmoid biopsies were obtained from healthy control men (N=12) and from HESN subjects (N=4) identified through the MACS cohort. The biopsies were used in an *ex vivo* mucosal explant model and stimulated with select innate immune ligands (TLR ligands, inactivated whole HIV, HSV-2 and Chlamydia) followed by cytokine expression assays, proteomic studies, gene expression analysis, immunohistochemistry, and HIV infection assays.

Results: Gut mucosal explants from all 16 subjects were susceptible to HIV infection, although there was a trend toward lower replication in HESN subjects. Explants from all subjects produced similar amounts of the non-inflammatory cytokines IL-10, IL-4, and IL-5, both at baseline and in response to innate immune stimuli. As expected, control subject explants also produced large amounts of pro-inflammatory cytokines TNF-α, IL-6, and IL-12. In contrast, no HESN subjects produced detectable levels of these pro-inflammatory

cytokines following stimulation. Proteomic analysis similarly identified several immune response proteins to be differentially expressed between HIV-stimulated HESN and control explants.

Conclusions: Mucosal innate immune reactivity is dampened in HESN subjects as evidenced by absence of pro-inflammatory cytokine production following innate immune stimulation. This may contribute to lower target cell availability leading to lower risk of mucosal HIV transmission in these individuals. Ongoing studies to confirm and characterize these findings will further our understanding of the immunologic events determining HIV susceptibility, thereby providing additional avenues for prevention efforts and microbicide design.

290 Increased Levels of Regulatory T-cells Correlate With Protection From HIV Infection

Laura Pattacini[1]; Jared Baeten[2]; Katherine Thomas[2]; **Tayler Fluharty**[1]; Pamela Murnane[2]; Deborah Donnell[2]; Nelly Mugo[2]; Jairam R. Lingappa[2]; Connie Celum[2]; Jennifer Lund[1]

[1]Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, US; [2]University of Washington, Seattle, WA, US

Background: An important challenge related to the development of an HIV vaccine is the lack of known correlates of protection from infection. Individuals who remain seronegative despite repeated HIV exposures (HIV-exposed seronegatives, HESN) offer a relevant model in which to identify correlates of protection. One of the proposed mechanisms of protection from HIV infection is overall immune quiescence, potentially in part due to an increased percentage of regulatory T-cells (Tregs). However, the correlation between Treg frequency and HIV acquisition has not been reported which we investigated in a prospective study of serodiscordant couples.

Methods: Among a cohort of East African subjects highly exposed to HIV as a result of having an HIV-infected partner, we conducted a nested case-control analysis with 142 individuals, who either acquired HIV during follow-up (cases, n=23) or remained HIV uninfected (controls, n=119), selected for highest exposure based on risk score. Samples tested from the cases were the last available peripheral blood mononuclear cells (PBMCs) before the participant became infected. Controls were tested concurrently with cases and those conducting the testing were blinded as to case status. Tregs were identified as CD3+ CD4+ CD25hi CD127lo FoxP3+ cells. Tregs were further characterized by examination of the activation markers CD39, CTLA-4 and ICOS. The frequency of resting and activated Tregs was determined by CD45RA and CD25 expression.

Results: We detected a significantly higher frequency of Tregs in controls, where the average percentage of Tregs among CD3+ T-cells was 3.6%, compared to cases, with 3.1% Tregs (p=0.04). We found no difference in the frequency of resting Tregs (CD45RA+ FoxP3lo), that was 35.2% in controls and 35.0 % in cases (p=0.95) and of activated Tregs, with 4.9% in controls and 5.2% in cases being CD45RA- FoxP3hi (p=0.69). Furthermore, we did not observe any difference in the frequencies of Tregs expressing high levels of the activation markers CD39, CTLA4 and ICOS.

Conclusions: This is the first study to demonstrate a lower Treg frequency in subjects who subsequently seroconverted. Our results support a hypothesis that Tregs could play a protective role against HIV infection.

Host Factors in HIV Pathogenesis

291 Estimating the Respective Contributions of Human and Viral Genetic Variation to HIV Control

István Bartha[1]; Paul J. McLaren[1]; Chanson J. Brumme[2]; Richard Harrigan[2]; Amalio Telenti[3]; Jacques Fellay[1]

[1]École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland; [2]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada; [3]J. Craig Venter Institute, La Jolla, CA, US

Background: Viral load setpoint is a major correlate of HIV disease progression. Genome-wide association studies have identified common human polymorphisms that together explain no more than 15% of its phenotypic variance. Concurrently, studies of the impact of HIV genetic diversity on viral load have produced highly variable estimates. Here we present a joint assessment of the respective contributions of human and viral variation to HIV viral load at setpoint.

Methods: Human genotype data across the Major Histocompatibility Complex (MHC) region, full-length consensus HIV sequences and setpoint viral load results were available for 1034 treatment naïve individuals of European ancestry, infected with HIV-1 subtype B. Heritability (h^2) estimation was carried out with GCTA using three kernel matrices representing: 1) the human Genetic Relatedness Matrix (GRM) derived from the MHC, 2) the viral GRM derived from the full-length sequences, and 3) the sample-specific noise. The human GRM was estimated from 27 common polymorphisms shown to strongly influence viral load selected by LASSO. Bootstrapped phylogenetic trees were inferred from the viral sequences using RAxML. The viral GRM was derived from the phylogenetic trees by taking the branch length of the shared ancestry (i.e. the distance from the root to the most recent common ancestor). The estimates were repeated on 30 bootstrap trees and 15 bootstrap replicates of the samples. Clinical site was included as a covariates in the analyses.

Results: Estimating the host heritability of HIV viral load using the host GRM alone yielded a median estimate of h^2=8% with an interquartile range (IQR) of 1% across 15 bootstrap replicates of the samples. The estimates of the viral heritability drawn from 30 bootstrapped viral trees had a median of 29% (IQR=10%). Combining both the host and viral relatedness matrices showed a comparable viral heritability of 26% (IQR=9%) but a decreased host contribution of 4% (IQR=0%).

Conclusions: This is the first estimate of the combined and respective contributions of the host and the viral genomes to the observed variability of HIV viral load. We showed that both the pathogen and host genomes have detectable impacts on the clinical outcome of infection, which are however not independent. These results suggest that the main predictor of clinical outcome is the viral genotype and that host determination of viral load is largely dependent on its ability to select viral variants.

292 Host Gene Expression Profiles and HIV-1 Infection Outcomes

Romel D. Mackelprang[1]; Ali Filali[2]; Mark Cameron[2]; Rafick P. Sekaly[2]; Elly Katabira[3]; Allan Ronald[4]; Glenda Gray[5]; Connie Celum[1]; M Juliana McElrath[5]; Jairam R. Lingappa[1]

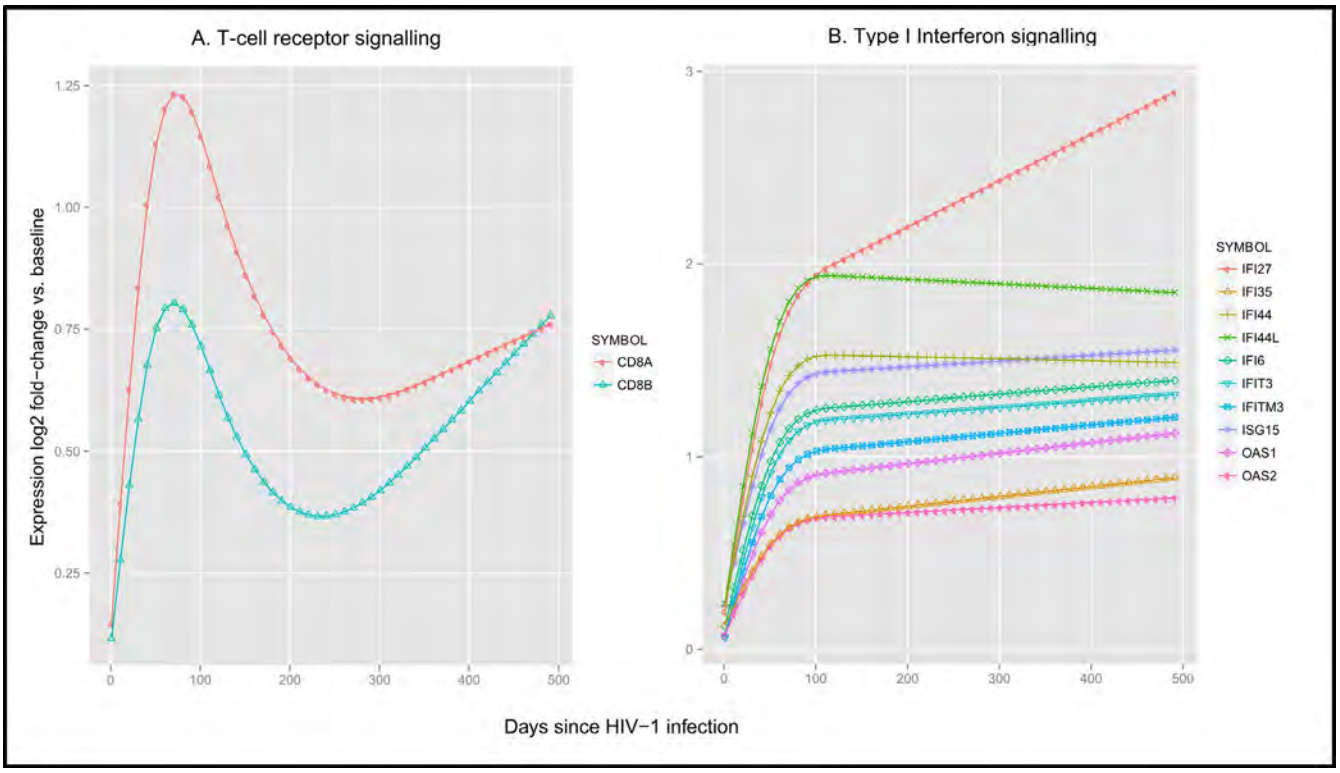
[1]University of Washington, Seattle, WA, US; [2]Case Western Reserve University, Cleveland, OH, US; [3]Makerere University College of Health Sciences, Kampala, Uganda; [4]University of Manitoba, Winnipeg, Canada; [5]Fred Hutchinson Cancer Research Center, Seattle, WA, US

Background: HIV-1 infection elicits host gene expression changes that may impact clinical outcomes. Non-human primate studies suggest that early and persistent expression of interferon-stimulated genes differentiate poor outcomes of SIV infection in rhesus macaques from less severe outcomes in sooty mangabeys. We assessed host gene expression in African HIV-1 seroconverters before HIV-1 acquisition through chronic infection to determine if early changes in gene expression associate with subsequent HIV-1 plasma RNA levels and CD4/CD8 ratios.

Methods: Genome-wide gene expression microarrays were performed on 78 whole blood samples from 17 African HIV-1 seroconverters, including 14 pre and 64 post-infection samples (up to 450 days post-infection) collected from HIV-1 serodiscordant heterosexual couples. For each gene, we evaluated expression changes relative to pre-infection

levels using cubic spline linear models to flexibly fit the relationship between expression and time. We used linear regression to determine associations between gene expression changes <90 days after infection with HIV-1 RNA set point and CD4/CD8 ratios >1 year after infection. Ingenuity pathway analysis identified gene sets. P-values were adjusted for multiple testing by controlling the false discovery rate (FDR).

Results: Expression of 1808 genes changed after HIV-1 infection (FDR<5%). Of these, the maximum expected fold-change during follow-up was 1.4-2 for 408 genes, and >2 for 35 genes. Within 90 days after HIV-1 infection, expression of 7 genes involved in T-cell receptor signaling (e.g. CD8a and CD8b) increased nearly 2-fold versus pre-infection levels before subsequently declining (p=0.03)(Figure 1a). Expression of 28 genes involved in the Type I interferon (IFN) pathway (e.g., IFI27, IFI44, MX1, Tetherin, OAS1/2) increased rapidly <90 days after infection and remained elevated throughout follow-up ($p=9.7x10^{-10}$,FDR<5%)(Figure 1b). IFI27 expression increased most with a 4-fold increase by 90 days after infection (p=0.0007,FDR=2%). Increased expression of genes in the Type I IFN pathway <90 days after infection was associated with increased CD4/CD8 ratios ($p=2x10^{-7}$,FDR<5%), but not HIV-1 set point.



Temporal trajectories of representative genes involved in T-cell receptor signaling (A) and Type I inferferon responses (B). Trajectories were determined using cubic spline linear models to allow flexible relationships between time since HIV-1 infection and gene expression changes. Post-infection gene expression values were evaluated relative to pre-infection values to allow analysis of within-person changes in gene expression.

Conclusions: Similar to rhesus macaques, Type I IFN stimulated genes are persistently expressed during early HIV-1 infection. Expression of these genes is associated with CD4/CD8 ratio but not HIV-1 set point. Further research is needed to identify mechanisms for how ISG expression may alter clinical outcomes.

293 Refinement of Association Signals Assessment of Residual Heritability in Host Control of HIV Viral Load

Paul J. McLaren; **Istvan Bartha**; Jacques Fellay
École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland

Background: Genome-wide association studies of HIV outcome consistently identify the MHC region as the major genetic influence on disease progression. Through establishment of the International Collaboration for the Genomics of HIV we sought to bring together all existing GWAS data in HIV patients to maximize power to uncover further association signals.

Methods: Genome-wide SNP data were collected from 25 clinical centers. Plasma viral load measurements obtained during the chronic phase of untreated infection were available for 6,315 individuals of European ancestry. Missing genotypes were imputed using the 1,000 Genomes Project reference. Single marker association testing was performed per study using linear regression and combined across studies by meta-analysis. Classical HLA alleles and amino acid variants were imputed using the SNP2HLA pipeline. Heritability estimates were calculated using GCTA.

Results: Consistent with previous studies, the top association signal was amino acid position 97 in HLA-B (p=4e-143), with independent associations at positions 67 (p=4e-112) and 45 (p=8e-49) in HLA-B and positions 77 (p=2e-12) and 95 (p=4e-5) in HLA-A. All 5 amino acid positions are located in the peptide-binding groove. Controlling for these positions fully accounted for classical class I HLA allele associations. Independent of the MHC, a second peak of association in the CCR5 region (top SNP rs4317138 p=8e-19) was observed. Conditioning out the known effect of CCR5Δ32, 57 SNPs remained associated at genome-wide significance (p<5e-8) suggesting multiple additional causal variants in this region. Considering all SNPs and assuming an additive genetic model, we obtained a narrow-sense heritability (h2) estimate of 26% (p<2e-16) for viral load. Removing the HLA and CCR5 regions, we observed a reduced, yet still significant h2 estimate of 16% (p=5e-8).

Conclusions: By combining available GWAS data in HIV infected individuals we refined the known association signals in HLA class I and CCR5. Controlling for these main effects, we uncovered additional, independent associations in known regions. Heritability analysis suggested that variation outside known regions, captured through common SNPs, also contribute to HIV control.

294 Genetic and Clinical Predictors of CD4 Recovery During Suppressive cART: WIHS

Ruth M. Greenblatt[1]; Kord Kober[1]; Peter Bacchetti[1]; Ross Boylan[1]; Kathryn Anastos[2]; Mardge Cohen[5]; Mary A. Young[3]; Deborah Gustafson[4]; Bradley Aouizerat[1]
On behalf of the WIHS

[1]University of California San Francisco, San Francisco, CA, US; [2]Montefiore Medical Center, University Hospital for Albert Einstein College of Medicine, New York, NY, US; [3]Georgetown University, Washington, DC, US; [4]State University of New York, Downstate, Brooklyn, NY, US; [5]CORE Center, Chicago, IL, US; [6]National Institutes of Health (NIH), Bethesda, MD, US

Background: Blood CD4 cell counts fail to recover in a significant minority of virologically suppressed cART recipients. We hypothesized that host genetics, including novel mutations, and key clinical characteristics would predict rapid versus slow recovery in women with HIV RNA levels below detection during cART.

Methods: Longitudinal treatment response and clinical data were generated by the WIHS cohort, and used to define rapid vs. slow CD4 cell recovery among women during, at a minimum, the first 2.5 years of cART with virologic suppression. Whole exome sequencing (WES) was conducted on 95 women, with the most consistently slow (n=47) or rapid (n=48) CD4 recoveries. Additive stepwise logistic regression identified statistically significant predictors of rapid recovery.

Results: Each decade increase in age at the start of viral suppression while on cART reduced the odds ratio (OR) of rapid recovery by 0.50 (95% CI 0.27-0.92). Self-reported adherence ≥95% increased the OR of rapid recovery by 2.7 (CI 1.04-7.0). When added as a third predictor, higher CD4 nadir approached statistical significance (OR 1.34 per 100 cells, CI 0.96-1.87). Following WES analysis, rapid CD4 recovery was statistically significantly associated with sequence anomalies aggregated at the gene level for 68 genes (all p<0.001). Notably, the host genes identified were enriched for genes (n=14; 20.6%) that encode for proteins that interact with HIV-encoded proteins. An additional 38 genes (55.9%) encode for proteins that in turn interact with other host proteins known to interact with HIV-encoded proteins.

Conclusions: Despite consistent viral loads below detection on cART, self-reported nonadherence and higher age adversely influenced CD4 recovery. The finding that nonadherence and polymorphisms of HIV target genes influence CD4 recovery suggest that intermittent or low grade viral replication contributed to slow CD4 response in this sample of cART recipients with ≥2.5 years of virologic suppression.

295 Host Genetic Predictors of Plasma Kynurenine/Tryptophan Among Treated HIV+ Ugandans

Sulggi A. Lee[1]; Joel Mefford[1]; Yong Huang[1]; John S. Witte[1]; Jeffrey Martin[1]; David R. Bangsberg[2]; Taisei Mushiroda[3]; Michiaki Kubo[3]; Deanna Kroetz[1]; Peter W. Hunt[1]

[1]University of California San Francisco, San Francisco, CA, US; [2]Massachusetts General Hospital and Harvard University, Boston, MA, US; [3]RIKEN Center for Genomic Medicine, Wako, Japan

Background: Indoleamine 2,3-dioxygenase-1 (IDO) activity, as assessed by plasma kynurenine/tryptophan (KT) ratio, is induced by immune activation and microbial translocation, causes T cell proliferative defects and Th17 depletion, and strongly predicts mortality in treated HIV infection. Whether host genetic variation contributes to IDO activity is unknown.

Methods: We assessed common genetic polymorphisms in association with plasma KT ratio in HIV-infected Ugandans in the UARTO and ARKS cohorts at months 6 and 12 of confirmed antiretroviral therapy (ART)-mediated viral suppression using genome (Illumina OmniExpress) and exome (Affymetrix Axiom) array genotyping. Linear mixed models adjusted for cohort, gender, pregnancy status, and population ancestry were employed for candidate gene and discovery-based analyses. Genome-wide imputation was performed using the 1000 Genomes reference panel. For the candidate gene analysis, genes encoding known factors that induce IDO were included.

Results: Participants (N=597) were mostly female (62%) with a median age of 35, and had advanced disease (median pre-ART CD4+ count 135 cells/mm^3 and HIV RNA 5.1 $\log_{10}$copies/mL). For the candidate gene analysis, single nucleotide polymorphisms (SNPs) in *TNF* (rs17200810[a], rs34451538, rs114064880, rs11575838), *IFNGR1* (rs276565[a]), and *TLR4* (rs2770148[b]) genes were significant at Bonferroni *P* <5E10-5. For the GWAS analysis, one intergenic SNP (between *CSPG5* and *ELP6*) achieved genomewide significance (rs56185965, *P*=8.7E-09), while several other SNPs achieved near-genomewide significance at *P* <5E10-7, including genes encoding 2 different protein tyrosine phosphatases involved in reversible phosphorylation during cell signaling, *PTPRM* (rs75257475[b], rs115059620) and *PTPRN2* (rs6950107), as well as a SNP downstream of *CYP24A1* (rs13041834[b]), which encodes an enzyme that plays a major role in vitamin D metabolism and lies in an H3K27Ac histone mark-enriched region.

Conclusions: Our candidate gene analysis suggests that host genetic variation may modify the impact of IFN-g, TNF-a, and microbial products (via toll-like receptor 4) on IDO induction. The GWAS analysis also identified potential novel mechanisms by which host genetics may modify IDO induction via protein tyrosine phosphatase or vitamin D pathways. Additional studies are needed to confirm these findings in other populations and to validate their functional impact on IDO induction.

[a] Genotyped SNP; [b] In linkage disequilibrium (LD) with a genotyped SNP

296 Regulation of IL-32 Expression by a Promoter Polymorphism and MicroRNA29b in HIV-1 Patients

Carolina Scagnolari; Giulia Cacciotti; Carla Selvaggi; Noemi Giustini; Ivano Mezzaroma; Massimo Gentile; Gabriella D'Ettorre; Ombretta Turrziani; Vincenzo Vullo; Guido Antonelli

Sapienza University of Rome, Rome, Italy

Background: Interleukin-32 (IL-32) is a multi-isoform cytokine that has recently received growing attention as a key component in the antiviral immune response to HIV-1 infection. We previously demonstrated that IL-32 isoforms are highly expressed during HIV-1 infection and that it is associated with low levels of viremia and can increase the expression of well-established type I IFN induced mixovirus resistance proteins A (MxA). Now, we evaluated whether changes in miRNA-29b levels, which has been shown to target the IL-32 mRNA 3'-untranslated region, and a promoter polymorphism in the IL-32 gene, influence IL-32 isoforms and indirectly MxA expression in untreated HIV-1 infected patients

Methods: PBMC samples from 104 untreated HIV-1 infected patients (male/female 82/22; median age: 40 years; median viral load: 46580 HIV-RNA copies/ml and median CD4+T cell count: 355 cells/mm^3) were collected at the Sapienza University Hospital (Rome, Italy). Levels of IL-32 isoforms (α and nonα) mRNA, MxA-mRNA, microRNA29b and rs28372698 (T/A) IL-32 promoter single nucleotide polymorphisms (SNPs) were evaluated by using distinct TaqMan *assays*.

Results: The IL-32 rs28372698 (T/A) genotype frequency was TT (26 %), AT (53%) and AA (21%) among untreated HIV-1 infected patients. We found that patients carrying AA IL-32 genotype have higher expression of IL-32 isoforms (α and nonα) and MxA than those with AT or TT IL-32 genotypes concomitantly with a twofold decrease on HIV-1 viral load. No differences in terms of CD4+ T cell counts were recorded among HIV-1 infected patients carrying different IL-32 genotypes. Furthermore, an inverse correlation between miR-29b and IL-32nonα levels was observed in HIV positive patients ($p<0.05$; r=-0.27) while no significant correlation was found with IL-32α levels. Lastly we found that a strong positive correlation between IL-32nonα and MxA transcript levels exists (p<0.001; r=0.58) and that patients expressing higher levels of miR-29b showed lower levels of MxA (p<0.01; r=-0.41).

Conclusions: Our results indicate that the expression of anti HIV-1 IL-32 isoforms are influenced both by the presence of IL32 promoter polymorphism and levels of miRNA-29b, highlighting the importance of host genetic factors and cellular microRNA in the regulation of IL-32 during HIV-1 patients.

297 LILRA3 Deletion Is a Genetic Risk Factor of HIV Infection

Gerrit Ahrenstorf[1]; Hui Zhi Low[1]; Katja kniesch[1]; Matthias Stoll[1]; Dirk Meyer-Olson[1]; Torsten Matthias[2]; Reinhold E. Schmidt[1]; Torsten Witte[1]

[1]Hannover Medical School, Hannover, Germany; [2]AESKU Diagnostics, Wendelsheim, Germany

Background: Both the risk of transmission of HIV and the clinical course of the disease are influenced by viral pathogenicity as well as host factors. LILRA3 a protein of the leukocyte immunoglobulin-like receptor family exerts various immunmodulatory functions. A naturally occuring 6.7 kbp deletion in the gene locus of LILRA3 results in a null allele and an absence of the protein. The influence of LILRA3 and of the genetic LILRA3 deletion on the transmission and the clinical course of HIV infection was analyzed in this study.

Methods: LILRA3 genotypes were determined by polymerase chain reaction. HIV infected patients that were followed for at least 24 months were categorized into short-term progressors, normal progressors and long-term non-progressors according to the clinical and immunological course. Studies of LILRA3 gene regulation and protein concentrations were performed using real-time PCR, intracellular flow cytometry and ELISA.

Results: The prevalence of homozygous LILRA3 deletion was significantly higher in HIV positive individuals (n= 415) than in controls (n= 615) (p= 0.02). The progression of the disease was faster in patients with homozygous LILRA3 deletion with a higher proportion of short-term progressors among homozygously deleted patients than in heterozygous (p= 0.03) and in homozygously positive (p=0.002) individuals. The relative risk for a faster progression was 1.5 times higher in heterozygous individuals and 3 times in homozygously LILRA3 negative individuals when compared to homozygously positive ones. Functional analysis revealed an upregulation of the LILRA3 gene in Real-time PCR in treated HIV patients when compared to untreated patients (p= 0.007) and controls (p= 0.02) resulting in a higher LILRA3 expression in $CD4^+$ (p= 0.008) and $CD14^+$ (p= 0.02) cells of untreated patients than in controls in intracellular flow cytometry. LILRA3 concentrations in the sera were similar between the groups, in untreated patients a correlation between viral load and LILRA3 concentration was found.

Conclusions: The homozygous LILRA3 deletion is associated with a higher susceptibility for HIV disease and with a faster disease progression in HIV infected individuals.

298LB SIV Infection Triggers Endothelial Dysfunction and Diminished Expression of Krüppel-Like Factor 2 (KLF2) in Nonhuman Primates

Soumya Panigrahi[1]; Michael L. Freeman[1]; joseph C. mudd[4]; Nicholas Funderburg[2]; Scott Sieg[1]; David A. Zidar[1]; Mirko Paiardini[3]; Francois Villinger[3]; Mukesh K. Jain[1]; michael lederman[1]

[1]Case Western Reserve University/University Hospitals Medical Center, Cleveland, OH, US; [2]Ohio State University School of Health and Rehabilitation Sciences, Columbus, OH, US; [3]Emory University, Atlanta, GA, US; [4]Lab of Molecular Microbiology, Bethesda, MD, US

Background: Life-saving, long-term anti-retroviral therapy (ART) is linked to increased risk of thromboembolism and cardiovascular co-morbidities. While immune activation, bacterial translocation, oxidative stress, and chronic vascular inflammation are the prime predicted triggering factors, a through mechanistic knowledge is still lacking. Here, we examined endothelium of SIV infected Rhesus macaque with the hypothesis that key markers of endothelial dysfunction and expression of Krüppel-like factor 2 (KLF2), a transcriptional master regulator of an anti-thrombotic endothelial environment, will be modulated.

Methods: Sections of paraffin-embedded thorasic aorta from SIV (SHIVSF162P3) infected and uninfected *Rhesus macaques* were used in this study. H&E staining to identify any morphological alteration or sub-endothelial infiltration of inflammatory cells and immunohistochemistry methods were applied to detect endothelial eNOS and KLF2 expression by epi-fluorescent microscopy (EVOS®FL). Public domain software ImageJ v1.38e was used for the digital image data analysis. We also investigated the *in vitro* effect of statin on KLF2 expression in human aortic endothelial cells.

Results: Focal endothelial proliferation, and sub-endothelial infiltrations at multiple sites were found in H&E stained sections of 3 out of 4 infected animals, compared to none in the 22 controls. This observation was further refined by immune-fluorescence detection of sub-endothelial monocytes (CD68+), T lymphocytes (CD8+), and platelets (CD41+) in the infected group. We observed significant reduction ($p < 0.001$) of eNOS expression in all 4 infected animals (Fig 1a). We also detected significantly lower ($p < 0.0001$) KLF2 expression in the endothelium of the infected animals (Fig 1b). Moreover, our results indicate that simvastatin protects human aortic endothelial cells from LPS and oxLDL induced down-regulation of KLF2.

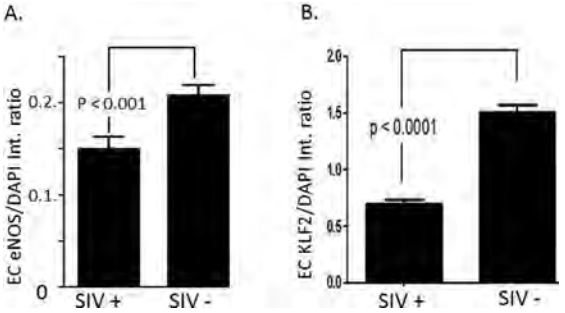


Figure1. *Endothelial Dysfunction and reduced Krüppel-like Factor expression in SIV infection:* A. Endothelial eNOS B. Endothelial KLF2 (cumulative data from 100 endothelial cells in each aortic section of 4 infected and 4 control animals).

Conclusions: Here we show for the first time direct evidence that SIV infected Rhesus macaques have dysfunctional vascular endothelium with sub-endothelial infiltration of inflammatory cells indicating early atherosclerotic changes. We also report for the first time a significant down-regulation of endothelial KLF2 in SIV infected animals. In addition, while lipid dysregulation and bacterial translocation may prime the initiation and maintenance of a pro-thrombotic endothelium in HIV infection, our *in vitro* data indicate that statin can protect endothelial cells from LPS and oxLDL induced KLF2 down-regulation.

299LB A Novel Method Using ^2H_2O to Measure Collagen Turnover in HIV-Infected Individuals

Leslie R. Cockerham[1]; Claire Emson[2]; Ma Somsouk[1]; Kara Harvill[1]; Kevin Li[2]; Scott M. Turner[2]; Martin L. Decaris[2]; Marc K. Hellerstein[3]; Steven G. Deeks[1]; Hiroyu Hatano[1]

[1]University of California San Francisco, San Francisco, CA, US; [2]KineMed, Inc, Emeryville, CA, US; [3]University of California Berkeley, Berkeley, CA, US

Background: Lymphoid tissue fibrosis occurs early in HIV infection and is thought to be a central factor in the pathogenesis of HIV by impairing T cell homeostasis. Collagen deposition is a dynamic process, and traditional histologic techniques cannot distinguish between new collagen deposition and any fibrosis that may have accumulated during the untreated phase of HIV infection. We investigated the use of a technique utilizing ^2H_2O (heavy water) intake to quantify new collagen deposition in gut-associated lymphoid tissue (GALT) in treated HIV-infected individuals.

Methods: Eighteen HIV-infected individuals on suppressive ART received outpatient oral doses of ^2H_2O for 4 weeks and underwent colorectal biopsies. ^2H_2O enrichment in total body water (TBW) in each patient was quantified from weekly salivary swabs during ^2H_2O administration. Single 3mm biopsy pieces were subjected to sequential physical and

chemical extraction methods to fractionate collagen molecules based on solubility in guanidine HCl. Guanidine-soluble collagen represents more recently synthesized, less cross-linked collagen. Incorporation of the ^2H_2O tracer into collagen in GALT was quantified by liquid-chromatography-mass spectrometry and fractional synthesis rate (FSR; per week) was calculated for guanidine-soluble and -insoluble GALT collagen.

Results: Outpatient administration of ^2H_2O was well tolerated. After 28 days of ^2H_2O intake, subjects reached the target goal of 1-2% ^2H_2O enrichment in TBW. The median FSR of guanidine-insoluble collagen in GALT was 3.2% per week (IQR 2.9%-3.9%). Guanidine-soluble collagen in GALT turned over much more quickly, with a median FSR of 12.8% per week (IQR 12.3%-16.1%). In comparison with other human studies where collagen FSR was measured by ^2H_2O labeling, the FSRs in GALT were 5-fold higher than the FSRs of skin collagen in healthy volunteers but similar to the FSR of liver collagen in patients with fibrotic liver disease.

Conclusions: The relatively high rates of collagen turnover observed in the GALT during treated HIV disease (guanidine soluble collagen half-life ~ 5 weeks) suggest that collagen deposition and turnover is ongoing and dynamic in this setting, and may therefore be amenable to interventions. The ^2H_2O labeling technique provides an assessment of collagen turnover rates, in contrast to static metrics from traditional histologic techniques, and may be useful for evaluating the effects of future anti-fibrotic therapies.

2:30 pm – 4:00 pm

HIV/CMV Interactions in Transmission and Pathogenesis

300 Effect of CMV and HIV Replication on T-Cell Exhaustion and Senescence During ART

Jennifer M. Dan[1]; Marta Massanella[1]; David M. Smith[1]; Eric S. Daar[2]; Michael P. Dube[3]; Richard Haubrich[1]; Sheldon Morris[1]; Sara Gianella Weibel[1]

[1]University of California San Diego, La Jolla, CA, US; [2]Harbor–University of California Los Angeles Medical Center, Torrance, CA, US; [3]University of Southern California Keck School of Medicine, Los Angeles, CA, US

Background: HIV-infected men who have sex with men (MSM) are nearly universally infected with CMV, and both viruses are associated with T-cell dysfunction and inflammation-related morbidities. The effect of asymptomatic CMV replication and persistent HIV transcription during suppressive ART on markers of T cell exhaustion and senescence is poorly defined.

Methods: Paired seminal and blood samples from 45 asymptomatic chronically HIV-infected CMV-seropositive MSM on long term ART and with HIV RNA levels in blood plasma <50 copies/ml were studied. Levels of CMV DNA in semen and blood were measured by RT-PCR, and cell-associated HIV DNA and RNA transcripts (unspliced) were measured in PBMC by droplet digital PCR. Markers of T cell exhaustion (PD-1) and senescence (CD57) were measured in PBMC by flow cytometry for CD4 and CD8 T cells and subsets (naïve [$CD45RA^+CD27^+CD28^+$], central memory [$CD45RA^-CD27^+CD28^+$], effectors [$CD4^+CD45RA^{-/+}CD27^-CD28^+$ or $CD8^+CD45RA^{-/+}CD27^+CD28^-$] and terminally differentiated [$CD45RA^{+/-}CD27^-CD28^-$]). Associations between immunological markers and asymptomatic CMV and HIV replication, HIV DNA, CMV IgG, age, current and nadir CD4 and time on ART were determined using univariate and multivariate analysis.

Results: CMV DNA was detected in 42% of seminal samples and 20% of PBMC. Detectable CMV DNA in semen but not blood was associated with increased PD-1 expression on circulating CD4 T cells compared to no CMV (P=0.01), particularly in the effector and terminally differentiated subsets (P<0.05). Similarly, higher levels of cellular HIV RNA (but not HIV DNA) were positively associated with greater PD-1 expression on total CD4 and central memory blood subset (P<0.01). There was no association between CMV DNA (blood and semen) or cellular HIV RNA with CD8 exhaustion or senescence or with markers of CD4 senescence. In multivariate analysis, detection of seminal CMV and higher cellular HIV RNA remained associated with increased PD-1 expression on total CD4 T cells (P<0.05). No other variable contributed significantly to the model.

Conclusions: Our data suggest that detection of CMV in the genital tract may contribute to the activation of the PD-1 axis on circulating T cells during suppressive ART. Because increased PD-1 on T cells has been implicated in the maintenance of the HIV reservoir, HIV disease progression and the inability of the immune system to adequately control HIV infection, future studies should examine whether CMV-dependent mechanisms play a role in T cell exhaustion.

301 HIV Myeloid Derived Suppressor Cells Control Cytomegalovirus Inflammation by IL-27

Ankita Garg; Stephen Spector

University of California San Diego, La Jolla, CA, US

Background: CMV is associated with persistent inflammation in HIV-infected persons. Here, we studied the effect of HIV expanded myeloid derived suppressor cells (MDSCs) in controlling CMV specific inflammation.

Methods: PBMCs from HIV–/CMV-seropositive (CMV+) donors were cultured in presence of heat inactivated HIV. After 5 days, $CD11b^+CD33^+CD14^+HLA\ DR^{hi}$ (DR^{hi} monocytes) and $CD11b^+CD33^+CD14^+HLA\ DR^{-/lo}$ (MDSCs) cell subsets were sorted by flow cytometry. B7H4 (a negative regulator of T cell function) was silenced using siRNA and cultured with/without autologous PBMCs in presence/absence of CMV pp65 peptides (pp65; 1μg/ml). In some experiments, PBMCs were cultured with HIV/pp65 in presence/absence of neutralizing anti-IL-27 antibody. Enumeration of B7H4 on MDSCs, regulatory T-cells, intracellular IFNγ, activated forms phospho(p)-Zap70 and p-Akt were determined by flow cytometry; IFNγ and IL-27 were quantified by ELISA. Data were analyzed using two-tailed, paired Student's *t* test.

Results: MDSCs cultured with autologous PBMCs exposed to pp65 caused a decrease in IFNγ production vs. controls or DR^{hi} monocytes (p=0.002). IFNγ release was restored when MDSCs were transfected with B7H4 siRNA and cultured with PBMCs in presence of pp65 (p=0.02). MDSCs cultured with PBMCs did not alter pp65 induced activation of proximal T-cell signaling molecule Zap70 but decreased activation of Akt; this was restored when B7H4 was knocked down in MDSCs cultured with PBMCs. Culture of MDSCs with pp65 produced more IL-27 vs. control MDSCs and DR^{hi} monocytes (p=0.05). Culture of CMV+ PBMCs with pp65 increased the frequency of $CD4^+IFN\gamma^+$ cells and release of IFNγ in supernatants vs. controls (p=0.04). IFNγ was further increased when PBMCs were cultured in presence of anti-IL-27 and stimulated with pp65; CMV– PBMCs did not produce IFNγ when treated with pp65. Furthermore, culture of CMV+ PBMCs with pp65 led to expansion of $FoxP3^+$ Tregs vs. controls (p=0.02) and CMV– (p=0.003); addition of anti-IL-27 had no effect on Treg expansion. Finally, HIV expanded MDSCs had increased expression of B7H4 when compared to DR^{hi} monocytes (p=0.03) which was inhibited in the presence of anti-IL-27 neutralizing antibody (p=0.05).

Conclusions: These findings suggest that IL-27 down regulates IFNγ during CMV infection. IL-27 induces B7H4 expression on HIV MDSCs which controls CMV induced T-cell IFNγ production by inhibiting p-Akt. IL-27 and B7H4 provide new therapeutic targets to control inflammation during HIV infection.

302 Persistent Elevation of Inflammation Markers in HIV+ Persons With CMV Disease

Melissa Schechter[1]; Bruno Andrade[2]; Eleanor M. Wilson[1]; Virginia Sheikh[2]; Sonya Krishnan[2]; Margaret Caplan[1]; Gregg Roby[2]; Adam Rupert[3]; Peter Burbelo[4]; Irini Sereti[2]

[1]NIAID, Leidos Biomedical Inc., Fredrick, MD, US; [2]National Institute of Allergy and Infectious Diseases, Bethesda, MD, US; [3]NIAID, Leidos Biomedical Inc., Fredrick, MD, US; [4]National Institute of Dental and Craniofacial Research, Bethesda, MD, US

Background: HIV+ individuals have a high prevalence of cytomegalovirus (CMV) co-infection and a minority of them develop CMV-associated end organ disease (EOD). CMV co-infection has also been associated with increased risk for cardiovascular events. The potential contribution of CMV infection or disease in chronic immune activation and non-infectious complications in HIV remains unclear.

Methods: In a case control study, HIV+ persons (CD4 <100 cells/μL pre-ART) with CMV EOD (N=25) or detectable CMV viremia (N=7) pre-ART were matched 1:1 by CD4 T-cell counts and age with HIV+ persons with undetectable CMV viremia by PCR. Participants were evaluated pre-ART (week 0) and at week (W) 12 and 48 after ART initiation. Cryopreserved plasma was used to measure markers of inflammation (CRP, IFN-γ, IL-12 p70, IL-10, IL-1β, IL-8, IL-6, TNF-α), monocyte activation and vascular injury (sICAM-3, E-Selectin, sCD14, sTF, MP-TF, CX3CL1, P-Selectin, Thrombomodulin, SAA, MCP-1, Eotaxin-3) and coagulation (D-dimer, Factor X Chromogenic, TF Chromogenic) by ELISA-based assays. Data were analyzed using Mann-Whitney and Spearman rank (correlation) tests.

Results: EOD cases were 66% male, with median age of 41 years, CD4 of 11 cells/μL, plasma HIV RNA of 5.12 $\log_{10}$ c/mL and CMV PCR 2.93 $\log_{10}$ c/mL units at W0. EOD cases had higher plasma levels of HIV RNA (p=0.01), CRP (p=0.03), IFN-γ (p=0.02), IL-10 (p=0.01), IL-8 (p=0.01), IL-6 (p=0.03), and SAA (p=0.001) compared to controls at W0. At W12, SAA (p=0.02), IFN-γ (p=0.0002), IL-10 (p=0.0003), IL-8 (p=0.01) and TNF-α (p=0.003) remained higher in EOD cases than in controls. At W48, IFN-γ (p=0.0.01), TNF-α (p=0.02) and IL-12 p70 (p=0.04) were persistently higher in EOD cases than in controls. Baseline, CMV IgG levels inversely correlated with sCD14 (r=-0.3, p=0.04), Fractalkine (r=-0.3, p=0.02) and HIV viral load (r=-0.33, p=0.01) but not with presence of EOD.

Conclusions: CMV end organ disease and viremia in HIV+ persons is associated with increased plasma levels of inflammatory and vascular injury biomarkers pre-ART with some persisting after ART. Our data suggest a protracted inflammatory response to CMV that may contribute to HIV pathogenesis and non-infectious complications.

Funded by NCI Contract No. HHSN261200800001E. This research was supported [in part] by the National Institute of Allergy and Infectious Diseases.

303 sCD163 Increase in HIV/CMV-Coinfected Subjects Included in ICONA Cohort

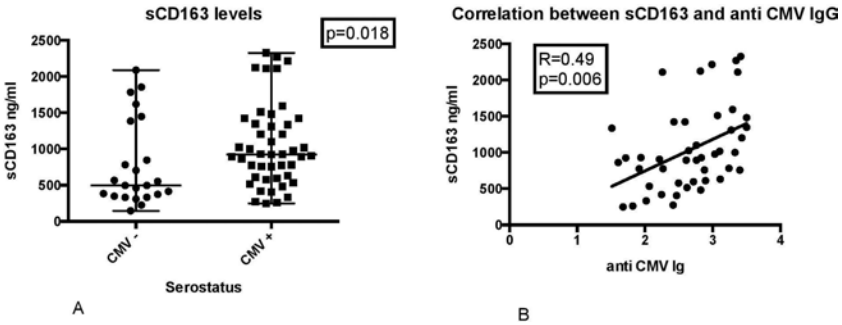
Serena Vita[3]; Miriam Lichtner[1]; Giulia Marchetti[2]; Claudia Mascia[3]; Esther Merlini[2]; Paola Cicconi[2]; Vincenzo Vullo[3]; Pier Luigi Viale[5]; Alberto Costantini[4]; Antonella d'Arminio Monforte[2]
For the Icona Foundation Study

[1]University of Rome La Sapienza, Polo Pontino, Latina, Italy; [2]San Paolo Hospital, Milano, Italy; [3]University of Rome La Sapienza, Rome, Italy; [4]University of Ancona, Ancona, Italy; [5]University of Bologna, Bologna, Italy

Background: Accumulating evidence suggest that inflammatory cytokines produced by monocytes/macrophages play a role in the vascular disease and cognitive decline**.** In HIV patients, herpes virus coinfection has been proposed as a key factor in sustaining immune activation, even in presence of HIV plasma viral control. In our previous study on the ICONA cohort we showed that in HIV patients (pts), CMV infection is an independent risk factor for non AIDS events/deaths.

Methods: We screened all the ICONA pts with an available CMV serology at enrolment (<= 6 months) and a plasma sample after ≥1 year of successful ART (defined as an undetectable HIV viral load and CD4+ count >200/mc). Pts were grouped according to CMV serostatus in CMV-infected (CMV+) (defined as CMV IgG positive) and CMV-uninfected (CMV-). Pts were also matched 2:1 for the following parameters: age, CD4 nadir, duration of HIV infection, HBV and HCV. We excluded pts with previous or current CMV organ diseases and other active organ disease in the previous 5 years. We detected sCD163, TNFα, sCD14, IL-6 using ELISA tests (R&D Systems) on plasma samples. All sample were retested for anti-CMV IgG (GenWay Biotech). Statistical analysis was performed using Mann-Withney Test and Spearman correlation analysis.

Results: A total of 69 subjects were recruited, 46 HIV monoinfected (CMV-) and 23 HIV/CMV (CMV+) coinfected. A higher median of sCD163 level (927.7 vs. 497.8 ng/ml, p=0.018) was found in CMV+ compared to CMV- group. TNFα, sCD14 were also elevated but didn't reach a significant difference in comparison to HIV/CMV- subjects. In HIV/CMV+ subjects a significant correlation was shown between anti-CMV IgG levels and sCD163 (r=0.49, p=0.006) (Fig.1). Moreover only in CMV+ subjects sCD163 levels were related to the duration of HIV infection (r=0.29, p=0.04). In the CMV positive group comparing CMV IgG levels with CD4 count, at the time of sampling, we found a significant negative correlation (r=0.39, p=0.0006).



Conclusions: CMV chronic infection appears to be linked to an increase in sCD163, a markers of myeloid activation, in HIV infected subjects under successful ART with controlled biological (age and sex) and HIV related (HIV suppression, CD4 nadir and CD4 recovery) factors. The persistent activation of monocytes and macrophages that has been implicated in the accelerated development of vascular and neurological disease in general population, may explain the increased risk of non AIDS events found in CMV/HIV coinfected subjects.

304 Genital CMV Shedding Predicts Syphilis Acquisition in HIV-Infected MSM on ART

Sara Gianella Weibel[1]; David M. Smith[1]; Eric Daar[2]; Michael Dube[3]; Andrea Lisco[4]; Christophe Vanpouille[5]; Richard Haubrich[1]; Sheldon Morris[1]

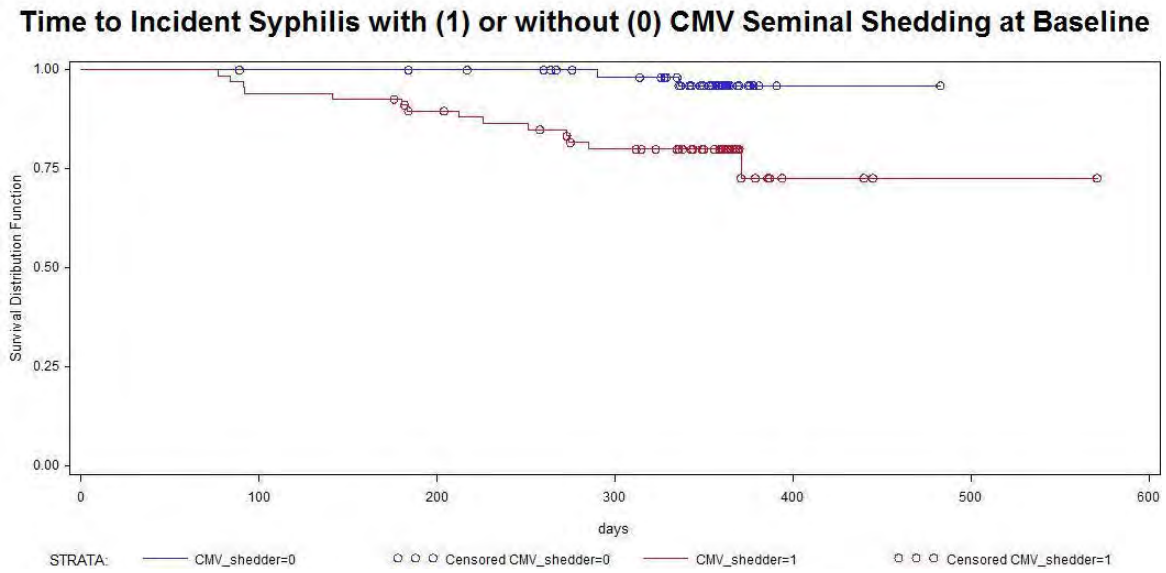
[1]University of California San Diego, La Jolla, CA, US; [2]Los Angeles Biomedical Research Institute at Harbor–UCLA Medical Center, Torrance, CA, US; [3]University of Southern California Keck School of Medicine, Los Angeles, CA, US; [4]National Institute of Allergy and Infectious Diseases, Bethesda, MD, US; [5]National Institute of Child Health and Human Development, Bethesda, MD, US

Background: Bacterial sexually transmitted infections (STI) are highly prevalent among HIV-infected men who have sex with men (MSM) and are co-factors in HIV transmission. While sexual behavior and networks are important in STI acquisition, other biological factors have not been emphasized as targets for intervention.

Methods: As part of a behavioral intervention, 136 HIV-infected MSM on suppressive (<500 copies/ml) ART were followed for 12 months and screened for incident bacterial STI (*Neisseria gonorrhoeae*, *Chlamydia trachomatis*, and syphilis*)* every three months. Baseline predictors of bacterial STI were determined using survival analysis of time to incident

STI. Tested variables at baseline included: behavioral factors (number of sex partners, number of anal sex acts, use of methamphetamine and other drugs), plasma HIV RNA levels, current and nadir CD4 T and CD8 T cell count, genital shedding of herpes viruses (CMV, EBV, HSV, HHV-6, -7, and -8), serum CMV IgG levels, and soluble markers of genital inflammation (MCP-1, IL-6, TNF-alfa, Interferon-gamma, RANTES and IP-10 in baseline seminal plasma).

Results: Thirty-four subjects (26.2%) acquired bacterial STIs during follow-up, sometimes with more than one pathogen (16 syphilis, 20 gonorrhea, 14 chlamydia). Acquisition of syphilis during follow-up was associated with genital CMV shedding at baseline (21% in CMV shedders versus 3% in non-shedders, P=0.003, see figure attached), younger age (P=0.005) and more sex partners (P=0.047). None of the tested variables except partner number was associated with acquisition of other STIs (chlamydia and gonorrhea at any site). For the acquisition of syphilis, in multivariable Cox-proportional hazard model adjusted hazard rates were as follows: baseline CMV shedding 4.87 (95% CI 1.06-22.47), age 0.96 (per year younger [95% 0.91-1.01]) and number of partners past month 1.06 (per partner per month [0.99-1.13]). Also, syphilis cases compared to non-cases had lower baseline levels of seminal MCP-1 (P=0.01), and lower seminal MCP-1 levels were associated with higher levels of seminal CMV DNA (P=0.005).



Kaplan-Meier Plot showing incidence of Syphilis acquisition in participant with (1) and without (0) CMV seminal shedding at baseline.

Conclusions: In this prospective study, presence of genital CMV shedding at baseline was strongly associated with acquisition of syphilis. Lower level of seminal MCP-1 was associated with both presence of genital CMV shedding and syphilis acquisition. Future studies with anti-CMV therapeutics could help determine underlying mechanisms and if causal associations exist.

2:30 pm – 4:00 pm

Aging and Immune Senescence

305 Early Start of ART Affects Late Markers of Immune Senescence

Sharon L. Karmon; Teresa H. Evering; Melissa La Mar; Martin Markowitz

Aaron Diamond AIDS Research Center, an Affiliate of the Rockefeller University, New York, NY, US

Background: Despite a dramatic increase in life expectancy, people with HIV on antiretroviral therapy (ART) continue to suffer from higher risks of morbidity and mortality, often due to non-AIDS related illnesses. It is hypothesized that this increased risk is in part due to ongoing immune activation and premature immune senescence. We studied whether initiation of ART during primary HIV infection (PHI) correlated with improved markers of inflammation and immune senescence.

Methods: We recruited 32 subjects: 12 HIV+ men who started ART during PHI (Group 1), 10 HIV+ men who deferred ART until chronic HIV infection (CHI, Group 2) and 10 HIV-negative controls (Group 3). All subjects were men who have sex with men (MSM) between 18 - 45 years old with no comorbid chronic infections, immune modulating conditions/treatments, or IV drug use, and matched for EBV, CMV and RPR status. HIV-positive subjects were stably virologically suppressed. We used subject serum and plasma samples to perform ELISA, ECL, and xMAP assays to measure levels of soluble factors. We cryopreserved peripheral blood mononuclear cells (PBMCs) for flow cytometric measurements.

Results: Group 1 subjects began ART 31 ± 9 days after their estimated date of infection (EDOI) with HIV-1 and had been treated for 8.1 years at the time of screening. Group 2 began ART 3.7 ± 1.6 years after their EDOI and had been treated for 5.3 years. Group 1 subjects had higher CD4 counts (901 versus 605 cells/mm^3 and CD4/CD8 T cell ratios (1.81 versus 0.89) compared to Group 2. The median plasma levels of inflammatory markers (CRP, fibrinogen, IL-1b, IL-6, TNF-a) were statistically the same between all groups (see table). Other markers of immune dysregulation (% monocytes, sCD14, CD8 T cell activation, Th17/Treg ratio) were equally abnormal in both HIV+ groups compared to the HIV-negative controls. However, Group 1 subjects did exhibit improved values in several markers of immune senescence (naïve/memory T cell ratio, % terminally differentiated CD8 T cells, % senescent CD4+ T cells, marker of vaccine response in CD4 T cells, CD8 T cell telomere lengths) compared to Group 2 subjects.

		Group 1 (HIV+, started ART during PHI)		Group 2 (HIV+, started ART during CHI)		Group 3 (HIV-negative)			
		Median	IQR	Median	IQR	Median	IQR	p-value	Results
Markers of immune senescence	Naïve/Memory T cell ratio	1.86	0.96 - 2.6	0.71	0.57 - 1.6	0.47	0.30 - 1.8	0.0360	G1 > G2/G3
	Terminally differentiated CD8+T cells (%CD27-CD28-)	19.1	15.2 - 32.0	39.1	30.0 - 44.8	22.7	9.4 - 34.1	0.0386	G2 > G1/G3
	Senescent CD4+ T cells (%CD28-CD57+)	1.54	1.2 - 1.9	3.29	1.7 - 5.6	1.12	0.89 - 2.6	0.0057	G2 > G1/G3
	Marker of vaccine response (%CD4+CD28+)	53.8	53.1 - 68.4	37.3	29.4 - 47.4	50.7	40.2 - 56.8	0.0006	G1 > G2
	Telomere lengths in CD8+ cells (relative to 1301 cells)	13.8	13.0 - 14.4	11.8	8.0 - 13.1	13.7	12.0 - 15.2	0.0116	G2 < G1/G3
Markers of immune activation / coagulation	Plasma CRP (mg/L)	0.36	0.19 - 0.95	0.24	0.13 - 0.32	0.22	0.13 - 0.60	0.2008	NS
	Plasma Fibrinogen (mg/dL)	207	165 - 444	196	180 - 325	175	147 - 247	0.3550	NS
	Plasma IL-1β (ng/mL)	0.26	0.18 - 0.32	0.23	0.08 - 0.34	0.23	0.15 - 0.38	0.5139	NS
	Plasma IL-6 (ng/mL)	0.93	0.54 - 1.2	1.02	0.76 - 1.6	0.90	0.62 - 1.0	0.2395	NS
	Plasma TNF-α (ng/mL)	6.18	5.0 - 8.2	6.38	5.7 - 8.8	5.00	4.2 - 5.4	0.9006	NS
	Monocytes (% of CD3- lymphocytes)	2.50	2.1 - 4.8	2.23	1.4 - 7.3	1.17	0.55 - 1.7	0.0300	G1/G2 > G3
	Serum sCD14 (ng/mL)	2035	1848 - 2280	1930	1805 - 2055	1510	1395 - 1605	0.0003	G1/G2 > G3
	Activated CD8+ T cells (% CD38+HLA-DR+)	1.45	1.2 - 2.5	1.80	1.2 - 2.6	1.11	0.60 - 1.4	0.0433	G1/G2 > G3
	Th17/Treg ratio	0.36	0.24 - 0.43	0.33	0.28 - 0.44	0.46	0.41 - 0.71	0.0145	G1/G2 < G3

Results of study assays. PHI = primary HIV infection; CHI = chronic HIV infection; ART = antiretroviral therapy; IQR = interquartile range; G1/G2/G3 = Groups 1/2/3; NS = non significant

Conclusions: Initiation of ART during primary HIV-1 infection correlated with normalization of markers of immune senescence. Timing of ART initiation did not appear to correlate with any difference in select markers of inflammation or immune activation. These improvements in senescence markers may further support early treatment in patients with HIV.

306 Chronic HIV Infection Exacerbates Cellular Aging Markers in Isolated T-Cell Subsets

Anthony Hsieh; Beheroze Sattha; Hélène Côté
CIHR Team in Cellular Aging and HIV Comorbidities in Women and Children (CARMA cohort)
University of British Columbia, Vancouver, Canada

Background: Shorter telomere in the expanded senescent $CD8^+$ T cell compartment is an age-related immunologic abnormality reported in a small cohort study of people living with HIV. This immune defect, along with imbalance in $CD4^+$ and $CD8^+$ T cell distributions may link chronic HIV infection with premature age-related comorbidities, even in people treated with combination ART (cART). Little is known about markers such as telomere length (TL) and mitochondrial DNA apparent oxidative damage (mtDNA AOD) in isolated immune compartments during HIV infection. Our objective was to characterize these aging markers in $CD4^+$ and $CD8^+$ T cell subsets, and explore the possible role of HIV/cART on modulating immune aging. We hypothesized that HIV infection and factors such as viral load or time since diagnosis would be associated with skewed immune aging markers.

Methods: In this pilot study, live PBMCs were obtained from 33 HIV^+ subjects and 10 HIV^- controls enrolled in the CARMA cohort study. FACS was used to isolate $CD4^+$, proliferative $CD8^+$ $CD28^+$, and senescent $CD8^+$ $CD28^-$ T cells, as well as $CD19^+$ B cells. Relative TL and mtDNA AOD were measured in all cell subsets with sufficient cell count using qPCR. Results were compared using Spearman's correlation, two-tailed Mann-Whitney tests, and ANCOVA.

Results: As expected, a decreased $CD4^+/CD8^+$ T cell ratio (n=43, median 0.24 vs. 1.75, $p<0.001$) and an expanded senescent $CD8^+CD28^-$ T cell subset (n=43, 39 vs 17% of total T cells, p=0.02) were observed in the HIV^+ group compared to the HIV^- group. HIV infection was associated with shorter TL in proliferative $CD8^+CD28^+$ T cells (n=27, 3.35 vs. 3.73, p=0.02), but not in $CD8^+CD28^-$ or $CD4^+$ T cells after adjusting for age. Within the entire cohort, older age was associated with shorter TL in $CD4^+$ (n=26, R=-0.45, p=0.02), and proliferative $CD8^+CD28^+$ (n=27, R=-0.47, p=0.01) but not senescent $CD8^+CD28^-$ cells (R=-0.06). MtDNA AOD correlated with lifetime cART duration in both $CD8^+CD28^-$ and $CD8^+CD28^+$ T cells (n=22, R=0.53, p=0.01, and n=22, R=0.45, p=0.04). No relationship was seen between current HIV viral load, CD4 current or nadir, or time since diagnosis, and the aging markers assayed here.

Conclusions: Taken together, these results suggest a potential relationship between HIV infection and shorter TL in proliferative $CD8^+$ T cells. In contrast, cART duration was related to mtDNA oxidative damage in $CD8^+$ T cells, suggesting that cumulative exposure may play a role in mitochondrial aging in this immune compartment.

307 Age Associated Increases in Markers of Microbial Translocation and Inflammation in HIV-1 Infection

Eileen Scully[1]; Ainsley Lockhart[1]; Lisa Huang[2]; Marisol Romero-Tejeda[1]; Mary Albrecht[4]; Chrstine D. Palmer[1]; Ronald Bosch[3]; Marcus Altfeld[1]; Daniel Kuritzkes[2]; Nina Lin[5]
[1]Ragon Institute of MGH, MIT and Harvard, Jamaica Plain, MA, US; [2]Brigham and Women's Hospital, Boston, MA, Boston, MA, US; [3]Harvard School of Public Health, Center for Biostatistics in AIDS Research, Boston, MA, US; [4]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, US; [5]Boston University School of Medicine, Boston, MA, US

Background: The aging of the HIV-1 infected population obligates a focus on the interaction of the virus with aging and comorbid conditions. Enhancing the survival and quality of life of infected individuals requires identification of the etiologic drivers of these pathologies in order to disrupt pathways leading to non-AIDS morbidity and mortality.

Methods: We recruited a cohort of HIV-1 infected men aged ≤35 years (n=22) or ≥50 years (n=23) on fully suppressive antiretroviral therapy (ART). Cryopreserved PBMCs were analyzed for T cell activation, exhaustion, proliferation, and innate cellular subsets. Functional capacity of the innate compartment was assessed by intracellular cytokine staining after stimulation with a panel of Toll-like receptor (TLR) agonists. Plasma markers of inflammation were measured, and selected analytes compared to an age-matched cohort of 46 uninfected men.

Results: No differences in T cell activation, exhaustion, proliferation or CD4/CD8 ratio were observed between age groups. Distributions of monocyte subsets (classical, nonclassical and intermediate), and myeloid and plasmacytoid dendritic cells were comparable. Innate functional capacity as measured by TNFa, IL-1b and IP-10 production by the relevant cell populations was not significantly different in response to TLR2, TLR3, TLR4, and TLR7/8 agonists. Analysis of plasma levels of cytokines identified elevated expression of the chemokine MCP-1 in the older age stratum ($p<0.05$, Mann-Whitney), which was confirmed by increased levels of mRNA expression ($p<0.05$). The ≥50 age group also showed higher levels of LPS as measured by the LAL assay ($p<0.05$). When compared to a group of uninfected control subjects, older HIV-1 infected adults were more frequently in the upper quartile of sCD14 expression (OR 4.12, 95% CI 1.06-16.0, $p<0.05$, chi square) compared to the age ≤35 HIV-infected and uninfected groups.

Conclusions: In a cohort of HIV-infected individuals well-matched on virologic parameters and separated into age strata, there was a significant difference in levels of plasma MCP-1 and markers of microbial translocation in the absence of significant differences in adaptive or innate cellular markers of immunosenescence, or in the functional assessment of innate immune capacity. Together, the data suggest that exploration of MCP-1 and LPS as a potential early signature of risk for age-related comorbidities is warranted.

Immune Pathogenesis of IRIS

308 Vitamin D, D-Dimer, IFNγ and sCD14 Predict IRIS in a Prospective Multicenter Study

Laura W. Musselwhite[1]; Ann Tierney[2]; Susan Ellenberg[2]; Pablo F. Belaunzarán-Zamudio[5]; Adam Rupert[3]; Ian Sanne[4]; Michael M Lederman[6]; Juan Sierra-Madero[5]; Irini Sereti[7]

[1]Duke University, Durham, NC, US; [2]University of Pennsylvania, Philadelphia, PA, US; [3]Leidos Biomedical Inc., Reston, VA, US; [4]University of the Witwatersrand, Johannesburg, South Africa; [5]Instituto Nacional de Ciencias Medicas y Nutricion, Mexico City, Mexico; [6]Case Western Reserve University, Cleveland, OH, US; [7]National Institutes of Health (NIH), Bethesda, MD, US

Background: Immune reconstitution inflammatory syndrome (IRIS) in AIDS patients initiating anti-retroviral therapy (ART) is driven by immune dysregulation mechanisms. Biomarkers are needed to identify patients at risk.

Methods: Two hundred sixty-seven ART naïve patients with CD4 <100 cells/uL were enrolled in a multicenter, randomized placebo controlled ART initiation trial in South Africa and Mexico to test whether maraviroc added to an ART regimen could prevent IRIS. Participants were followed longitudinally for 6 months and IRIS events were reviewed prospectively based on the ACTG criteria. Pre-ART cryo-preserved plasma was used to measure cytokines (IFNγ, TNFα, IL-1β, IL-6, IL-10, IL-17), markers of myeloid cell activation (sCD14, sCD163), coagulation (D-dimer), CRP and vitamin D. Biomarkers with skewed distributions were log transformed prior to comparisons. Biomarkers in patients who developed IRIS were compared to the remaining cohort that did not develop IRIS after 6 months of follow-up. Biomarkers were then individually tested while adjusting for significant covariates selected through forward stepwise selection.

Results: Participants had a median age of 36, median CD4 count of 43 cells/μL, and median HIV-RNA 5.4 log10 copies/mL. Sixty-two participants developed IRIS and of these 21% were TB-IRIS. Patients who developed IRIS were more likely to be male (79% vs. 62%), with a prior AIDS–defining illnesses (79% vs. 54%), and a lower median hemoglobin (11.9 vs. 12.3 g/dL). Prior to ART, lower vitamin D, higher D-dimer, IFNγ, and sCD14 were independently associated with risk for IRIS in a multivariate analysis. A subgroup analysis of TB-IRIS cases (N=21) vs. patients without TB-IRIS was performed and revealed baseline levels of IFNγ, CRP, and sCD14 were independent predictors of TB-IRIS risk, while vitamin D levels were not associated with TB-IRIS in univariate or multivariate analyses.

Table 1. Biomarker levels in AIDS patients

Biomarker	IRIS	No IRIS	Unadjusted p-value	Adjusted p-value
IFNγ (pg/mL)	5.65 (2.25, 10.6)	2.72 (1.44, 5.17)	<0.001	0.01*
CRP (mg/L)	4.54 (1.84, 13.7)	2.47 (1.27, 8.99)	0.03	0.28
IP-10 (pg/mL)	3.43 (3.19, 3.59)	3.31 (3.10, 3.49)	0.005	0.16
TNFa (pg/mL)	19.9 (15.4, 28.1)	15.5 (12.1, 21.9)	0.042	0.23
sCD14 (μg/mL)	2400 (1988, 3235)	2014 (1645, 2471)	<0.001	0.01*
IL-6 (pg/mL)	2.48 (1.49, 4.02)	1.71 (1.23, 3.08)	0.048	0.48
IL-8 (pg/mL)	10.5 (6.61, 15.4)	7.62 (4.84, 13.8)	0.04	0.79
IL-10 (pg/mL)	14.0 (9.38, 20.3)	7.60, 15.7)	0.04	0.19
Vitamin D (ng/mL)	8.22 (4.99, 13.8)	9.65 (5.83, 17.9)	0.038	0.04*
D-Dimer (mg/L)	1.32 (0.84, 2.34)	0.85 (0.52, 1.52)	<0.001	0.008*

Data represent medians with interquartile ranges. * Denotes significance after multivariate adjustment for gender, hemoglobin, and prior AIDS-defining illness.

Conclusions: Biomarkers of T cell and monocyte activation (IFNγ, sCD14), coagulation (D-dimer) and low vitamin D prior to ART initiation are independently associated with IRIS. Further evaluation of these biomarkers as possible clinical prediction tools or targets of intervention for IRIS prevention is warranted.

309 LC-MS Analysis of Metabolites Differentiating IRIS From Non-IRIS in ACTG Study A5221

Mary A. De Groote[1]; Laura Ashton[1]; Marisa Harton[1]; Sam Bokatzien[2]; Kristofor Webb[1]; Carlos Adriano Matos de Silva[1]; Reem Al-Mubarak[1]; Sebabratra Mahapatra[1]; Diane Havlir[3]; John Belisle[1]

[1]Colorado State University, Fort Collins, CO, US; [2]National Jewish Health, Denver, CO, US; [3]University of California San Francisco, San Francisco, CA, US

Background: Immune reconstitution inflammatory syndrome (IRIS) occurs with potent treatment of HIV in the setting of co-infections such as *M. tuberculosis* (Mtb). IRIS is associated with substantial morbidity and mortality. We sought to better understand this syndrome and to develop a metabolic biosignature in plasma from subjects that developed IRIS. Samples were obtained from subjects enrolled in the immediate treatment arm of ACTG study A5221.

Methods: Subjects from the IRIS and Non-IRIS were matched for age, gender, and CD4 cells by the ACTG Data Center. Plasma samples from as many as 3 time points per subject (entry, IRIS window and follow-up) were analyzed. Plasma was extracted in triplicate with methanol and analyzed by liquid chromatography-mass spectrometry (LC-MS). LC-MS data were analyzed with Mass Profiler Professional (MPP) software (Agilent, Inc.) and XCMS online (Scripps Institute) to select molecular features (MFs) that distinguished IRIS and non-IRIS samples based on statistical significance.

Results: Each triplicate revealed 2,000-5,000 MFs and these were down selected based on a FC of 1.5 between IRIS and non-IRIS at each time point with a significance of $p<0.05$. The greatest difference between the IRIS and non-IRIS samples was observed with the IRIS window time point and included 59 MFs for all replicates analyzed. Four metabolomics databases (METLIN, HMDB, MTB LIPID MAPS and LIPID MAPS) were searched to provide a putative identification of the MFs. MF presumed to be small peptides and lipids (triglycerides, glycosphingolipids, vitamin D metabolites) dominated the signature. Some of the putative lipids are in well-known inflammatory pathways. Each significant MF was manually crossed checked against our in-laboratory Mtb lipid database and no matches were found, leading us to believe that the lipid molecules identified are of host origin. Targeted LC-MS analyses are currently underway to confirm identities and further assess changes in lipid metabolism of IRIS subjects.

Conclusions: These studies provide evidence that a biosignature based on metabolites can separate IRIS from non-IRIS early in the course of disease and may be able to predict those at risk for IRIS. Lipid species appear in our discriminatory signature. Efforts are ongoing to formally identify each of the significant MF we discovered. Ultimately we aim to confirm and validate our findings using samples collected in prospective trials or sites studying HIV/Mtb co-infected individuals who develop IRIS.

310 Associations Between Plasma Cytokine and Microbial Translocation Biomarkers and IRIS

Margaret A. Fischl[2]; Linda J. Harrison[1]; Varghese George[2]; Margaret Roach[2]; Xiao-Dong Li[3]; David Asmuth[3]; Pablo Tebas[4]; Camlin Tierney[1]; Catherine Godfrey[5]; Savita Pahwa[2]

[1]Center for Biostatistics in AIDS Research, Harvard School of Public Health, Boston, MA, US; [2]University of Miami Miller School of Medicine, Miami, FL, US; [3]University of California Davis, Sacramento, CA, US; [4]University of Pennsylvania, Philadelphia, PA, US; [5]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD, US

Background: IRIS is a pathogen-specific inflammatory response associated with ART initiation. We conducted a nested case-cohort study among subjects in a large prospective randomized longitudinal clinical trial (A5202) in the USA and investigated 18 plasma biomarkers of inflammation and microbial translocation for their association with risk of IRIS.

Methods: ACTG A5202 compared ABC/3TC or TDF/FTC combined with ATV/r or EFV for first-line HIV treatment. IRIS events were defined using ACTG criteria; unmasking and paradoxical events were included. 51 of 1452 subjects with baseline CD4<350 cells/mm^3 developed IRIS (3.9 cases/100 person years). We analyzed 100 randomly selected subjects (94 non-IRIS, 6 IRIS, stratified by pre-enrollment CD4≤200 cells/mm^3) and 45 additional IRIS cases. Plasma samples at baseline (n=141), an early time-point (~week 4, n=138) and week 48 (n=136) were tested for tumor necrosis factor (TNF), sTNF receptor I, sTNF receptor II, granulocyte colony stimulating factor (G-CSF), monocyte chemoattractant protein 1 (MCP-1), interferon (IFN) gamma, IFN alpha 2, IFN gamma inducible protein 10 (IP-10), IL-1 beta, IL-2, IL-6, IL-8, IL-10, IL-12, IL-17, sCD14 (ELISA, Luminex or electrochemiluminescence), lipopolysaccharide (LPS, Limulus amebocyte lysate assay) and 16s ribosomal (r) DNA(PCR).

Cox models, stratified by pre-enrollment CD4 and weighted for the case-cohort design, evaluated associations between baseline biomarkers and time to first IRIS event. Logistic models evaluated associations between biomarker levels at week 4 and 48 and IRIS.

Results: The 145 subjects included 79% male (34% with AIDS history), median age 39 years, baseline HIV-1 RNA 4.8 (IQR 4.6-5.4) $\log_{10}$c/ml, CD4 84 (30-184) cells/mm^3.

At baseline, higher IP-10, LPS, sCD14, 16s rDNA and IFN alpha 2 were associated with greater risk of IRIS (Table). There was a significant (p=0.012) non-linear relationship between MCP-1 and IRIS. These results were supported by adjusted models; other biomarkers had p≥0.15.

Most biomarkers (TNF, sTNFRII, G-CSF, MCP-1, IP-10, IL-8, IL-10, IFN alpha 2, LPS, sCD14) decreased after ART initiation. IP-10 and LPS at week 4 were still associated with IRIS. At week 48, this association only remained for IP-10.

Table Title: Biomarkers with Significant (p-value <0.05) Associations with IRIS

Time-point	Biomarker	Inter-Tertile Range (33rd-67thcentile) or %>detection limit	Effect Type	Unadjusted RR, 95% CI	Unadjusted P-value	Adjusted RR, 95% CI	Adjusted P-value
Baseline	IP-10 (pg/ml) (n=137)	1370-3795	per inter-tertile range	1.6 (1.2, 2.2)	0.005	1.7 (1.1,2.5)	0.014
	LPS (pg/ml) (n=141)	162-228	per inter-tertile range	1.7 (1.3, 2.3)	<0.001	1.8 (1.2,2.6)	0.006
	sCD14 (ng/ml) (n=141)	1580-2082	per inter-tertile range	2.1 (1.5, 3.0)	<0.001	2.1 (1.2,3.7)	0.008
	16s rDNA (copies/ul) (n=141)	32-58	per inter-tertile range	1.4 (1.1, 1.9)	0.017	1.4 (1.1,2.0)	0.018
	IFN alpha 2 (pg/ml) (n=141)	46%	≤10.9 (detection limit) >10.9	1.0 (ref) 2.8 (1.4, 5.6)	0.003	1.0 (ref) 3.4 (1.3, 9.0)	0.011
	MCP-1 (pg/ml) (n=141)	218-342	lower tertile middle tertile upper tertile	1.0 (ref) 0.5 (0.2, 1.3) 2.1 (1.0, 4.5)	0.005	1.0 (ref) 0.4 (0.1, 1.1) 1.4 (0.5, 3.8)	0.042
Early (~Week 4)	IP-10 (pg/ml) (n=123)	699-1745	per inter-tertile range	1.6 (1.2, 2.2)	0.004	1.6 (1.1,2.2)	0.008
	LPS (pg/ml) (n=138)	174-244	per inter-tertile range	2.2 (1.5, 3.3)	<0.001	2.3 (1.5,3.6)	<0.001
Week 48	IP-10 (pg/ml) (n=131)	402-849	per inter-tertile range	1.4 (1.1, 1.8)	0.004	1.4 (1.1,1.9)	0.010
	LPS (pg/ml) (n=136)	148-204	per inter-tertile range	1.4 (1.0, 1.9)	0.095	1.2 (0.8,1.8)	0.34

Table Footer: IP-10, LPS and soluble CD14 were modeled on the $\log_{10}$ scale, RR = risk ratio (hazard ratio at baseline and risk ratio at early and week 48 time-points), CI = confidence interval, Unadjusted = adjusted for pre-enrollment CD4 ≤200 cells/mm^3 by design, Adjusted = additionally adjusted for baseline HIV-1 RNA, CD8 percent, history of AIDS, and randomized ACTG A5202 treatment

Conclusions: Enhanced systemic inflammatory response presumably through persistent monocyte activation and bacterial translocation in immunosuppressed patients appear important in the pathogenesis of IRIS and may be useful to predict risk for IRIS

311 Potential Role of IL-1 and IL-10 Pathways in IRIS Pathogenesis

Ainhoa Perez-Diez; **Elizabeth Richards**; Stig Jensen; Eleanor M. Wilson; Virginia Sheikh; Maura M. Manion; Bruno Andrade; Timothy Myers; Irini Sereti

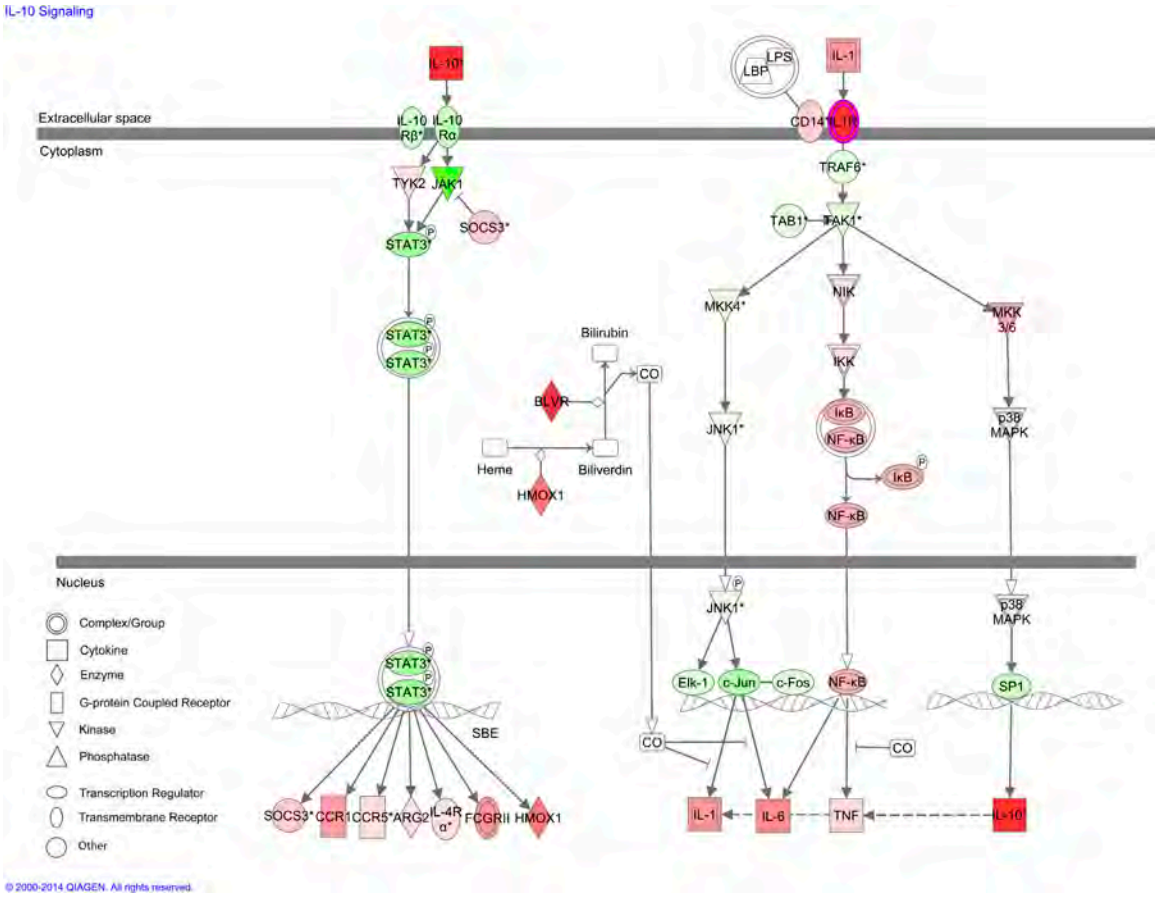
National Institute of Allergy and Infectious Diseases (NIAID), Rockville, MD, US

Background: Inflammation and immune activation play a central role in HIV pathogenesis. An exuberant inflammatory response, termed Immune Reconstitution Inflammatory Syndrome (IRIS), occurs in a subset of patients shortly after starting antiretroviral therapy (ART), and is more common in those with severe lymphopenia and underlying opportunistic infections. The pathogenesis and etiology of IRIS remain unclear. Microarray analysis of patient samples prior to ART initiation could allow the unbiased study of genes and molecular signatures in patients before they develop clinical manifestations of IRIS and help us understand the molecular pathways triggering the syndrome.

Methods: Gene expression profiles were measured by microarray analysis of peripheral mononuclear cells (PMC) obtained before ART from 143 HIV+ patients. Data were initially analyzed by the non-supervised method Principal Component Analysis (PCA), followed by supervised methods using Ingenuity Pathway Analysis (IPA). To detect which molecular

pathways (if any) might be over-represented in patients that would later develop IRIS we focused on biological function terms as well as upstream regulators that showed statistical significance of 10^{-7} in IPA.

Results: From a completed longitudinal cohort of ART-naive patients with CD4 <100 cells/μL starting ART, PMC were available from 143 patients pre-ART. Patients had a median age of 38 (IQR 30-45) years, CD4 22 (IQR 9-48) cells/μL and plasma HIV VL 4.99 (IQR 4.45-5.36)$\log_{10}$ copies/mL. Thirty six of them (25%) developed IRIS, based on ACTG criteria, at a median of 29 (IQR 7-56) days after ART initiation. PCA did not result in clear discrimination of PMC from IRIS versus non-IRIS patients, suggesting that at the time of analysis, before ART initiation, both groups looked similar at the molecular level. The most striking biological theme suggested by IPA analysis was expression of specific gene subsets associated with inflammatory responses and apoptosis/necrosis. Specifically, the IL-10 and IL-1 molecular pathways were highlighted in IRIS samples (Figure).



Differential gene expression for transcripts canonical pathway "IL-10 Signaling". Literature curated interactions between gene products are portrayed by shapes indicating type of gene product, while colors indicate the magnitude of difference in mRNA expression observed in this study. Transcripts in red were more abundant in IRIS patients, in green were more abundant in non-IRIS.

Conclusions: This study highlights possible molecular pathways, such as IL-1 and IL-10, involved in IRIS etiology that might have important implications for IRIS prevention and treatment. In addition, these findings may have implications for the diagnosis and treatment of complications in patients recovering from lymphopenia caused by etiologies besides HIV.

Immune Activation and HIV Pathogenesis

312 Inflammatory Biomarkers Decline but Do Not Normalize After 10 Years of cART

Kenneth A. Lichtenstein[1]; Carl Armon[2]; Vijaya Knight[1]; Rafeul Alam[1]

[1]National Jewish Health, Denver, CO, US; [2]Children's Hospital Colorado, Aurora, CO, US

Background: HIV infection is characterized by a state of chronic inflammation (CI). The degree to which combination antiretroviral therapy (cART) contributes to or ameliorates CI over time is unclear.

Methods: We measured levels of several inflammatory biomarkers (IB) in the 10 year period following initiation of cART in 327 patients participating in the Study to Understand the Natural History of HIV Infection in the Era of HAART (SUN Study) who had HIV-RNA levels < 200 copies/ml at each measurement. IB levels were measured in the specimen proximal to initiation of cART in 40 cART-naïve (cART-N) SUN Study patients and in a single specimen obtained from each of 30 case-matched HIV-negative controls (HNC). Baseline characteristics were similar between cART-experienced (cART-E) and cART-N groups. Frozen serum specimens were analyzed for RANTES, TNF-alpha, MIP-1 alpha and beta, MCP-1,

and Interleukin (IL)-6, IL-7, and IL-15. In the cART-E group, IBs were measured at study entry, 2 years and 6 years. We stratified the 3 IB samples by number of years receiving continuous cART. We used the Kruskal-Wallis test of medians to compare IB levels from the cART-E vs. the cART-N and HNC groups.

Results: Over the 10 years following initiation of ART, IB levels in the cART-E group were significantly higher vs. those of HNCs ($p < 0.05$) excepting IL-7 which was not significantly different (NS) vs. HNCs. In the first 4-5 years IB levels in the cART-E groups initially rose and then declined to levels below those of the cART-N group but the differences were NS with the exception of MIP-1 alpha that was lower for the last 3 years and IL-6, IL-15, and MCP-1 that were lower in year 10 ($p < 0.05$, for all). For each year, there were no significant differences in IBs in the PI vs. NNRTI groups.

Median biomarker values among 327 SUN Study patients who had viral loads < 200 copies/mL when biomarker levels were done by years of ARV experience compared to median values among 40 ARV naives and 30 HIV-negative matched controls

Year	N	RANTES	p. naives	p. controls	TNF-α	p. naives	p. controls	MIP-1α	p. naives	p. controls	MIP-1β	p. naives	p. controls	IL-6	p. naives	p. controls	IL-7	p. naives	p. controls	IL-15	p. naives	p. controls	MCP-1	p. naives	p. controls

Naives	N=40	10087			11.43			795			198			5.49			14.99			4.31			370		
Controls	N=30	9868			0.00			256			147			0.00			1.45			0.00			146		

Legend: ↑=p-value indicates significantly higher (p<0.05) median value compared to naives or controls; ↓=p-value indicates significantly lower (p<0.05) median value compared to naives or controls; · = non-significant difference compared to naives or controls. Statistical test used: Kruskal-Wallis test of medians.

Conclusions: After 10 years of cART, levels of IBs decline but remain elevated vs. HNCs. There were no significant differences in levels seen with PI vs. NNRTI based cART.

313 Persistently High IL-18 and sCD14 Are Independently Associated With Clinical Failure

Ashwin Balagopal[1]; Nikhil Gupte[1]; James Hakim[2]; Mina C. Hosseinipour[3]; Nagalingeswaran Kumarasamy[4]; Andrea Cox[1]; Ian Sanne[7]; David Asmuth[5]; Thomas Campbell[6]; Amita Gupta[1]
On behalf of the ACTG

[1]Johns Hopkins University School of Medicine, Baltimore, MD, US; [2]University of Zimbabwe, College of Health Sciences, Harare, Zimbabwe; [3]University of North Carolina, Chapel Hill, NC, US; [4]Y.R.G. Care, Chennai, India; [5]University of California San Diego, San Diego, CA, US; [6]University of Colorado, Denver, CO, US; [7]ACTG, Washington, DC, US

Background: Inflammation drives clinical progression in HIV-infected persons. Antiretrovirals (ARV) partially reduce inflammation. We studied the effect of persistent inflammation on clinical failure during ARV among multi-country ACTG 5175 trial participants.

Methods: In a nested case-control study, cases were clinical failure, defined as incident WHO stage 3/4 HIV disease or death from weeks 24 to 96 weeks; controls were without clinical failure and randomly selected. IL-6, IP-10, IL-18, TNFα, IFNγ and sCD14 levels were measured pre-ARV and at week 24 of ARV (ARV24). Persistent inflammation was defined as highest quartile levels (>Q3) pre-ARV and at ARV24 for IL-6(>48.3pg/mL),IP-10(>2856pg/mL),IL-18 (>774pg/mL), sCD14 (>6.4$\log_{10}$pg/mL), TNFα(>28.4pg/mL), and IFNγ(>48pg/mL), compared to lower quartiles(≤Q3). Poisson regression analysis was used to estimate RRs, adjusting for baseline age, sex, treatment, country, CD4, $\log_{10}$HIV RNA, prevalent TB, and viral suppression at ARV24 (HIV RNA<400 cp/ml).

Results: Of 99 cases and 233 controls, available samples were tested (**Figure**). Median age was 34 years; 160 (48%) were females. Median (IQR) CD4 was 181 (96-229) cells/μL and median (IQR) HIV RNA level was 5 (4.5-5.5) $\log_{10}$ cp/mL. At ARV24, 276 (87%) persons were virologically suppressed; median (IQR) CD4+ T cell count was 290 (197-388) cells/μL. Persistently high levels of IL-18 and sCD14 at ARV24 were independently associated with clinical failure [IL-18 RR (95%CI) 3.59 (1.48–8.74), p<0.05; sCD14 RR (95%CI) 2.21 (1.01–4.80), p<0.05]. High levels of IFNγ were independently associated with decreased risk of clinical failure [RR (95%CI) 0.08 (0.01–0.66), p<0.05]. Other markers at ARV24 were not associated with clinical failure. Restricting the analysis to subjects who were virologically suppressed at ARV24 maintained associations with IL-18 and IFNγ [IL-18 RR (95%CI) 3.10 (1.08–9.02), p<0.05; IFNγ RR (95%CI) 0.07 (0.01 – 0.64), p<0.05]; the association with sCD14 diminished in significance [RR (95%CI) 2.0 (0.77 – 5.25), p=0.16].

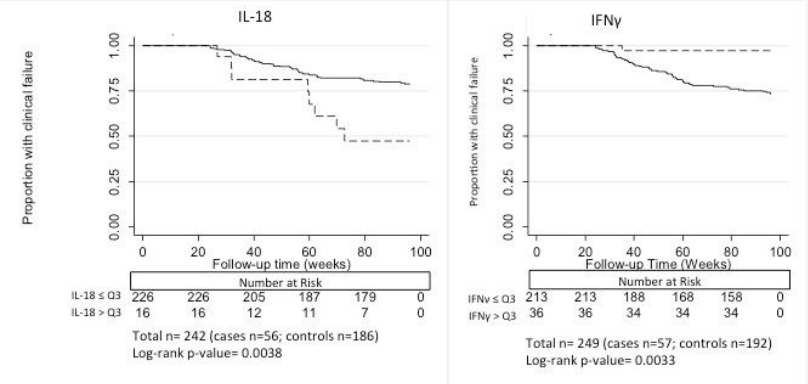

Figure. Kaplan-Meier survival estimates of HIV-infected persons initiating ARV in multi-national settings and their rate of developing clinical failures in persons with high (>Q3) compared to low (≤Q3) inflammatory marker levels.

Conclusions: IL-18, a highly pro-inflammatory cytokine linked to organ damage, was associated with clinical failure in persons who were virologically suppressed in diverse settings, suggesting that persistent inflammation in HIV-infected persons on ARV may contribute to further disease progression. Unexpectedly, IFNγ levels were inversely related to the risk of clinical failure, suggesting a link with immune restoration.

314 Impact of Partner HIV Status on Immune Activation and Inflammation During Chronic HIV

Shameem Z. Jaumdally[1]; Pamela Gumbi[1]; Hoyam Gamieldien[1]; Anabela Picton[2]; Caroline Tiemessen[2]; Lindi Masson[1]; Lenine Liebenberg[3]; David Coetzee[1]; Anna-Lise Williamson[1]; Jo-Ann Passmore[1]

[1]University of Cape Town, Cape Town, South Africa; [2]National Institute for Communicable Diseases, National Health Laboratory Service, Johannesburg, South Africa; [3]Centre for AIDS Programme Research in South Africa, Durban, South Africa; [4]University of Cape Town, Cape Town, South Africa

Background: The role of immune activation and inflammation on the rate of HIV disease progression has been proposed as a critical determinant of pathogenesis, but the mechanism is not fully understood. HIV+ individuals with HIV- partners (discordant relationship) versus HIV+ partners (concordant relationship) provide valuable insight to the role of continued HIV exposure on the clinical course of HIV infection. This study compared the impact of systemic viral load, T cell activation and inflammatory cytokine profiles on rate of disease progression in HIV+ concordant and discordant couples.

Methods: The impact of sexual partner status on systemic immune activation and inflammatory cytokine production in HIV+ individuals in HIV concordant (n=195) or discordant (n=142) long-term relationships was determined by flow cytometric analysis and luminex assays. Sequencing and qPCR were performed to determine CCR5 haplotypes.

Results: HIV+ concordant individuals had 0.5 Log_{10} higher plasma viral loads than HIV+ discordant ones ($p<0.0001$), and this was maintained over 24 months. However, this did not predict worse disease outcome (measured by absolute blood CD4 counts at later time points). HIV+ concordant individuals had higher frequencies of activated T-cells (CD3+CD38+CCR5+) in blood than HIV+ discordant counterparts. Individuals with plasma HIV loads >1500 copies/ml had higher frequencies of CD4+CCR5+ ($p=0.007$), CD8+CD38+ ($p=0.01$) and CD8+HLA-DR+CD38+ ($p=0.01$) T-cells compared to individuals with plasma viral loads <1500 cps/ml. CCR5 promoter haplotypes were not found to be a determinant in the CCR5 expression levels by T-cells. HIV+ concordant individuals had significantly higher concentrations of IL-1β ($p=0.04$) and TNF-α ($p=0.03$) in plasma than HIV+ discordant individuals. In women, plasma viral loads predicted genital tract viral loads ($Rho=0.65$; $p<0.0001$), with HIV+ concordant women having higher genital viral loads than HIV+ discordant women ($p=0.001$). HIV+ women with detectable HIV in genital secretions had higher genital concentrations of IP-10 ($p=0.002$), IL-1α ($p=0.007$), IL-1β ($p=0.004$), IL-6 ($p=0.005$), IL-8 ($p=0.008$), MCP-1 ($p=0.03$), MIP-1β ($p=0.01$), IL-10 ($p=0.01$), and G-CSF ($p=0.002$) than those with no detectable genital HIV.

Conclusions: This study suggests that partner's HIV status influences systemic viral loads, immune activation and inflammation, and is potentially a key factor ensuring continued HIV replication, but did not influence disease outcome.

315 Pretherapy Inflammation and Long-Term CD4 Response to Antiretroviral Therapy

Amit C. Achhra[1]; Andrew N. Phillips[2]; Sean Emery[1]; Rodger D. MacArthur[3]; Hansjakob Furrer[4]; Stéphane De Wit[5]; Marcelo H. Losso[6]; Matthew G. Law[1]
On behalf of the INSIGHT SMART and FIRST Study groups

[1]Kirby Institute, University of New South Wales, Sydney, Australia; [2]University College London, London, United Kingdom; [3]Wayne State University, Detroit, MI, US; [4]University Hospital Bern, Bern, Switzerland; [5]Saint-Pierre University Hospital, Brussels, Belgium; [6]Hospital J.M. Ramos Mejía, Buenos Aires, Argentina

Background: Pre-antiretroviral therapy (ART) inflammation/ coagulation activation predict clinical outcomes. However, it is unknown whether these processes result in blunted CD4+ count (CD4) responses to ART, thereby resulting in clinical outcomes. The objective of this analysis was to perform exploratory analyses assessing whether pre-ART inflammatory marker levels predicted the CD4 response to ART.

Methods: Analyses were based on data from the SMART and FIRST trials. The SMART study was an international trial evaluating continuous (viral suppression (VS) versus interrupted (drug conversation (DC)) ART and the FIRST trial evaluated 3 first-line ART regimens with ≥2 classes. For this analysis, participants had to be ART-naïve or off ART at randomisation and (re)starting ART and have C-reactive protein (CRP), interleukin-6 (IL-6) and D-dimer measured (available at randomisation for the majority of SMART participants and a selected group from FIRST who participated in previous biomarker studies). Using random effects linear models, we assessed the association between each of the biomarker levels, categorised as quartiles, and change in CD4 from ART-start to 24 months post-ART. Analyses adjusted for pre-ART CD4, study arm, follow-up time and other known confounders. Sensitivity analyses included separate analyses by trials (given it was a selected sub-sample in FIRST) and excluding the DC arm in SMART.

Results: Overall, 1084 individuals (659 from SMART (26% ART naïve) and 425 from FIRST) met the eligibility criteria, providing 8264 CD4 measurements. 75% were male with the mean age of 42 years, 37% and 47% were white and black respectively, and 10% and 33%, respectively, were hepatitis B and C positive. The median (inter-quartile range) baseline CD4 (cells/mm^3) were 360 (265-473) overall and 416 (350-530) and 100 (22-300) in SMART and FIRST, respectively. All of the biomarkers were inversely associated with baseline CD4 in FIRST but not in SMART. The figure shows the mean change in CD4 post-ART by quartiles of CRP, IL-6 and D-dimer. In adjusted models, there did not appear to be any clear relationship between changing biomarker levels and mean change in CD4 (P for trend: CRP: 0.97; IL-6: 0.25 and D-dimer: 0.29). Sensitivity analyses yielded similar results.

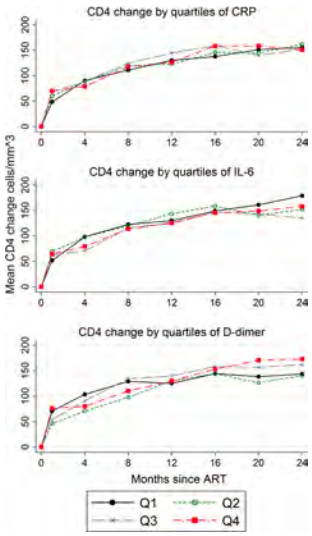

Figure: Change in CD4 count since (re)initiation of ART by pre-ART quartiles of CRP, IL-6 and D-dimer. Q=quartile (e.g. Q1= 1st quartile etc.).

Conclusions: Pre-ART inflammation/coagulation activation do not predict CD4 response to ART and appear to influence the risk of clinical outcomes through mechanisms other than by blunting long-term CD4 gain.

316 Plasma Levels of sCD163 Predict All-Cause Mortality From HIV Infection

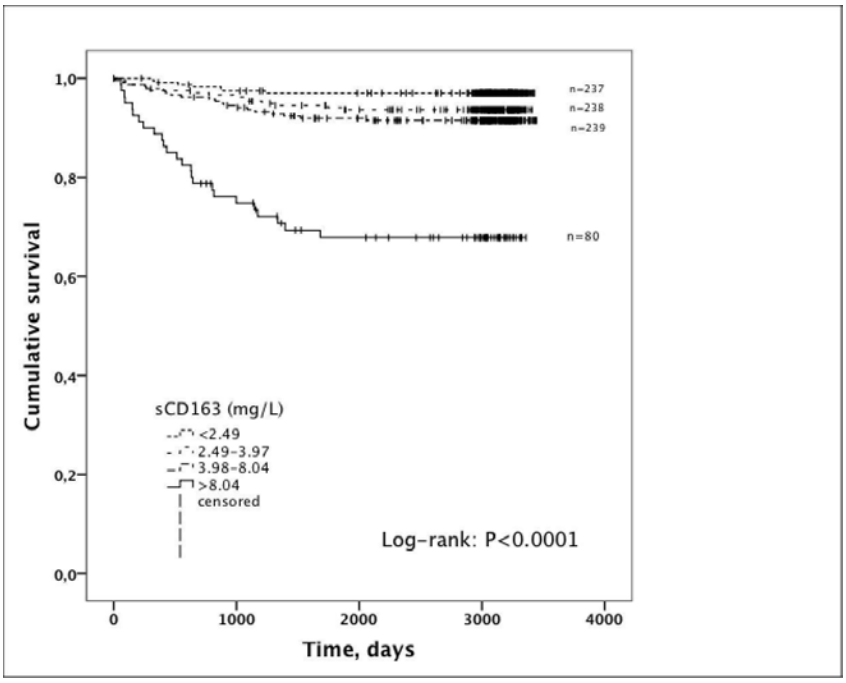
Troels Bygum Knudsen[1]; Janne Petersen[2]; Holger Jon Møller[3]; Søren Moestrup[4]; Jesper Eugen-Olsen[2]; Gitte Kronborg[1]; Thomas Benfield[1]

[1]Copenhagen University Hospitals, Hvidovre, Copenhagen, Denmark; [2]Copenhagen University Hospitals, Hvidovre, Copenhagen, Denmark; [3]Aarhus University Hospital, Aarhus, Denmark; [4]Aarhus University, Aarhus, Denmark

Background: CD163, a monocyte- and macrophage-specific scavenger receptor, is shed from the cell surface as soluble CD163 (sCD163) during activation. Monocyte/macrophage activation may contribute to on-going low-grade inflammation in human immunodeficiency virus (HIV)-infected patients. We therefore investigated the role of monocyte activation by measuring sCD163 levels in relation to outcome from HIV infection.

Methods: Plasma sCD163 levels were measured in 794 individuals with HIV infection in 2004/5. The prognostic value of sCD163 was evaluated by Cox proportional hazards regression analysis after adjustment for other risk factors. Kaplan-Meier survival curves were constructed for 0-30, 31-60, 61-90 and 91-100 percentiles. All values are median and interquartile range.

Results: Individuals were 42 (IQR: 37-50) years old and 72% were male. 43% were men who had sex with men (MSM), 36% were heterosexuals (HSX) and 15% injection drug users (IDU). 86% were receiving antiretroviral treatment (ART). Baseline CD4 T cell count was 502 (348-705) per μl and HIV RNA <20 (<20-87) copies/mL. Plasma sCD163 was 3.39 (2.27-5.07) mg/L. During 8.4 (8.1-8.8) years of follow up, there were 67 deaths (8.4%). Individuals who died had significantly higher sCD163 levels than survivors. In adjusted analysis, the mortality increase per mg of sCD163 was 8% (Hazard rate (HR): 1.08, 95% confidence interval (CI): 1.05-1.12). Age (HR: 1.07 (95% CI: 1.05-1.10) per year increment) and IDU vs. no IDU (HR: 2.30 (95% CI: 1.27-4.15) were other independent predictors of death while higher CD4 T cell counts (HR: 0.18 (95% CI: 0.09-0.37) per log increment) were associated with a decreased risk of death. In time-updated analysis, ART did not affect outcome (HR: 1.32 (0.59-2.95). The top 10% group of sCD163 had a 5-fold increased risk of death compared to the lowest 30% group (HR: 5.75 (95% CI: 2.20-15.02) (Figure 1).



Conclusions: The study verifies a clear association between the scavenger receptor system of macrophages and survival in HIV-infected individuals suggested by previous studies. It is the first to demonstrate a highly significant increase in mortality among HIV-infected individuals with an excessive activation of their monocyte/macrophage system. Our findings show that sCD163 is a novel prognostic marker and suggest that monitoring monocyte/macrophage activation may be important in HIV infection.

317 Immunologic Pathways That Predict Mortality in HIV+ Ugandans Initiating ART

Sulggi A. Lee[1]; Helen Byakwaga[2]; Yap Boum[2]; Tricia Burdo[3]; Yong Huang[1]; Jessica Haberer[5]; Annet Kembabazi[2]; David R. Bangsberg[5]; Jeffrey Martin[1]; Peter W. Hunt[1]

[1]University of California San Francisco, San Francisco, CA, US; [2]Mbarara University of Science and Technology, Mbarara, Uganda; [3]Boston College, Boston, MA, US; [4]University of California San Francisco, San Francisco, CA, US; [5]Massachusetts General Hospital and Harvard University, Boston, MA, US

Background: Abnormal immune activation persists in most HIV-infected individuals despite prolonged antiretroviral therapy (ART)-mediated viral suppression, and predicts increased morbidity and mortality, but the specific immunologic pathways predicting disease remain incompletely defined, particularly in resource-limited settings. Plasma kynurenine/tryptophan (KT) ratio, a marker of indoleamine 2,3-dioxygenase-1 (IDO) activity, strongly predicts mortality in this setting, but whether it is simply a marker for other immunologic pathways is unclear.

Methods: We sampled the first 542 HIV-infected Ugandans initiating ART in the UARTO cohort and measured plasma KT ratio, D-dimer, IL-6, sCD163, sCD14, and T cell activation (%HLA-DR+CD38+) at baseline and month 6 of ART-mediated viral suppression (<400 copies/ml). Predictors of mortality were assessed with Cox proportional hazards models, adjusted for age, body mass index, and pre-ART CD4+T cell count.

Results: Participants were mostly female (70%) with a median age of 34, and had advanced disease (median baseline CD4+ count 140 cells/mm^3 and HIV RNA 5.0 $\log_{10}$copies/mL) at ART initiation. A total of 43 deaths occurred during a median 7 years of follow-up, with just 10% LTFU at 7 years. As previously reported, both pre-ART and month 6 KT ratio predicted increased mortality. In addition, pre-ART D-dimer, IL-6, and sCD14 were associated with increased mortality in unadjusted and adjusted models. After 6 months of ART-mediated suppression, IL-6 and sCD14 remained significant predictors of mortality, but CD4+ and CD8+ T cell activation were associated with even greater risks of death. However,

further adjustment for KT ratio rendered mortality associations with all other biomarkers non-significant. The association between KT ratio and mortality persisted despite adjustment for all other biomarkers, with the possible exception of IL-6 at month 6 (HR 1.75, 95% CI 1.00, 3.01).

Biomarker	Pre-ART aHR (95% CI)[a]	Pre-ART + KT Ratio Adjustment	Month 6 ART aHR (95% CI)[a]	Month 6 ART +KT Ratio Adjustment
KT ratio (log_{10}nM/uM)	**1.98 (1.34, 2.91)**	--	**2.26 (1.38, 3.68)**	--
Pre-ART CD4+ count (cells/mm^3)	**0.39 (0.22, 0.69)**	**0.40 (0.22, 0.72)**	0.34 (0.11, 1.04)	0.45 (0.16, 1.32)
D-dimer (log_{10}ug/mL)	**2.36 (1.56, 3.56)**	**2.21 (1.44, 3.39)**	1.69 (0.91, 3.13)	1.52 (0.75, 3.07)
IL-6 (log_{10}pg/mL)	**1.73 (1.36, 2.18)**	**1.66 (1.28, 2.15)**	**1.98 (1.28, 3.06)**	1.63 (0.99, 2.67)
sCD163 (log_{10}ug/L)	0.95 (0.62, 1.46)	0.79 (0.52, 1.20)	1.32 (0.67, 2.59)	0.89 (0.42, 1.92)
sCD14 (log_{10}ug/L)	**2.33 (1.41, 3.84)**	**1.79 (1.00, 3.20)**	**1.97 (1.09, 3.57)**	1.46 (0.75, 2.84)
CD4+ T cell activation	1.14 (0.63, 2.03)	0.92 (0.52, 1.64)	**2.54 (1.21, 5.35)**	1.62 (0.77, 3.41)
CD8+ T cell activation	1.26 (0.76, 2.09)	1.09 (0.65, 1.81)	**2.64 (1.26, 5.56)**	1.97 (0.94, 4.15)

[a] Per interquartile range increase, adjusted for age, BMI, and pre-ART CD4+ T cell count. [b] Per interquartile range increase, adjusted for age, BMI, pre-ART CD4+ T cell count, and log_{10}KTratio. *Abbreviations: ART, antiretroviral therapy; BMI, body mass index; CI, confidence interval; aHR, adjusted hazard ratio per interquartile range increase; IL-6, interleukin-6; KT ratio, ratio of kynurenine to tryptophan; sCD163, soluble CD163; sCD14, soluble CD14.*

Conclusions: The immunologic pathways predicting mortality among HIV-infected Ugandans may be different than those described in resource-rich settings. IDO and T cell activation may have a greater impact during early ART in resource-limited settings where opportunistic infections remain an important cause of death. These findings also suggest that monocyte (sCD14) and T cell activation may predict mortality via the same causal pathways as IDO, while IL-6 may predict mortality via overlapping but potentially distinct pathways.

318 Immune Activation Impairs Yellow Fever Vaccine Efficacy in HIV-Infected Patients

Vivian I. Avelino-Silva[1]; Karina T. Miyaji[1]; Marisol Simoes[2]; Marcos Freire[2]; Ana Sartori[1]; Peter W. Hunt[3]; Karine Milani[1]; Augusto Mathias[1]; Ana Paula Batista[1]; Esper G. Kallas[1]

[1]University of Sao Paulo Medical School, Sao Paulo, Brazil; [2]Fundaçao Oswaldo Cruz, Rio de Janeiro, Brazil; [3]University of California San Francisco, San Francisco, CA, US; [4]University of Sao Paulo Medical School, Sao Paulo, Brazil

Background: While highly immunogenic in healthy vaccinees, Yellow Fever vaccine (YFV) induces weaker and less durable immune responses in HIV-infected individuals. Chronic immune activation may impair cellular and humoral responses to YFV in HIV-uninfected individuals, but little is known about the immunologic predictors of YFV response in HIV infection. We enrolled HIV-infected and –uninfected adults who received YFV to evaluate predictors of immunity, as assessed by specific neutralizing antibody (NAb) titers.

Methods: 18-65 year-old volunteers who received a single YFV dose despite time since vaccination were eligible. All HIV-infected participants were ART-suppressed. Participants with diabetes, chronic liver, renal, or rheumatologic diseases, or prior cancer (except Kaposi Sarcoma) or immunosuppressive therapy were excluded.

Results: Among 34 HIV-infected and 58 HIV-uninfected participants, median age was 46 and 38 years old, respectively, and more HIV-infected volunteers were men (79% vs. 29%). Median time since YFV was somewhat shorter in HIV-infected (42 months) than in HIV-uninfected participants (69 months). Few participants in either group recalled adverse events after YFV. Compared to HIV-uninfected controls, HIV-infected participants had lower median $CD4^+$ T cell counts (790 vs.1120/mm^3, p<0.0001) and $CD4^+/CD8^+$ ratios (0.69 vs. 1.83, p<0.0001). Mean log_{10}NAb titers were also significantly lower in HIV-infected than HIV-uninfected participants (3.3 vs. 3.6, p=0.044), a difference that remained significant after adjustment for age, gender, and time since vaccination (p=0.024). In HIV-infected participants, lower NAb titers were associated with longer time since YFV (rho: -0.38, p=0.027) and lower $CD4^+/CD8^+$ ratio (rho: 0.42, P=0.014), but not $CD4^+$ T cell count (p=0.519). None of these factors were associated with NAb titers in HIV-uninfected participant.

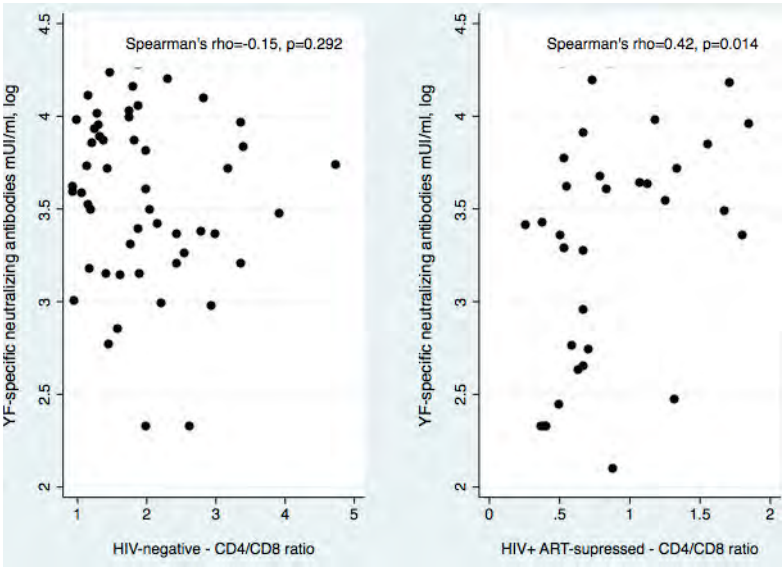


Figure 1: Relationship between CD4/CD8 Ratio and YF Neutralizing Ab Titer in HIV-infected and –uninfected Participants.

Conclusions: Treated HIV-infected individuals appear to have impaired and/or less durable neutralizing antibody responses to YFV than HIV-uninfected individuals, which were associated with lower $CD4^+/CD8^+$ ratio. These results suggest that a low $CD4^+/CD8^+$ ratio may be a better surrogate for functional immune defects than the $CD4^+$ T cell count in treated HIV infection. Our findings are consistent with an emerging literature suggesting that $CD4^+/CD8^+$ ratio is a stronger correlate of chronic immune activation and predictor of mortality in this setting.

319 Association Between sCD163 and CMV IgG in Virologically Suppressed HIV+ Patients

Aimee Hodowanec[1]; Brett Williams[1]; Barbara Hanson[1]; Britt Livak[2]; Sheila Keating[3]; Nell Lurain[1]; Oluwatoyin M. Adeyemi[4]

[1]Rush University Medical Center, Chicago, IL, US; [2]University of Chicago, Chicago, IL, US; [3]Blood Systems Research Institute/University of California San Francisco, San Francisco, CA, US; [4]Ruth M Rothstein CORE Center, Chicago, IL, US

Background: HIV+ patients with controlled viremia have ongoing chronic inflammation which has been associated with an increased risk for cardiovascular and neurocognitive disease. Cytomegalovirus (CMV) has been implicated as a potential driver of this inflammation. Soluble CD163 (sCD163) is a marker of monocyte/macrophage activation and is upregulated in inflammatory states. We explore the relationship between CMV and sCD163 in HIV+ pts with well controlled viremia.

Methods: Patient samples and data from existing cohorts of HIV+ subjects with undetectable HIV RNA were utilized for this study. Specimens were collected between 2009 and 2013. ELISA was used to measure sCD163 level in plasma and CMV immunoglobulin G (IgG) level in serum. All subjects underwent plasma CMV PCR testing. Bivariate analysis (Pearson Correlation and Kruskal Wallis Test) and multivariate linear regression analysis were performed to identify variables associated with CMV IgG level. Variables included in the multivariate model are sex, race, age, duration of antiretroviral use, and sCD163 level.

Results: Of 139 adult, virologically suppressed HIV+ subjects, 130 (94%) were CMV seropositive and were included in our analysis. The median age was 55 (51-59) years, 63% male, 61% black, 18% Hispanic, 12% white, and 2% other race. The median CD4 count was 512 (193-696) cells/mm^3, median sCD163 was 1171.3 ng/mL (886.7-1554.1), and median CMV IgG level was 39.0 IU/mL (32.0-46.0) (results reported as median (IQR) unless stated otherwise). No subjects had detectable plasma CMV DNA. Bivariate analysis revealed a significant, positive correlation between sCD163 and CMV IgG levels ($r = 0.19$, $p = 0.03$) and a trend towards increased CMV IgG among those with coronary disease ($H = 2.99$, $p = 0.08$). Multivariate analysis also identified a positive relationship between CMV IgG levels and sCD163 (coef. 0.004; 95%CI 0.001-0.003 $p = 0.01$).

Conclusions: Among HIV+ adults with undetectable HIV RNA, increased CMV IgG level (even in the absence of CMV viremia) is associated with increased sCD163 level. Our finding adds to the body of evidence suggesting that CMV is involved in the complex pathophysiology of chronic inflammation in HIV. Cellular correlates of these elevated CMV IgG levels deserve further exploration.

Manipulating Immune Activation

320 The mTORC1 Inhibitors, Temsirolimus and Everolimus, Suppress HIV Patient-Derived CD4+ T-Cell Death and Activation In Vitro

Clovis S. Palmer[1]; Matias Ostrowski[4]; Jingling Zhou[1]; Linda Lam[1]; Alan Landay[2]; Anthony Jaworowski[1]; Joseph M. McCune[3]; Suzanne M. Crowe[1]

[1]Burnet Institute, Melbourne, Australia; [2]Rush University Medical Center, Chicago, IL, US; [3]University of California San Francisco, San Francisco, CA, US; [4]Instituto de Investigaciones Biomédicas en Retrovirus y SIDA, Buenos Aires, Argentina

Background: Activated T cells support their energetic and biosynthetic demands in part by increasing glucose uptake and glycolysis. Glucose transporter 1 (Glut1), the major glucose transporter on T cells, is essential for CD4+ T cell activation and effector functions, and its expression is increased on CD4+ T cells in HIV-infected subjects. High Glut1 expression on CD4+ T cells is associated with immune activation/inflammation and low CD4 cell count, irrespective of treatment status. We hypothesized that experimental inhibition of glycolysis in activated CD4+ T cells would inhibit HIV-induced cell death and supress the production of inflammatory mediators.

Methods: Flow cytometry was used to examine Glut1 expression on CD4+ T cells from 58 virologically supressed HIV+ males (viral load <50 RNA copies/ml), 40 immunological responders (median CD4: 700), 18 immunological non-responders (median CD4: 246), and 29 HIV- male controls. Glut1-expressing CD4+ T cells ($CD4_{Glut1}$) were sorted on a FACSAria machine. Glycolytic inhibition was achieved using the mTORC1 inhibitors, temsirolimus or everolimus. Cell death was measured by a trypan blue exclusion. Secreted L-lactate levels served as a measure of glycolytic activity and cytokine levels were determined by ELISA.

Results: The proportion of $CD4_{Glut1}$ cells was significantly elevated in immunological non-responders (median: 14.8, IQR: 11.7-36.9, $p<0.0001$) compared to responders (median: 8.4, IQR: 5.4-12.3) and HIV- controls (median: 4.9, IQR: 1.6-6.9, $p<0.0001$). $CD4_{Glut1}$ cells purified from HIV+/ART subjects underwent more rapid cell death in culture compared to CD4+ T cells not expressing Glut1. The in vitro death of both CD4+ T cell populations was markedly reduced when co-cultured with non-toxic concentrations of the temsirolimus or everolimus. Remarkably, both drugs at a concentration as low as 1 nM effectively suppressed glycolysis by 25-50% in CD4+ T cells that were activated *in vitro* with PMA and IL-2, with effects persisting beyond 7 days after exposure. Further, temsirolimus suppressed CD4+ T cell activation (as measured by HLA-DR expression) and TNF secretion by approximately 20 and 75%, respectively.

Conclusions: High glycolytic metabolism may be associated with accelerated CD4+ T cell death in HIV+ persons. These data suggest that periodic addition of the clinically safe mTORC1 inhibitors, temsirolimus or everolimus, to current ART regimen may reduce residual T cell activation and inflammation, and improve T cell recovery.

321 Decreased Monocyte Activation With Daily Acyclovir Use in HIV-1/HSV-2 Coinfected Women

Andrew D. Redd[1]; Kevin Newell[2]; Eshan U. Patel[1]; Fred Nalugoda[3]; Paschal Ssebbowa[3]; Sarah Kaliballa[3]; Ronald H. Gray[4]; Thomas C. Quinn[1]; David Serwadda[5]; **Steven J. Reynolds**[1]

[1]National Institute of Allergy and Infectious Diseases (NIAID), Washington, DC, US; [2]Clinical Research Directorate/Clinical Monitoring Research Program, Leidos Biomedical Research, Inc., Frederick National Laboratory for Cancer Research, Frederick, MD, US; [3]Rakai Health Sciences Program, Kalisizo, Uganda; [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, US; [5]Makerere University College of Health Sciences, Kampala, Uganda

Background: In two separate randomized control trials, acyclovir treatment of HSV-2/HIV coinfected individuals significantly reduced HIV viral load, and decreased the rate of disease progression. It is unclear if the protective effect of acyclovir use on HIV disease is a direct effect of decreasing HIV replication, or a secondary effect of decreased immune activation associated with less herpetic reactivation.

Methods: HIV-1/HSV-2 co-infected women from the Rakai Health Sciences Program, Uganda were enrolled in a double-blind randomized placebo-controlled trial to examine the effect of daily acyclovir use on HIV disease progression. Serum samples were collected at enrollment and every six months for two years (n=301).

High sensitivity CRP and sCD14 levels were measured on all available serum samples. Longitudinal analyses of treatment outcome were right-censored at initiation of HAART for those women who started therapy. The predictive value of CRP and sCD14 on survival was estimated using Kaplan-Meier survival curves and Cox proportional hazard regression models. Mixed-effects models were used to examine time varying CRP and sCD14 levels by study arm.

Results: Higher baseline levels of sCD14 were not associated with progression to HAART eligibility when adjusted for treatment arm, baseline CD4, and viral load. Higher CRP levels were also not predictive of disease progression. Levels of CRP increased in both arms, and were not significantly different (p=0.25). Levels of sCD14 decreased slightly in both arms, but at a significantly increased rate in the treated women (-0.003 $\log_{10}$ sCD14/month, 95% CI=-0.005- -0.002) compared to the placebo group (-0.001 $\log_{10}$ sCD14/month, 95% CI=-0.002-0.001; p=0.02), which was independent of HIV viral load and CD4 count (p=0.039). However, the decrease in sCD14 in the treatment group was small with a total change in levels of 0.072 $\log_{10}$ (290 ng/mL) over the two-year period, which is 15% of the mean sCD14 levels at baseline in the treatment group.

Conclusions: sCD14 levels decreased faster in the acyclovir treated arm than in the placebo arm independent of CD4 count and viral load. These data support the hypothesis that decreased monocyte activation may contribute in part to the slower HIV disease progression observed during daily acyclovir treatment.

322 Atorvastatin Reduced T-Cell Activation and Exhaustion Among Suboptimal Immune Responders: A Randomized Crossover Placebo Controlled Trial

Damalie Nakanjako

Makerere University Infectious Diseases Institute, Kampala, Uganda

Background: T-cell activation independently predicts mortality, poor immune recovery and non-AIDS illnesses during combination antiretroviral therapy (cART). Atorvastatin showed anti-immune activation effects among HIV-infected cART-naïve individuals. We hypothesized that adjunct atorvastatin therapy would reduce T-cell activation among cART-treated adults with suboptimal immune recovery.

Methods: A randomized double-blind placebo controlled cross-over trial, of atorvastatin 80 mg daily versus placebo for 12 weeks, among individuals with CD4 increase <295cells/μl after seven years of suppressive cART. Change in CD4 T-cell-activation (CD3+CD4+/CD8+ CD38+HLADR+) and CD8 T-cell-activation and in T-cell-exhaustion (CD3+CD4+/CD8+PD1+) were measured using flow cytometry.

Results: Thirty patients were randomized, 15 to each arm. Atorvastatin resulted in a 28% greater reduction in CD4 T-cell-activation (60% reduction) than placebo (32% reduction); p=0.001. Atorvastatin also resulted in a 35% greater reduction in CD8-T-cell-activation than placebo (49% versus 14%, p=0.0009), CD4 T-cell exhaustion (27% versus 17% in placebo), p=0.001, and CD8 T-exhaustion (27% versus 16%), p=0.004. There was no carry-over/period effect. Expected adverse events were comparable in both groups and no serious adverse events were reported.

Conclusions: Atorvastatin reduced T-cell immune activation and exhaustion among cART-treated adults in a Ugandan cohort. Atorvastatin adjuvant therapy should be explored as a strategy to improve immune recovery during antiretroviral therapy.

323 P2X Type Purinergic Antagonists Can Block HIV-1 Infection and Associated Inflammation

Talia Swartz; Meagan O'Brien; Anthony Esposito; Nina Bhardwaj; Benjamin Chen

Icahn School of Medicine at Mount Sinai, New York, NY, US

Background: HIV-1 causes a chronic, incurable infection that is associated with chronic inflammation. Even in the face of virologic suppression with antiretroviral therapy this inflammation can persist. The mechanism of this inflammation is not clearly understood. Purinergic receptors are known to be mediators of inflammatory responses and can contribute to pro-inflammatory cytokine production and lymphocyte cell death. Purinergic receptor signaling has been found to be important for HIV-1 infection and we have recently found that inhibition of the P2X subtype purinergic receptors potently blocks HIV-1 productive infection at the level of membrane fusion. This study examines whether virus-induced purinergic signaling is responsible for inflammatory cytokine release during HIV-1 infection.

Methods: Our laboratory has developed methods using fluorescent constructs of HIV-1 to evaluate productive infection by flow cytometry and confocal microscopy. Infected supernatants can be subjected to multiplex bead capture assays to test for an array of human cytokines including IL-12, IL-10, IL-8, IL-6, TNF, and IL-1β. We have tested the effect of HIV-1 infection on peripheral blood mononuclear cells and observed levels of pro-inflammatory cytokine production.

Results: We observe that HIV-1 productive infection in CD4 T lymphocytes is potently blocked by P2X selective inhibitors. We further observed that exposure of peripheral blood mononuclear cells to HIV-1 results in induction of pro-inflammatory cytokines including IL-1β and IL-6 and that these levels are reduced with P2X inhibition. This suggests that P2X inhibitors can block both HIV-1 productive infection and associated inflammation.

Conclusions: Our findings distinguish P2X receptors as key signaling mediators of HIV-1 infection and inflammation. Studies in progress will examine the mechanism of P2X signaling in HIV-1 entry and will test whether purinergic antagonists can block HIV and reduce inflammatory sequelae of HIV-infection in humanized mouse models. We are exploring whether these drugs could be used as adjunctive antiretroviral therapy that could serve to reduce the morbidity and mortality associated with HIV-1 chronic inflammation.

Pathogenesis in Lymph Nodes

324 CD4$^+$ T cell death mediated by pyroptosis in early SIV infected lymphatic tissues

Wuxun Lu[1]; Guobin Kang[1]; Fangrui Ma[1]; Yanmin Wan[2]; Yue Li[1]; Mark Lewis[3]; Qingsheng Li[1]

[1]*University of Nebraska-Lincoln, Lincoln, NE, US;* [2]*Shanghai Public Health Clinical Center and Institutes of Biomedical Sciences, Fudan University, Shanghai, China;* [3]*BIOQUAL, Inc., Rockville, MD, US*

Background: Lymphatic tissues are the principle sites for HIV-1 replication, host-virus interaction and CD4$^+$ T cell loss. However, the current understanding of the virus-host molecular interaction in lymphatic tissues, especially in early infection, is limited. We thus investigated virus-host interaction in the lymph nodes (LNs) of rhesus macaques during early simian immunodeficiency virus (SIV) infection.

Methods: Sixteen adult male macaques were intra-rectally inoculated with SIVmac251 (3.1 x 10^4 $TCID_{50}$) and were euthanized at 3, 6, 10, 14 or 28 days post-inoculation (dpi); another 3 macaques were used as uninfected controls. Total RNA was isolated from rectal draining LNs of macaques and whole genome transcriptome was profiled using Illumina GAIIx, and genes with altered expression were identified and analyzed. SIV RNA in rectal draining LNs was quantified by using qRT-PCR and in situ hybridization (ISH). CD4$^+$ and caspase-1$^+$ cells in LNs were quantified using flowcytometry.

Results: SIV RNA was detected in all the animals euthanized at 6 and 10 dpi using both qRT-PCR and ISH, however, SIV RNA was only detected in 2 and 1 out of 3 animals at 3 dpi using qRT-PCR and ISH respectively. Transcriptome analysis showed that hosts had clear responses, with 103, 366 and 1350 differentially expressed genes (DEGs) at 3 dpi, 6 dpi and 10 dpi, respectively. Pathway analysis of DEGs at 6 dpi and 10 dpi pointed to the activation of pyroptosis in addition to innate immune response and inflammation pathways. Multiple genes in pyroptosis pathway were significantly up-regulated in expression. The active form of capase-1, the hallmark of pyroptosis activation, was quantified in $CD4^+$ T cells in rectal draining LNs using flowcytometry. Concurrent with loss of $CD4^+$ T cells in draining LNs after early infection, the level of caspase-1^+ $CD4^+$ T cells significantly increased, indicating that the pyroptosis mediated $CD4^+$ T cell death occurs in vivo in early SIV infected lymphatic tissues.

Conclusions: This study shows robust host responses to early SIV infection, the activation of pyroptosis pathway, and $CD4^+$ T cell loss mediated by pyroptosis in lymphatic tissues in *vivo*. Since $CD4^+$ T cell loss and immune activation are the hallmarks of HIV pathogenesis, the $CD4^+$ T cell loss mediated by pyroptosis and associated immune activation *in vivo* in early SIV infection identified in this study opens a new avenue to design interceptive strategy to prevent $CD4^+$ T cell death.

325 Fibrosis in Lymphoid Tissue Is Associated With Peripheral Blood Regulatory T Cells

Julie C. Gaardbo[1]; Patricia S. Nielsen[2]; Lise Mette R. Gjerdrum[3]; Karoline Springborg[4]; Elisabeth Ralfkiær[4]; Henrik Ullum[4]; Åse Andersen[4]; **Susanne D. Poulsen**[4]
Dr. Susanne D Poulsen, sdn@dadlnet.dk
[1]University of Copenhagen, Rigshospitalet, Copenhagen, Denmark; [2]Aarhus University Hospital, Denmark, Aarhus, Denmark; [3]Bispebjerg Hospital, University Hospital of Copenhagen, Denmark, Copenhagen, Denmark; [4]Rigshospitalet, University of Copenhagen, Copenhagen, Denmark

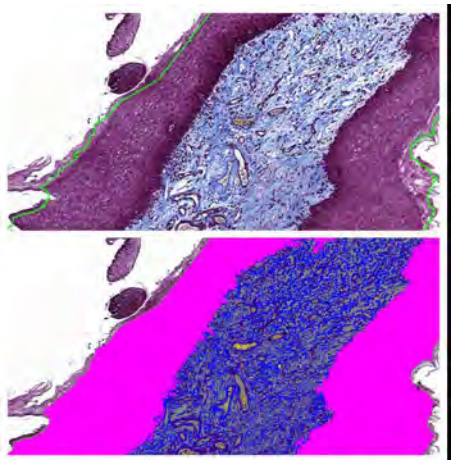
Background: HIV may damage the structure in lymphoid tissue replacing the functional space with collagen. Regulatory T cells (Tregs) have anti-inflammatory properties exerting their function in part by secretion of transforming growth factor beta (TGF-b) which is known to induce fibrosis. In pathogenic SIV infection tissue fibrosis induced by TGF-b1-postive Tregs has been demonstrated. Thus, Tregs may participate in the pathogenesis leading to fibrosis in lymphoid tissue in HIV infection as well. We hypothesized that lymphoid tissue fibrosis was associated with percentage of peripheral blood Tregs and the level of immune activation.

Methods: Tonsil biopsies from 27 HIV-infected patients were examined. All patients had been on cART for a minimum of two years, had CD4 nadir <250 cells/μL, and HIV RNA had been ≤20 copies/mL for at least two years prior to inclusion in the study.

Automated image analysis of tricrome-stained, paraffin-embedded tonsil biopsies determined the amount of fibrosis where $A_{fibrosis}$ was the area of fibrous connective tissue and A_{lesion} the area of the lesion including all tissue elements except epithelia, large lymphocyte clusters, and erythrocytes (see figure).

Based on fibrosis index patients were divided into two groups with low fibrosis (n=13) and high fibrosis (n=14). Tregs (CD4+CD25+$CD127^{low}$FoxP3+) and activated cells (CD4+CD38+HLA-DR+) were determined in peripheral blood using flow cytometry. Differences between groups were analysed using Mann-Whitney U-test. Results are given as median (IQR).

Results: The groups of patients with low fibrosis vs. high fibrosis were similar in regard to age, sex, current CD4 and CD8 cell counts, and CD4 nadir. The group with low fibrosis displayed lower percentage of Tregs compared to the group with high fibrosis (4.8% (4.4-6.9) vs. 6.9% (5.6-8.4), P=0.0186). This was accompanied by lower percentage activated CD4+ cells in low fibrosis vs. high fibrosis (1.5% (1.0-2.2) vs. 2.5% (1.8-4.2), P=0.0319).



Masson tricrome-stained tonsil biopsy and result of automated image analysis. Blue:Fibrous connective tissue; Pink: epithelia; yellow: erythrocytes; purple/grey: other tissue components.

Conclusions: Patients with low amount of fibrosis in tonsil tissue also exhibited low percentage Tregs and immune activation, suggesting Tregs to be involved in the pathogenesis of fibrosis in HIV-infected patients on cART

326 Decreased T_{FR}/T_{FH} Ratio in SIV-Infected Rhesus Macaques

Ankita Chowdhury; Perla Del Río-Estrada; Steven Bosinger; Guido Silvestri
Emory University, Atlanta, GA, US

Background: T follicular helper cells (T_{FH}) are critical for the development and maintenance of germinal centers (GC) and the humoral immune response. During chronic stages of HIV/SIV infection T_{FH} cells accumulate, possibly as a result of antigenic persistence. The SIV/HIV-associated T_{FH} expansion may also reflect a lack of regulation by suppressive follicular regulatory $CD4^+$ T cells (T_{FR}) . T_{FR} cells are natural regulatory T cells (T_{REG}) that migrate into the follicle and, similarly to T_{FH} cells, up-regulate CXCR5, Bcl6 and PD1.

Methods: Lymph node (LN) biopsies were obtained from SIV-infected and uninfected rhesus macaque (RM), as well as HIV-infected humans. T_{FR} cells were identified by flow cytometry and immunohistochemistry. Cell-associated viral DNA was measured by RT-PCR and next-generation RNA sequencing was performed on sorted populations from uninfected and SIV-infected RM by Illumina.

Results: We identified T_{FR} cells as $CD4^+$, $Foxp3^+$, $CXCR5^+$, $PD1^+$ and $Bcl6^+$ within LN of both humans and RM and confirmed their localization within the GC by immunohistochemistry. RNA sequencing showed that T_{FR} cells share a T_{FH} and T_{REG} transcriptional profile with intermediate expression of FoxP3, Bcl6, PRDM1, IL-10 and IL-21. In

healthy, SIV-uninfected RM, we observe a negative correlation between frequencies of T_{FR} cells and both T_{FH} (p=0.0358) and GC B cells (p=0.0140) as well as with levels of $CD4^+$ T cell proliferation (p=0.0315). Following SIV infection, the ratio of T_{FR} to T_{FH} cells was reduced (p=0.0058) with no change in the frequency of T_{REG} cells or in the frequency of T_{FR} cells within the total CD4 T cell pool. Finally, we examined whether higher levels of direct virus infection of T_{FR} cells might be involved in their relative depletion post-SIV infection. We found that T_{FH}, T_{FR} and T_{REG} cells sorted from SIV- infected RM harbor comparable levels of cell-associated viral DNA.

Conclusions: Our data suggests that T_{FR} cells may contribute to the regulation and proliferation of T_{FH} and GC B cells *in vivo* and that a decreased ratio of T_{FR}/T_{FH} cells in chronic SIV infection of RM may lead to unchecked expansion of both T_{FH} and GC B cells.

Dissecting Pathogenesis Through In Vitro Studies

327 A Dual-Tropic HIV-1 Env Interacts With CCR5 to Deplete Bystander CD4 T Cells In Vitro and In Vivo

Li-Chung Tsao[1]; Haitao Guo[2]; Jerry Jeffrey[3]; James A. Hoxie[4]; Lishan Su[2]

[1]*University of North Carolina, Carrboro, NC, US;* [2]*University of North Carolina, Chapel Hill, NC, US;* [3]*GSK, Chapel Hill, NC, US;* [4]*University of Pennsylvania, Philadelphia, PA, US*

Background: Bystander CD4 T cell depletion during HIV-1 infection plays an important role in AIDS disease progression, a process is largely mediated by the HIV-1 Env protein. CCR5 is one of the two co-receptors required for HIV-1 binding and subsequent entry, but its involvement in Env-induced pathogenesis is poorly understood. In this report, we study the CD4 T cell pathogenesis caused by a dual-tropic HIV-1 virus R3A Env, focusing on the role of Env-CCR5 binding.

Methods: Using a cultured PBMC infection model or humanized mice in vivo, R3A can readily induce both infected CD4 T cell death and uninfected "bystander" CD4 T cell death. To study the involvement of Env-CCR5 binding, we utilized an Env-mutant of R3A, termed R3A-5,6AA, which has lost the potential for CCR5 binding.

Results: We found loss of CCR5-binding by the mutant R3A-5,6AA resulted in reduced pathogenesis of bystander CD4 T cells. Importantly, R3A-5,6AA can replicate to the same level as wild type R3A by using CXCR4-binding for virus entry. Accordingly, treatment of CCR5 antagonist TAK-779 inhibited bystander CD4 T cell death in R3A infection without affecting viral replication. In addition, stimulation of CCR5 using MIP1-β in R3A-5,6AA infection increases bystander CD4 T cell death. We have further confirmed our finding in vivo using a humanized mice model, and we observed bystander CD4 T cell pathogenesis in the spleen and bone marrow is dependent on CCR5 usage by the HIV-1 Env.

Conclusions: We provide the first evidence in physiologically relevant in vivo models that shows CCR5 binding by HIV-1 Env plays an important role in Env-induced depletion of bystander CD4 T cells.

328 Investigation of the Association of Gag-Protease Dependent Replication Capacities With Clinical Outcomes of HIV-1 Infection

Keiko Sakai[1]; Takayuki Chikata[1]; Hiroyuki Gatanaga[2]; Shinichi Oka[2]; Masafumi Takiguchi[1]

[1]*Kumamoto University, Kumamoto-shi, Japan;* [2]*National Center for Global Health and Medicine, Tokyo, Japan*

Background: Immune pressure by cytotoxic T lymphocytes (CTLs) induces escape mutations and immune evasion in HIV-1 infection, and the persistence of escape variants shapes HLA-associated viral diversity at the population level. Previous studies with Caucasian and African cohorts showed that HLA-associated Gag polymorphisms impose fitness cost and that Gag-Protease mediated viral replication capacity (Gag-Pro RC) is compromised in patients with protective HLA alleles. However, the protective alleles reported in Caucasian/Africa cohorts, including B*57:01, are not prevalent in Japan. Therefore, factors associated with protection are likely to be different in Asian populations due to different HLA distributions. Moreover, the role of Gag in HIV-1 disease progression has not been well defined in the Asian populations. To address these issues, we investigated HLA-associated changes in Gag-Pro RCs in a Japanese cohort.

Methods: We generated chimeric $HIV\text{-}1NL_{4\text{-}3}$ carrying *gag-protease* derived from 330 treatment-naive Japanese individuals who are chronically infected with HIV-1 subtype B. Replication capacities of chimeric viruses were determined by infecting CEM-GXR cells *in vitro*, which are engineered to express LTR-GFP, CCR5, and CXCR4. Subsequently, we examined the association of Gag-Pro RCs with clinical markers of HIV infection and the impact of patients' HLA alleles on Gag-Pro RCs.

Results: In contrast to Caucasian- and African-cohort studies, patients with higher Gag-Pro RCs showed only a weak tendency toward higher viral load (VL) and lower CD4 count. We did not observe statistically significant associations. Even though previous studies with Caucasian and African cohorts reported a stronger association of Gag-Pro RCs with patients' VL in the presence of protective HLA alleles such as HLA-B*57, our data indicated that subjects who did not carry Japanese-specific protective alleles, HLA-B*52 and -B*67, showed a statistically significant association between Gag-Pro RCs and VL. Furthermore, we found six locations in the Gag-Protease region, four of which was negatively correlated and the other two positively correlated with VL.

Conclusions: Taken together, our data suggested the impact of Gag-Pro dependent replication on HIV-1 disease progression in the absence of a protective immune pressure. The results also implied a different mechanism of HLA-induced changes in Gag-Pro RCs and their impact on clinical outcomes in the Japanese population compared to Caucasian and African cohorts.

329 Association of Bacteria-Induced IL-23 and Th17 Frequencies in HIV-1^+ Individuals

Jennifer Manuzak[1]; Sonia Amraoui[1]; Nipa Decroix[2]; Pierre Loulergue[2]; Odile Launay[2]; Marco Iannetta[1]; Jean-Baptiste Guillerme[1]; Lene Vimeux[1]; Anne Hosmalin[1]

[1]*Inserm U1016, Institut Cochin, Paris, France;* [2]*Centre d'Investigation Clinique CIC 1417, Inserm-AP-HP, Hôpital Cochin, Paris, France*

Background: Cytokine imbalances in HIV-1 infection could be mediated in part by the innate immune response to translocated intestinal microbes. Previous work showed that PBMC from HIV-1-infected patients ($HIV\text{-}1^+$) produce significantly more IL-23 in response to bacterial stimulation as compared to uninfected controls ($HIV\text{-}1^-$). Overproduction of IL-23 could skew T cell responses towards a Th17 phenotype. However, the relationship between microbial translocation, cytokine production and Th17 cell frequencies in the context of *in vivo* HIV-1 infection is not well understood. We compared IL-23 production and the frequency of Th17 cells in response to bacterial stimulation during HIV infection.

Methods: PBMC from 18 chronically infected $HIV\text{-}1^+$ and 21 $HIV\text{-}1^-$ donors were utilized. The frequency of Th17 cells ($IL\text{-}17A^+IFN\text{-}\gamma^-$) within memory $CD4^+$ T cells ($CD3^+CD4^+CD45RA^-$) of total PBMC was assessed either *ex vivo* on fresh PBMC or *in vitro* after stimulation with *E. coli* or *P. aeruginosa* using frozen PBMC by multi-parameter flow cytometry. Levels of IL-23 in PBMC culture supernatants after bacterial stimulation were assessed by ELISA. Statistical significance between the $HIV\text{-}1^+$ and $HIV\text{-}1^-$ groups was assessed using Mann-Whitney tests. Correlations were calculated using Pearson tests.

Results: The frequency of Th17 cells *ex vivo* was significantly increased in HIV-1$^+$ (n=15) as compared to HIV-1$^-$ (n=15; p=0.0001). In preliminary experiments, the median level of IL-23 production in HIV-1$^+$ (n=6) did not reach statistical significance over HIV-1$^-$ (n=6) after *in vitro* stimulation with *E. coli* (p=0.39) or *P. aeruginosa* (p=0.24). However, the correlation between the level of IL-23 production and the frequency of Th17 cells in HIV-1$^+$ was significant after stimulation with *E. coli* (n=6; p=0.01) and *P. aeruginosa* (n=6; p=0.02) stimulation.

Conclusions: We found increased frequencies of peripheral blood Th17 cells in chronic HIV-1$^+$ patients. This may be due to elevated cytokine production in response to translocated bacteria, as suggested by the relationship between IL-23 levels and Th17 frequencies after bacterial stimulation in HIV-1$^+$. Th17 cells are preferentially depleted in the intestinal mucosa of HIV-1$^+$, likely due to infection and killing of these cells. Our data suggest a potential mechanism by which the innate immune response to HIV-1-induced microbial translocation could promote the expansion, activation, viral infection and destruction of Th17 cells in the gut, thus contributing to HIV-1 disease pathogenesis.

330 Effect of Methamphetamine Use on T-Cell Proliferation In Vivo and Ex Vivo

Marta Massanella[4]; Sara Gianella[4]; Jennifer M. Dan[1]; Eric Daar[2]; Michael P. Dube[3]; Richard H. Haubrich[4]; Douglas D. Richman[4]; Davey M. Smith[4]; Sheldon Morris[4]; Rachel D. Schrier[4]

[1]La Jolla Institute of Allergy and Immunology, La Jolla, CA, US; [2]Los Angeles Biomedical Research Institute at Harbor–University of California Los Angeles Medical Center, Torrance, CA, US; [3]University of Southern California Keck School of Medicine, Los Angeles, CA, US; [4]University of California San Diego, La Jolla, CA, US

Background: Methamphetamine (METH) is a widely used recreational drug among HIV-infected men who have sex with men (MSM). Its use is associated with worse health outcomes in HIV-infected individuals. Here we investigated the effect of METH-use on immune function and virus shedding in semen.

Methods: Paired PBMC and semen samples were collected from our *in vivo* cohort of chronically HIV-infected MSM on suppressive ART (n=50, of whom 16 self-reported METH-use). PBMC were analyzed for markers of immune activation (CD38, HLA-DR and CD45RA), proliferation (Ki67) and exhaustion (PD-1) by flow cytometry. Seminal levels of cytomegalovirus (CMV) and HIV were quantified by real-time PCR. *Ex vivo* studies were performed on 19 HIV-infected individuals from a treated, but not uniformly suppressed cohort who tested positive for METH by urine toxicology (UTox+) and 19 HIV-infected UTox negative controls (matched for viral load and CD4 T-cell counts). PBMC proliferative responses to mitogen PHA and to CMV, candida, Mycobacterium tuberculosis, toxoplasma and HIV antigens were assayed in triplicate after 7 days of culture. T-cell proliferation was measured by [^{3}H]-thymidine incorporation; stimulation index was calculated as a ratio of the mean counts per minute (cpm) for each stimulus divided by the mean cpm of unstimulated controls. Mann-Whitney and Fisher exact tests were used for continuous and dichotomous data comparisons, respectively.

Results: METH-users had significantly higher CD4 and CD8 T-cell proliferation levels (Ki67$^+$, p<0.005 for both), CD4 T-cell activation (CD45RA$^-$CD38$^+$, p=0.005) and CD4-T cell exhaustion (PD-1$^+$, p=0.0004) compared to non-METH-users. In addition, the proportion of CMV or HIV shedding in METH-users was higher than in non-METH users (75% vs 26% [p=0.002] and 19% vs 3% [p=0.09], respectively). *Ex vivo* responses of the acute METH UTox+ patients confirmed higher spontaneous PBMC proliferation compared to controls (p<0.05). However, METH UTox+ subjects had significantly reduced proliferation to PHA (p<0.0005) and pathogen antigens (all p<0.04) compared to UTox–.

Conclusions: Our findings suggest that METH-use may activate and exhaust the immune system. Furthermore, METH might reduce the immune response to reactivating or invading pathogens leading to a loss of control of CMV and HIV replication, as suggested by an increase in CMV and HIV seminal shedding in the genital tract. Future studies should consider METH-use as a potential modulator of T-cell responses.

Dissecting Pathogenesis Through In Vivo Studies

331 A Random Forest Approach to Define Immunological Thresholds for CD4 Recovery in HIV-Treated Individuals

Josué Pérez-Santiago[1]; **Marta Massanella**[1]; Dan Ouchi[2]; Elisabet Gómez[2]; Cecilia Cabrera[2]; Bonaventura Clotet[3]; Eugenia Negredo[3]; Julià Blanco[2]

[1]University of California San Diego, La Jolla, CA, US; [2]IrsiCaixa Institute for AIDS Research, Badalona, Spain; [3]LIuita Contra la Sida Foundation, Germans Trias i Pujol University Hospital, Badalona, Spain

Background: The failure to increase CD4 T-cell counts in some ART-suppressed patients has been related to low CD4 T-cell production, high activation and cell death. While some clinical data indicate that low CD4 threshold (i.e. 200 CD4 cells/μL) may have strong impact on survival, the lack of an accepted standard definition of immune recovery hamper a proper clinical follow up and has led to discrepant results among different studies. Our aim is to use a supervised machine learning approach to evaluate different clinical definitions of immune recovery.

Methods: In a cross-sectional, case-control study, 185 participants on suppressive ART (<50 copies/mL for ≥2 years) were evaluated for CD4 T-cell production, immune activation markers, soluble CD14, cell death, clinical and demographical variables. We use random forest classification (R statistical software) to investigate different definitions of immune recovery based on 1) CD4 T-cell counts (using cut-off values ranging from 250 to 600 cells/μL) and 2) CD4 T-cell increase from CD4 nadir value (Delta CD4, using values ranging from 50 to 500 cell/μL). Patients below or above the indicated values were considered as discordant, or concordant respectively.

Results: Among all CD4 cut-off definitions, 400 cells/μL cut-off segregated best concordant vs. discordant individuals with a balanced accuracy of 85%, specificity of 87% and sensitivity of 83%. Most important variables included intrinsic and total apoptosis of CD4 T cells, CD4 nadir, and the frequency of Fas$^+$HLA-DR$^+$ CD4 T cells. When Delta CD4 definitions were used, the best classifier was obtained with an increase of 300 CD4 cells/μl with a balanced accuracy of 79%, specificity of 77% and sensitivity of 81%. Surprisingly, the most important variable for delta CD4 classifications was CD8 absolute count, along with CD4 cell death (total, intrinsic apoptosis and necrosis) and CD4 activation, while CD4 nadir was not an essential defining parameter. Variables previously related to discordance (such as thymic production, time on ART or CD8 T-cell activation) did not show significant importance for any classification.

Conclusions: The 400 cell/μl cut-off definition classified better discordant and concordant patients than Delta CD4 classifications. As expected cut-off classification was strongly associated with destruction and activation of CD4 T cells. However, the gain of CD4 T cells is strikingly associated to CD8 absolute counts, corroborating the use of CD4/CD8 ratio as a measure of immune recovery.

332 Disease Progression in HIV Controllers; Uptake and Outcome of Antiretroviral Therapy

Jane R. Deayton[1]; Katherine C. Groves[2]; David F. Bibby[2]; Duncan A. Clark[2]; Iain Reeves[3]; Jane Anderson[3]; Chloe M. Orkin[4]; Eithne O'Sullivan[1]; Áine McKnight[1]

[1]Barts and the London, Que, London, United Kingdom; [2]Barts Health NHS Trust, London, United Kingdom; [3]Homerton University Hospital NHS Foundation Trust, London, United Kingdom; [4]Barts Health NHS Trust, London, United Kingdom

Background: We have previously reported a cohort of 86 HIV-1 "controllers" and defined a subset, "discord controllers (DC)" with low or declining CD4 counts (<450) despite control of plasma viral RNA. We showed that DCs are distinct both clinical and immunologically, having depletion of naïve CD4 cells and higher activation in all CD4 subsets compared with typical controllers (TC). Data are scarce on clinical management and outcome of controllers so we undertook a follow-up study of the cohort.

Methods: HIV controllers recruited into the prospective cohort were designated DC or TC depending on the geometric mean titre of the last 3 CD4 counts. Controls were HIV non-controllers and uninfected individuals. Baseline HIV-1 DNA load in peripheral blood mononuclear cells was determined by quantitative PCR and expressed as per cell equivalent.

Results: 18 DCs were recruited; 2 are lost to follow-up. DCs had higher DNA loads (13-1529, median 601 copies/10^6 CD4 cells) compared to TCs (0-755, median 87) (p=0.002) and were similar to those in non-controllers (27-2188, median 852). Ten DCs had received 12-66 (median 42) months of antiretroviral therapy (ART). RNA loads were 85-19837 (median 796) at ART initiation and all became undetectable on therapy. However, CD4 gain was modest; from baseline 163-308 (median 272), CD4 change was -25 – +318 (median +130) over follow-up. Those with lower nadir CD4 had lowest CD4 gain despite extended ART. Of 6 ART naïve patients, only one remained undetectable. CD4 counts in the naïve patients were unexpectedly low at 217-464 (median 304). Of note, 5 patients had declined to start ART despite low and declining CD4 counts.

Conclusions: The significantly higher DNA loads in the DC group suggest productive ongoing HIV-1 replication and are compatible with increased immune activation, poor clinical outcomes and sub-optimal CD4 response to ART as described in this, and other, controller cohorts. Initiation of ART occurred late in DCs (some declined treatment), suggesting that both clinicians and patients may feel falsely reassured by low RNA loads in the face of low CD4 counts. These results suggest that controllers may benefit from earlier ART and that clinicians should remain vigilant to this despite low or undetectable RNA loads. In addition, DNA load may be a better marker of viral replication and disease progression than RNA load and may identify controllers in whom early ART is indicated. Ongoing longitudinal follow-up of this cohort is planned.

333 Immunological and Virological Progression in HIV Controllers

Nicolas Noel[1]; Nathalie Lerolle[1]; Camille Lecuroux[2]; Cécile Goujard[1]; Alain Venet[2]; Asier Sáez-Cirión[3]; Véronique Avettand-Fenoel[4]; Laurence Meyer[5]; Faroudy Boufassa[5]; Olivier Lambotte[1]
ANRS CO21/CODEX Study Group

[1]APHP, Service de Médecine Interne et Immunologie Clinique, Hôpital Bicêtre, Le Kremlin-Bicêtre, France, Le Kremlin Bicêtre, France; [2]Inserm U1012, Régulation de la Réponse Immune, Infection VIH1 et Autoimmunité, Le Kremlin Bicêtre, France; [3]Institut Pasteur, Unité de Régulation des Infections Rétrovirales, Paris, France; [4]APHP, Service de Virologie, Hôpital Necker – Enfants Malades, Paris, France; [5]Inserm U1018, Centre de Recherche en Epidémiologie et Santé des Populations, Université Paris Sud, Le Kremlin-Bicêtre, France

Background: HIV controllers (HICs) display spontaneous long-term control of HIV replication. Some HICs show a decline in their CD4 T cell count or lose the ability to control the virus. The aim of this study was to investigate the rate and determinants of immunological and/or virological progressions in a large cohort of HICs.

Methods: HICs from the French ANRS CO21/CODEX study are ART-naive HIV-1-infected patients diagnosed for > 5 years with 5 last consecutive HIV viral loads (VL) < 400 copies/mL. Immunological progression during follow-up was suspected if CD4 T cell count fell < 350/mm^3 or declined by more than 200/mm^3 from a last CD4 count ≤ 600/mm^3. Viral progression was suspected if HIV VL rose > 2000 copies/ml. The events of immunological and virological were confirmed if similar CD4 counts or VL were found on a consecutive measurement. Clinical characteristics were analysed at inclusion in the cohort and prior to the event. Immune activation and inflammatory parameters (% of HLADR+CD38+ T cells, IP10 levels), ultrasensitive HIV VL and total HIV DNA were compared using non parametric tests with the non-progressor HICs.

Results: Out of 217 patients followed in the cohort between 2009 and 2013, 37 patients experienced at least one suspicion of progression. Progression was confirmed in 15 patients (immunological progression, n=10; viral progression, n=5). Compared with non-progressor HICs, viral progressors (VP) were enrolled younger (p<0.01). No differences in terms of HLA B57 status or HCV coinfection were observed. Unprotected sexual intercourse and sexually transmitted infections were reported in the recent history of some HICs, but not more frequently in progressors. Relative to non-progressors, immunological progressors HICs had lower CD4 T cell nadir (median (IQR): 292 (236-373) vs. 516 (412-681)/mm^3, p<0.001), as well as the CD4 count at inclusion, and viral progressors had higher ultrasensitive HIV RNA levels at inclusion (i.e., 1-2 years before progression) (p<0.01 for all). Interestingly, CD8 T cell activation and IP10 levels at inclusion in immunological progressors were significantly higher than in non-progressors (p<0.001), almost as elevated as observed in viremic non HICs patients.

Conclusions: CD4 T cell nadir, level of residual HIV replication and levels of basal immune activation seem major determinants to progression in HICs, and should be considered in order to adjust their follow-up and optimize the timing of cART initiation.

334 HIV Replication History Is Associated With Plasma IL-7 Levels in Aviremic Youths

Daniel Scott-Algara[1]; Jerome Lechenadec[2]; Josiane Warszawski[2]; Thomas Montange[1]; Jean-Paul Viard[3]; Catherine Dollfus[3]; Véronique Avettand-Fenoel[4]; Christine Rouzioux[4]; Stéphane Blanche[3]; **Florence Buseyne**[1]

[1]Institut Pasteur, Paris, France; [2]Inserm, Le Kremlin-Bicêtre, France; [3]AP-HP, Paris, France; [4]Université Paris Descartes, Paris, France

Background: IInterleukin-7 (IL-7) is a key molecule regulating thymopoiesis and peripheral T-lymphocyte proliferation. We previously reported that thymopoiesis was maintained and that naive T cells had high levels of IL-7 high-affinity receptor in both viremic and aviremic youths infected with HIV-1 during the perinatal period. Plasma IL-7 levels were associated with CD4 T-cell count only in viremic patients. Here, we focused on aviremic patients, investigating the factors of HIV disease history associated with plasma IL-7.

Methods: The ANRS-EP38-IMMIP study comprised youths between the ages of 15 and 24 years that had been perinatally infected with HIV and were living in France. Fifty-eight treated patients with < 80 copies of HIV RNA/ml at the time of the study were included in the analysis. T-cell subsets were quantified by flow cytometry. Plasma IL-7 was quantified by ELISA. Univariate and multivariate linear regression analyses were performed.

Results: : Median (interquartile range) plasma IL-7 concentration at the time of the study was 3.9 (2.7-4.6) pg/ml. Higher IL-7 levels were associated with higher cumulative viremia over the last 10 years and higher levels of cell-associated HIV DNA (coefficient [95% CI]: 1.43 [0.20; 2.65] per 10000 days x $\log_{10}$ HIV RNA copies/ml, P=0.02, and 0.77 [-0.03; 1.59] per $\log_{10}$ HIV DNA copies/10^6 PBMCs, P=0.06, respectively). The weak negative correlation between IL-7 levels and CD4 T-cell count was not significant (-0.13 [-0.30; 0.04] per 100 cells/μl, P=0.13). Neither nadir CD4 T-cell percentage nor duration of severe immunosuppression were correlated with IL-7 levels (-0.11 [0.71; 0.49] per 100 cells/μl, P=0.72 and -0.05 [-0.10; 0.20] per year, P=0.53). IL-7 levels were not associated with sex, ethnicity, previous CDC stage C events, HIV-1 subtype or tropism. In multivariate analysis, IL-7 levels were significantly associated with cumulative viremia only (1.26 [0.02; 1.46] per 10000 days x $\log_{10}$ HIV RNA copies/ml, P=0.05). In addition, higher IL-7 levels were associated with lower central-memory CD4 percentage and weaker CD127 expression on this CD4 T-cell subset.

Conclusions: In youths with suppressed HIV viremia, plasma IL-7 levels were associated with exposure to viral replication over the previous 10 years. A similar association was reported with the naive CD4 T cells, consistent with a major impact of past HIV replication on current naive CD4 T-cell homeostasis in patients with perinatally acquired HIV infection.

335 Enhanced Immune Reconstitution With Initiation of ART at HIV-1 Seroconversion (PHI)

Sabine I. Kinloch[1]; Colette Smith[1]; Kwong Tsz-Shan[2]; Jayne Ellis[2]; Margaret Johnson[2]

[1]University College London, London, United Kingdom; [2]Royal Free London NHS Foundation Trust, London, United Kingdom

Background: Early ART initiation has been shown recently to delay the time to AIDS, strengthening the case for early intervention. It is unclear whether immune reconstitution in particular, CD4/CD8 ratio, is enhanced with intervention at Primary HIV Infection (PHI).

Methods: We undertook a retrospective study of a PHI cohort (ART initiation ≤3 months from PHI) from a single center (Royal Free Hospital, London, UK) who had received ≥5 years of continuous ART. The group were compared to a cohort of individuals who started ART at the same center during chronic infection (CI; ≥1 year after diagnosis) with a pre-ART CD4 count>350 cells/mm^3 and who also received ≥5 years(y) of continuous ART. Median CD4 count, CD4%, CD4/CD8 ratio and presence of optimal immune reconstitution (OIR) (CD4≥800 cells/mm^3 or CD4%≥40% or CD4/CD8 ratio≥1) were assessed and compared in the 2 cohorts at 1, 5 and 10y post-ART initiation by considering the measure that occurred closest to the time-point, provided it was ≤6 months. Time to normalization of CD4/CD8 ratio to ≥1 was also assessed using Kaplan-Meier methods.

Results: 37 PHI and 115 CI individuals were included. Median age at time of HIV diagnosis was 34 vs 32 years in the PHI and CI cohorts, respectively. 35 (95%) vs 32 (87%) were male and 32 (87%) vs 84 (73%) were MSM. Median pre-ART nadir CD4 count, CD4% and CD4/CD8 ratios were: 417 vs 313 cells/mm^3; 18% vs 16%, and 0.30 vs 0.29, respectively. Median maximum pre-ART VL were 511,000 (range 3,400, >1.000,000 vs 278,022 (2593, >750,000) copies/mL, respectively.

After 1, 5 and 10 y of ART, median CD4 count, CD4% and CD4/CD8 ratio were significantly higher in the PHI compared to the CI group across all time-points (Table). Similarly, OIR was more common in the PHI group at all time-points. The kinetics of CD4/CD8 ratio showed that the median time to achieving CD4/CD8 ratio≥1 was 36 (95% CI 16-63) weeks in the PHI cohort and 187 (127-204) weeks in the CI cohort (p<0.0001; log rank test).

– Comparison of immunological reconstitution in individuals who start ART during primary infection (PHI) vs in Chronic Infection (CI)

me nce art RT	Median CD4 count (cells/mm^3)			Median CD4%			Median CD4:CD8 ratio			Presence of OIR*		
	PHI	CI	P-value	PHI	CI	P-value	PHI	CI	P-value	PHI	CI	P-value
Year	743	800	<0.0001	35	26	<0.0001	0.95	0.52	<0.0001	51% (19/37)	25% (39/153)	0.002
	850	779	0.005	39	33	<0.0001	1.05	0.78	<0.0001	73% (27/37)	46% (73/158)	0.003
ears												
)	966	874	0.02	38	33	0.01	1.09	0.85	0.04	85% (23/27)	53% (38/72)	0.003

* OIR=optimal immune reconstitution defined by CD4 count =800 cells/mm^3 or CD4% = 40% or CD4:CD8 ratio = 1.00
# 27 patients in PHI cohort had more than ten years of follow-up since treatment initiation

Conclusions: Immunological response to ART in this cohort was excellent, with high median CD4 counts after 10 y of ART. Despite this, ART initiation within 3 months of PHI shows improved immune reconstitution in terms of CD4 T cell count and CD4/CD8 ratio, when compared to a CI cohort initiating ART without severe immunosuppression,. These differences persisted even after 10 years of ART, suggesting damage to the immune system during the early stages of HIV infection can have long-term consequences.

336 cART-Driven Recovery of Immune Function Preferentially Targeting CXCR4-Tropic HIV-1

Joëlle Bader[1]; Martin Däumer[2]; Jürg Böni[4]; Meri Gorgievski[3]; Thomas Klimkait[1]
The Swiss HIV Cohort Study

[1]University of Basel, Basel, Switzerland; [2]Institute for Immunogenetics, Kaiserslautern, Germany; [3]University of Berne, Berne, Switzerland; [4]Swiss National Center for Retroviruses, Zürich, Switzerland

Background: It has been shown that CXCR4-tropic HIV is better neutralized by the immune system than CCR5-tropic variants. Reasons therefore might be the less glycosylated envelope on CXCR4-tropic viruses and the antibody binding due to less steric hindrance. We hypothesize that CXCR4-tropic variants should be better eliminated by a competent immune system generated through efficient cART. Aim of this study was to monitor the frequency of CXCR4-tropic viruses through restoration of the immune system by cART.

Methods: Seventeen patients in the Swiss HIV Cohort Study were followed yearly after virological suppression by tropism testing. All patients were fully suppressed throughout study time and showed good CD4 T cell restoration (>250 cell/mm^3 in 3 years) after cART initiation. For eight we included also three consecutive time points before cART. Frequency of CXCR4-tropic variants was analyzed by Illumina Miseq sequencing (FPR 3.5%, R5 < 2% X4).

Results: Ten patients (59%) had only CCR5-tropic viruses after cART initiation, which stayed CCR5-tropic during follow-up. Of the seven remaining patients with CXCR4-tropic HIV, four (57%) showed decreasing frequencies of CXCR4-tropic variants during therapy. For 15 of the 17 patients we could perform proviral load testing on all time points, four (27%) showed increased proviral loads under therapy. Interestingly, all patients with increasing CXCR4-tropic frequencies had also increasing proviral loads. For four of the seven patients with CXCR4-tropism after therapy we could include tropism data before cART initiation, which showed that all of them had increasing frequencies of CXCR4-tropic viruses with time and without therapy. Two patients of them had even an R5 tropism three years before cART initiation.

Conclusions: We identified a decrease in the frequency of CXCR4-tropic HIV variants under successful cART in the majority of patients in our study. An increase under therapy strictly correlated with increasing proviral loads. We suggest that CXCR4-tropic variants can be better eliminated by the recovering immune system under cART and similarly in early stages of the infection, when immune surveillance is still largely intact. On contrast, weakening of the immune system leads to an increase in CXCR4-tropic viruses. Therefore early therapy initiation and maintaining of an effective immune state might help to better control CXCR4-tropic HIV variants.

337 Repeated injections of r-hIL-7 in HIV Patients receiving ART in INSPIRE 2 & 3 trials

Rodolphe Thiebaut[1]; Ana Jarne[1]; Jean-Pierre Routy[2]; Irini Sereti[3]; Margaret A. Fischl[4]; Prudence Ive[5]; Roberto Speck[6]; Giuseppe Tambussi[7]; Yves Lévy[8]; Michael M Lederman[9]
on behalf of Inspire 2 and Inspire 3 study groups

[1]Bordeaux University, Bordeaux, France; [2]McGill University, Montreal, Canada; [3]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD, US; [4]University of Miami, Miami, FL, US; [5]Wits Health consortium, Johannesburg, South Africa; [6]University Hospital Zurich, Zurich, Switzerland; [7]San Raffaele Scientific Institute, Milano, Italy; [8]INSERM, Paris, France; [9]Case Western Reserve University, Cleveland, OH, US

Background: Phase I/II studies in HIV-infected patients receiving ART have shown that administration of 3 weekly subcutaneous (s/c) injections of Recombinant Human Interleukin 7 (r-hIL-7) is safe and increase numbers of both naive and memory CD4 and CD8 T cells. Here, we report the pooled data from two phase II trials evaluating the effect of repeated cycles of r-hIL-7 with the objective of restoring and maintaining CD4 T cell count over 500 cells/μL.

Methods: INSPIRE 2 was a single arm trial conducted in US and Canada. INSPIRE 3 was a two arm trial with 3:1 randomization to rhIL-7 vs. control conducted in Europe and South Africa. Participants had to be receiving ART with plasma HIV-RNA<50 copies/mL and CD4 T-cell count between 101-400 cells/μL. Patients with chronic hepatitis B or C co-infection or active infections were excluded. R-hIL-7 was administered at 20 μg/kg, in 3 weekly s/c injections per cycle. A repeat cycle was administered if, at any quarterly evaluation, CD4 Tcells fell below 550 cells/μL. In INSPIRE 3, participants randomized to the control arm crossed to receive r-hIL-7 if CD4 cells were below 500 cells/μL at 12 months.

Results: 111 patients were included: 23 in INSPIRE 2 and 88 in INSPIRE 3 including 24 in the control arm. They received one (107), two (74), three (14) or four r-hIL-7 cycles (1) over a median follow-up of 23 months. R-hIL-7 was well tolerated. Four grade 4 events were observed including one asymptomatic ALT elevation. After the induction cycle in INSPIRE 2 and 3 respectively, 6% and 17% developed binding antibodies against IL-7 (neutralizing in 0% and 1%). After the second cycle binding antibodies developed in 82% and 77% (neutralising in 38% and 37%) without impact on the CD4 response. 13% and 17% of patients experienced at any time HIV RNA > 200 copies/mL in INSPIRE 2 and 3, respectively. HIV DNA per CD4 T cells and per PBMC was stable over follow up. The first cycle led to a substantial increase of CD4 T cells, mainly naïve and central memory without expansion of Treg cells. Half the patients spent more than 63% of their follow-up with more than 500 CD4 T cells/μL. The baseline CD4 level was a strong predictor of the probability of staying above 500 CD4 T cells/μL (HR=2.2, p<.0001) whereas there was no difference between the repeated cycles (HR=.99, p=.96).

Conclusions: Repeated cycles of r-hIL-7 were well tolerated and achieved sustained immune restoration over 500 CD4 T cells/μL in the majority of study participants.

338 CRF19_cpx Is an Evolutionary Fit HIV-1 Variant Exclusively Associated With Rapid Progression to AIDS in Cuba

Vivian Kouri[2]; Ricardo Khouri[1]; Yoan Alemán[2]; Yeissel Abrahantes[2]; Nico Pfeifer[3]; Andrea-Clemencia Pineda-Peña[4]; Jorge Pérez[2]; Lissette Pérez[2]; Kristel Van Laethem[4]; **Anne-Mieke Vandamme**[4]
[1]Fundação Oswaldo Cruz, Salvador, Brazil; [2]Instituto Pedro Kouri, Havana, Cuba; [3]Max Planck Institute for Informatics, Saarbrucken, Germany; [4]Katholieke Universiteit Leuven, Leuven, Belgium

Background: Clinicians reported an increasing trend of rapid progression (RP) (AIDS within 3 years of infection) in Cuba.

Methods: Recently infected patients were prospectively sampled, 52 RP at AIDS diagnosis (AIDS-RP) and 21 without AIDS in the same time frame (non-AIDS). 22 patients were sampled at AIDS diagnosis (chronic-AIDS) retrospectively assessed as >3 years infected. Clinical, demographic, virological, epidemiological and immunological data were collected. Pol and env sequences were used for subtyping, transmission cluster analysis, and prediction of resistance, coreceptor use and evolutionary fitness. Host, immunological and viral predictors of RP were explored through data mining.

Results: Subtyping revealed 25 subtype B strains, 6 C, 7 CRF18_cpx, 9 CRF19_cpx, 29 BG-recombinants and other subtypes/URFs. All CRF19 were AIDS-RP. Data mining identified CRF19, oral candidiasis and RANTES levels as strongest predictors of AIDS-RP. CRF19 was more frequently associated with CXCR4 coreceptor use, higher fitness scores in the protease region, and higher viral load at diagnosis.

Patient characteristics Clinical, immunological and virological markers for the non-AIDS, chronic-AIDS and AIDS-RP groups

1) Patient characteristics at HIV diagnosis for the non-AIDS, chronic-AIDS and AIDS-RP groups.				
	non-AIDS (N=21)	**Chronic-AIDS (N=22)**	**AIDS-RP (N=52)**	**p value**
Last negative HIV test before HIV diagnosis (months)	22.0 (10.5-25.0) (N=21)	22.0 (12.0-24.0) (N=22)	14.0 (5.3-23.5) (N=52)	0.17
Log VL at HIV diagnosis (RNA copies/ml plasma)	<1.7 (<1.7-3.5) (N=12)	3.2 (<1.7-3.9) (N=8)	4.8 (4.1-5.4) (N=41)	**<0.0001**
CD4 count at HIV diagnosis (cells per μl blood)	577 (441-815) (N=20)	522 (374-782) (N=22)	276 (152-386) (N=49)	**<0.0001**
Anal sex (as reported by both males and females of various sexual orientation)	80.0% (16/20)	54.6% (12/22)	50.0% (25/50)	**0.031**
Always condom use after diagnosis	45.0% (9/20)	45.5% (10/22)	19.6% (10/51)	**0.016**
Sexual orientation				
Heterosexual	20.0% (4/20)	36.4% (8/22)	49.0% (25/51)	**0.023**
Homosexual	65.0% (13/20)	45.5% (10/22)	41.2% (21/51)	0.087
Bisexual	15.0% (3/20)	18.2% (4/22)	9.8% (5/51)	0.44
2) Clinical, immunological and virological markers at sampling for the three studied groups.				
	non-AIDS (N=21)	**Chronic-AIDS (N=22)**	**AIDS-RP (N=52)**	**p value**
Years elapsed from HIV seroconversion to sampling	1.75 (1.25-2.33) (21)	9.82 (7.97-12.06) (22)	1.40 (0.79-2.16) (52)	-
Log VL at sampling (RNA copies/ml plasma)	3.7 (3.0-4.3) (N=20)	4.7 (4.2-5.4) (N=22)	4.7 (4.0-5.4) (N=47)	**0.0012**
CD4 count at sampling (cells per μl blood)	501 (408-641) (N=17)	212 (113-266) (N=17)	189 (91-225) (N=51)	**<0.0001**
RANTES/CCL5 (pg/ml)	944 (719-1184) (N=18)	1291 (932-1430) (N=21)	1398 (1103-1630) (N=47)	**0.00060**
Co-infections (proportion)				
Oral Candidiasis	4.8% (1/21)	0.0% (0/22)	23.1% (12/52)	**0.013**
HIV subtypes (proportion)				
Subtype B	38.1% (8/21)	40.9% (9/22)	17.3% (9/52)	**0.034**
Subtype C	0.0% (0/21)	4.6% (1/22)	9.6% (5/52)	0.11
CRF18_cpx	9.5% (2/21)	9.1% (2/22)	5.8% (3/52)	0.54
CRF19_cpx	0.0% (0/21)	0.0% (0/22)	17.3% (9/52)	**0.0090**
CRF20,23,24_BG	33.3% (7/21)	22.7% (5/22)	32.7% (17/52)	0.88
Co-receptor use				
X4 (FPR<5%)	0.0% (0/12)	17.7% (3/17)	15.8% (6/38)	0.32
X4-R5X4 (5%≤FPR≤20%)	33.3% (4/12)	29.5% (5/17)	42.1% (16/38)	0.73
R5(FPR>20%)	66.7% (8/12)	52.9% (9/17)	42.1% (16/38)	0.24

1) Patient characteristics at HIV diagnosis for the non-AIDS, chronic-AIDS and AIDS-RP groups. 2) Clinical, immunological and virological markers at sampling for the three studied groups. TDR (transmitted drug resistance): NRTI resistance mutations M41L, F116Y/T215S/K219Q, M41L/T215D and D67N/T215S/K219Q; NNRTI resistance mutations twice K103N and PI resistance mutations N88DN and M46L. Data are expressed as median values with interquartile ranges, or as proportion (%) with number of patients between brackets. Statistical differences between groups were tested using Kruskal-Wallis or Chi-square test for trend. Results were considered significant at p-value<0.05 (displayed in bold). N = number of patients.

Conclusions: CRF19 is a recombinant of subtype D (C-part of Gag,PR, RT and nef), subtype A (N-part of Gag, Integrase, Env) and subtype G (Vif, Vpr, Vpu and C-part of Env). Since subtypes D and A have been associated with respectively faster and slower disease progression, our findings might indicate a fit PR driving high viral load, which in combination

with coinfections may boost RANTES levels and thus CXCR4 use, potentially explaining the fast progression. We propose that CRF19 is evolutionary very fit and causing rapid progression to AIDS in many newly infected patients in Cuba.

The Effect of HIV Infection on B Cells

339 Acute HIV-1 Infection Is Associated With Rapid Changes in B-Cell Subsets and Levels of CXCL13

Jenniffer K. Maroa[1]; Anne-Sophie Dugust[2]; Zelda Euler[2]; Yathisha Ramlakhan[1]; Krista Dong[3]; Bruce Walker[2]; Thumbi Ndung'u[4]; Galit Alter[2]

[1]University of KwaZulu-Natal, Durban, South Africa; [2]Ragon Institute of MIT, MGH and Harvard, Boston, MA, US; [3]Massachusetts General Hospital, Harvard Medical School, Boston, MA, US; [4]HIV Pathogenesis Programme, Durban, South Africa

Background: HIV chronic infection (CI) is characterized by perturbations in B cell homeostasis, phenotype and function. There are limited data describing B cell dynamics during HIV acute infection (AI). Characterizing B cell subsets during AI might help define signatures that shape the humoral response in HIV infection.

Methods: Eleven women who became HIV-1 infected during a longitudinal follow-up study in Durban, South Africa were analyzed. Samples were analyzed at baseline (pre-infection) and weeks 1, 2, 4 and 12 post detection of HIV RNA. Multicolor flow cytometry was used to identify B cell subsets based on expression of CD21CD27 on live CD19+ lymphocytes and defined as follows; activated memory (AM) CD27+CD21-, resting memory (RM) CD27+ CD21+, naïve cells (N) CD27-CD21+, tissue-like memory (TLM) CD27-CD21- and plasmablasts (PBs) CD27+CD38+ cells. Evolution of HIV-specific antibodies and changes in CXCL13 levels were determined by ELISA

Results: Compared to a baseline sample, we observed rapid and significant expansion of TLM cells post HIV infection (PI); 1week ($p = 0.0003$), 2 weeks ($p = 0.0018$), 1 month ($p = 0.046$) and 3 months ($p = 0.043$). In contrast, RM cells were significantly lower throughout AI compared to baseline; 1week ($p = 0.0007$), 2 weeks ($p = 0.016$), 1 month ($p = 0.019$) and 3 months ($p = 0.018$). We observed significant expansion of AM cells at 2 weeks and 1 month ($p = 0.008$, $p = 0.009$ respectively) followed by contraction by 3 months ($p = 0.260$) PI. Peripheral blood PBs peaked by a median of 17 days (range 7-32 days) PI. Changes in B cell subsets were driven by the increase in viral loads. Levels of CXCL13 a chemokine critical for B cell homing to the germinal centers also increased over time in the first 3 months.

Conclusions: Perturbations in B cell subsets and CXCL13 levels occurs immediately following HIV-1 infection and this may therefore determine the subsequent development of anti-HIV antibodies.

340 Bone Marrow Plasma Cells Dictate Serum HIV-Specific Antibodies in Chronic Viremia

Jairo Mauricio Montezuma-Rusca[1]; **Olivia R. Fankuchen**[1]; Lela Kardava[1]; Clarisa M. Buckner[1]; Aaron Louie[1]; Yuxing Li[2]; Tae Wook Chun[1]; Katherine R. Calvo[3]; Susan Moir[1]; Anthony S. Fauci[1]

[1]NIAID/NIH, Bethesda, MD, US; [2]University of Maryland, Rockville, MD, US; [3]NIH Clinical Center, Bethesda, MD, US

Background: Screening for HIV-neutralizing antibody activity in the serum or plasma has been the starting point for the isolation of several potent and broadly neutralizing antibodies to HIV from peripheral blood B cells of infected individuals. Despite the success of this approach, little is known regarding the cells that produce the antibodies detected in the serum. To gain a better understanding of the cellular source of circulating antibodies, we investigated two possible sources, the bone marrow and peripheral blood, of chronically HIV-viremic individuals.

Methods: Bone marrow biopsies and peripheral blood samples were obtained from eight chronically HIV-viremic individuals and bone marrow cells were obtained from eight healthy HIV-negative controls. Written informed consent was provided. Immunophenotyping was performed on cell suspensions using B-cell subset-defining markers. A biotinylated HIV envelope gp140 probe was used to measure HIV-specific antibodies in serum (via ELISA), HIV-specific plasmablasts (via ELISPOT) or memory B cells (via flow cytometry) in blood, and HIV-specific plasma cells in bone marrow (via ELISPOT).

Results: Compared to HIV-negative counterparts, the bone marrow aspirates of the HIV-infected participants contained increased frequencies of plasma cells and B cell precursors (namely preB-I and preB-II), and decreased frequencies of mature B cells. Levels of HIV-specific antibodies measured in serum were compared to corresponding frequencies of antibody-secreting or -binding cells measured in the bone marrow (plasma cells) and the blood (plasmablasts and memory B cells). A strong correlation was observed between HIV-specific antibodies in serum and the HIV-specific bone marrow-derived plasma cells, but not the plasmablasts or memory B cells from blood.

Conclusions: Increased frequencies of plasma cells in the bone marrow are consistent with known hallmarks of HIV infection, namely hypergammaglobulinemia and increased frequencies of peripheral blood plasmablasts. These findings demonstrate that despite HIV-induced phenotypic and functional B-cell dysregulation in the peripheral blood and secondary lymphoid tissues, bone marrow plasma cells remain a primary source for circulating HIV-specific antibodies in HIV-infected individuals.

341 Reduced Expression of Blimp-1 on Memory B Cells in Patients with HIV-1 Infection

Claudia Beisel; Ilona Toth; Jan van Lunzen; Julian Schulze zur Wiesch

University Hospital Hamburg-Eppendorf, Hamburg, Germany

Background: Blimp-1 has long been recognized as master regulator for B cell development and has additionally been recognized as important rheostat, balancing effector function and T cell exhaustion. Although several studies described Blimp-1 in the context of T cell exhaustion in viral infections, the role of Blimp-1 was first and primarily defined as a "master regulator" of terminal B cell development. Blimp-1 attenuates the expression of many transcription factors, thereby inhibiting B cell proliferation and B cell receptor mediated activation while promoting immunoglobulin secretion and plasma cell differentiation. Here, we present novel data describing the expression pattern of Blimp-1 in different B cell memory subsets in a cohort of viremic and treated HIV-1 patients.

Methods: The expression of Blimp-1 in different B cell memory subsets was analyzed by flow cytometry in a cohort of 26 individuals, classified as healthy donors ($n = 7$), treatment naïve HIV-1 infected patients ($n = 9$) and HIV-1 infected patients under antiretroviral therapy (cART) ($n = 10$). B cell memory subsets were defined as activated memory B cells ($CD20^+/CD21^{lo}/CD27^{int}$), tissue like memory B cells ($CD20^+/CD21^{lo}/CD27^-$), resting memory B cells ($CD20^+/CD21^{hi}/CD27^{int}$) and naïve memory B cells ($CD20^+/CD21^{lo}/CD27^{lo}$).

Results: The expression of Blimp-1 on activated memory B cells was significantly down-regulated in patients with HIV-1 infection compared to healthy donors. Viremic, treatment naïve patients showed an even lower expression of Blimp-1 than patients on cART. The relative frequency of Ki67 on activated memory B cells directly correlated with HIV viral load ($p = 0.005$, $r_2 = 0.30$). Additionally, the relative frequency of Blimp-1 on activated memory B cells inversely correlated with HIV-1 viral loads and the relative frequency of Ki67+ activated memory B cells ($p = 0.026$, $r_2 = 0.62$; $p = 0.033$, $r_2 = 0.51$) (Figure 1).

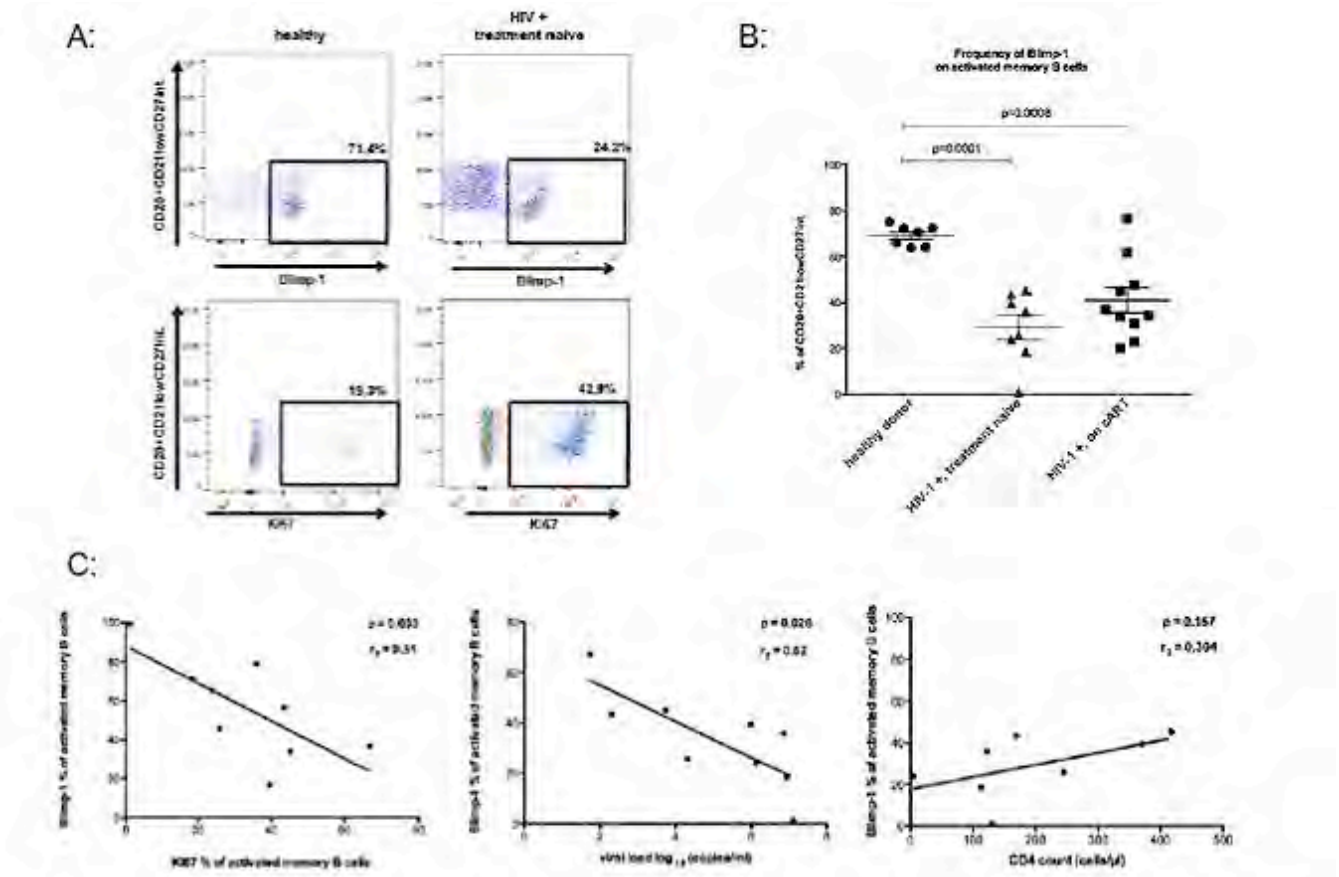

Figure 1: Blimp-1 expression is reduced in HIV-1 infected individuals on activated memory B cells and correlates inversely with HIV-1 viral load and Ki67 expression. (A) Representative fluorescence-activated cell sorter plot showing Blimp-1 and Ki67 expression on activated memory B cells ($CD20^+/CD21^{low}/CD27^{pos}$) in a HIV-1 seronegative individual (left) and a HIV-1 positive, treatment naïve individual (right). (B) Blimp-1 expression is significantly downregulated in HIV-1 positive individuals compared to HIV-1 seronegative individuals. Treatment naïve patients showed an even lower expression of Blimp-1 than patients on cART ($p = 0.0001$; $p = 0.008$). (C) Expression of Blimp-1 correlated inversely with Ki67 expression ($p = 0.033$, $r_2 = 0.51$) and with HIV-1 viral load ($p = 0.026$, $r_2 = 0.61$). Blimp-1 expression did not significantly correlate with CD4+ T cell count ($p = 0.157$, $r_2 = 0.304$).

Conclusions: To our knowledge, this alteration of Blimp-1 expression on activated memory B cells in patients with HIV-1 infection has not been described before. We propose to further investigate the hypothesis whether down-regulation of Blimp-1 expression on activated memory B cells in patients with HIV-1 infection leads to uncontrolled differentiation into antibody secreting cells and consequently to an impaired production of neutralizing antibodies that has been described in HIV infection.

342 Similar or Higher Memory Responses to Influenza Vaccination in Aviremic HIV-infected Patients on Antiretroviral Therapy

Zhenwu Luo; Lisa Martin; J. Michael Kilby; **Wei Jiang**
Medical University of South Carolina, Charleston, SC, US

Background: Potential for recovery of antigen (Ag)-specific B cell functioning after long-term antiretroviral therapy (ART) in HIV-infected patients is not fully understood.

Methods: We examined Ag-specific B cell responses to influenza (flu) vaccine in a cohort of 17 healthy controls and 28 ART-treated aviremic HIV+ patients who received vaccines last year and this year. Blood draws were taken at 0, 7, and 14 days after the latest vaccination. Number of Ag-specific antibody-secreting cells (ASC) were tested by ELISPOT in 0.5 million purified B cells at 0 and 7 days after vaccination. Flu vaccine-specific antibodies (IgM, IgG and IgA) were tested by ELISA in plasma. B cell apoptosis was assessed by flow cytometry.

Results: The median percentages of CD4+ T cell among total CD3+ T cells were 60.32% (IQR 49.64% - 69.32%) and

45.12% (IQR 34.63% - 57.3%), and the median percentages of total CD19+ B cells among all lymphocytes were 7.31% (IQR 5.0% - 9.2%) and 9.2% (6.4% - 11.1%) in controls and patients pre-vaccination, respectively. The frequencies of naïve (CD27-), memory B cells (CD27+) and plasma cells (CD27+CD138+) among B cells were similar in controls and patients pre-vaccination ($P > 0.05$). Ex vivo, apoptosis of naïve B and plasma cells, but not memory B cells, was higher in patients than controls pre-vaccination ($P < 0.05$, Mann Whitney U test). Numbers of flu-specific ASC (IgM and IgA) were low to undetectable at all time points. Number of flu-specific ASC (IgG) in 0.5 million B cells were similar in HIV+ patients and controls before vaccination and at 7 days after vaccination ($P > 0.05$). Ag-specific IgG responses were not related to CD4+ T cell counts at any time point in both controls and patients. Consistently, patients had similar or higher levels of flu-specific IgM, IgG and IgA in plasma pre-vaccination, 7 days and 14 days post-vaccination compared to controls.

Conclusions: Memory responses to influenza vaccination (TD antigen) are recovered in successful HIV virologic suppression after ART treatment even in patients with low CD4+ T cell counts, suggesting that recall responses are independent or much less dependent of CD4+ T cell help.

The Envelope/Antibody Dynamic

343 Estimating and Visualizing HIV-1 Susceptibility to Broadly Neutralizing Antibodies

Anna Feldmann; Nico Pfeifer

Max Planck Institute for Informatics, Saarbrücken, Germany

Background: In HIV-1 treatment, clinicians still have to face drug-resistant viral strains, while the amount of available drugs and drug targets remains limited. Recently, combination therapy with broadly neutralizing antibodies (bNAbs) was introduced as a potential HIV-1 treatment that is capable to reduce viral load under detectable levels for up to 60 days in humanized mice and primates. However, similarly to HAART, the emergence of resistant strains is a major problem when selecting an efficient combination therapy of bNAbs for an individual patient. Prior to the administration of a bNAb combination therapy to a patient, it has to be ensured that the patient's viral strains are susceptible to the particular bNAb.

Methods: For seven different bNAbs we trained a classifier for each using support vector machines. The prediction models are able to determine the neutralization susceptibility of unseen viral strains to the specific bNAb based on the viral envelope sequence (Env). Different string kernels as well as the polynomial kernel and the Gaussian RBF kernel were tested by 10 times nested cross-validation. In addition, we introduce new visualization techniques (e.g., motif of most important residues) to increase model interpretability of non-linear classifiers.

Results: Among all considered kernels, the oligo string kernel performed best. High prediction performance could be traced back to learnt discriminant features that are supported by literature. State of the art performance of the classifiers can be seen in the table. For the V3-loop directed bNAbs the N-glycosylation site at position 332 was found as the most discriminant residue for neutralization susceptibility whereas position 334 confers neutralization resistance. The N-glycosylation site at position 160 was identified to be the most discriminant residue for the classifiers targeting the V1/V2 -loop indicating neutralization susceptibility. The classifiers for the CD4 binding site-directed bNAbs recognized different known binding sites to the CD4 molecule on the gp120 Env subunit to be associated with neutralization susceptibility of the viral strains. In addition to the already known epitopes, we also found other discriminant residues that might be interesting for follow-up structural studies.

Epitope	Antibody	AUC
V1/V2-Loop	PG9	0.67 (±0.03)
	PG16	0.71 (±0.03)
CD4bs	VRC01	0.71 (±0.03)
	VRC-PG04	0.69 (±0.04)
V3-Loop	PGT121	0.79 (±0.02)
	10-1074	0.84 (±0.02)
	10-996	0.81 (±0.03)

AUC (area under the curve) performance of each classifier assessed by 10 times 5-fold nested cross-validation.

Conclusions: The good classfier performances motivate their use in the selection of bNAb combination therapy. The robustness of the models implies that models with similar accuracy and interpretability can also be learnt for additional bNAbs.

344 Sequential SHIV-Env Clones With Neutralization Sensitivity for Breadth Development

Manxue Jia; Cecilia Cheng-Mayer; Xueling Wu

Aaron Diamond AIDS Research Center, New York, NY, US

Background: Neutralizing antibodies gradually increase in breadth in selected SHIV-infected rhesus macaques (RMs) and HIV-1-infected humans. However, the envelope (Env) clones that are responsible for the development of neutralization breadth have not been identified.

Methods: Because the SHIV-RM is the best available animal model for HIV-1 antibody studies, we screened 13 viremic RMs that were intra-rectally infected with the R5 clade B $SHIV_{SF162P3N}$ for neutralization activity against eight HIV-1 heterologous strains. Two animals, GB40 and FF69, were identified as containing the best neutralization breadths and titers. Using plasmas collected longitudinally from these animals, we tested four homologous Env clones derived from the $SHIV_{SF162P3N}$ inoculum and identified two sequential homologous neutralization activities (waves) prior to a third wave that cross-neutralized the tested HIV-1 strains. Based on the time when each wave appears, we selected time points for Env isolation. Full-length *env* sequences were obtained by single genome amplification, and representative *env* clones were tested for neutralization.

Results: From GB40, we obtained 116 *env* sequences and cloned 11 from week 2 (w2), w19 and w35 plasmas, and from the genomic DNA of w13 PBMC. The Env clone w2_1 is sensitive to plasmas from the wave 1 time points (w13 – w19). The Env clone w13_d13 is sensitive to time points between waves 1 and 2, and thus defined a new neutralization activity – wave 1b (w17 – w35). The other isolated GB40 Env clones are not particularly sensitive to wave 2 time points (~w45); therefore, the search for the specific Envs responsible for wave 2 continues. The isolated GB40 Env clones are sensitive to wave 3 time points (w54 and after) when heterologous neutralization is evident. From FF69, we thus far obtained 21 *env* sequences from the peak viremia (w2 plasma) and cloned two major variants, w2_17 and w2_27. Both variants are sensitive to wave 1 time points (w8 – w12) in this animal.

Conclusions: From two $SHIV_{SF162P3N}$-infected RMs, we identified 2-3 sequential waves of homologous responses before the appearance of the heterologous neutralization activity. Examination of sequential Env clones from these animals identified specific Envs with neutralization sensitivity to temporal plasmas in which neutralization specificity gradually broadens. The identification of these Env clones is highly relevant for HIV-1 Env immunogen design.

345 V1V2 Neutralizing Epitopes Are Conserved Within Divergent Groups of HIV-1

Marion Morgand[1]; Mélanie Bouvin-Pley[1]; Craig S Pace[2]; David Ho[2]; Pascal Poignard[3]; Marie Pancera[4]; Jean-Christophe Plantier[5]; Francois Simon[6]; Martine Braibant[1]; Francis Barin[7]

[1]Université de Tours, Inserm U966, Tours, France; [2]Aaron Diamond AIDS Research Center, The Rockefeller University, New York, NY, US; [3]Department of Immunology and Microbial Science, The Scripps Research Institute, La Jolla, CA, US; [4]Vaccine Research Center, NIAID, NIH, Bethesda, WA, US; [5]Université de Rouen, CHU Charles Nicolle, Rouen, France; [6]Laboratoire de Virologie, Hôpital St Louis, Paris, France; [7]Université de Tours, Inserm U966, Laboratoire de Bactériologie-Virologie, CNR du VIH, CHU Bretonneau, Tours, France

Background: HIV-1 has been classified into 4 groups: M, N, O and P. These last years, highly potent broadly neutralizing monoclonal antibodies (bNabs) have been obtained from individuals infected by HIV-1 group M variants. The aim of this study was to analyze the cross-group neutralization potency of these bNabs using a large panel of non-M primary isolates (PI).

Methods: The sensitivity to neutralization of 16 non-M HIV-1 PIs (12 O, 2 N, 1 P, 1 M/O recombinant) was analyzed in a neutralization assay using TZM-bl cells. Twenty two HuMoNabs were used. VRC01, VRC03, 3BNC117 and five clonal variants of NIH45-46^{G54W} target the CD4 binding site (CD4bs). PG9, PG16, PGT145 and PG9-PG16-RH target the N160 glycan-V1V2 site. PGT121, PGT128 and 10-1074 target the N332 glycan-V3 site. 2F5, 4E10 and 10E8 target the MPER of gp41. 8ANC195 target a complex epitope spanning both Env subunits. Two bispecific antibodies that combine the inhibitory activity of an anti-CD4 with that of PG9 or PG16 (BibNabs) were included in the study (PG9-iMab and PG16-iMab).

Results: Cross-group neutralization was observed only with the bNabs targeting the N160 glycan-V1V2 site. Four group O PIs, one group N PI and the group P were neutralized by PG9 and or PG16 at low concentrations (0.04-0.9.39 μg/mL). None of the non-M PIs was neutralized by the bNabs targeting other regions at the highest concentration tested (10 μg/mL), except 10E8 that neutralized weakly two group O PIs (3.35-3.69 μg/mL). The BibNabs neutralized very efficiently all the non-M PIs with IC50 below 1 μg/mL, except two group O strains. The high potency of the BibNabs was mediated by the gp120-binding activity of PG9 and PG16 scFVs.

Conclusions: The N160 glycan-V1V2 site is the most conserved neutralizing site within the four groups of HIV-1. It makes it a potentially interesting target for development of HIV vaccine immunogens. The corresponding bNabs could be useful for immunotherapeutic strategies in patients infected by non-M variants.

346 Improving Neutralization Potency and Breadth by Combining Broadly Reactive HIV-1 Antibodies Targeting Major Neutralization Epitopes

Rui Kong[1]; Mark Louder[1]; Kshitij Wagh[2]; Robert Bailer[1]; Kelli Greene[3]; Hongmei Gao[3]; Michel Nussenzweig[4]; Bette Korber[2]; David Montefiori[3]; John Mascola[1]

[1]Vaccine Research Center, NIAID, NIH, Bethesda, MD, US; [2]Los Alamos National Laboratory, Los Alamos, NM, US; [3]Duke University Medical Center, Durham, NC, US; [4]The Rockefeller University, New York, NY, US

Background: The isolation of broadly neutralizing HIV-1 monoclonal antibodies (mAb) to distinct epitopes on the viral envelope glycoprotein (Env) provides the potential to use combinations of mAbs for prevention and treatment of HIV-1 infection. The potency and breadth of mAb combinations have not been well characterized.

Methods: Two sets of combiantions were tested for neutralization breadth and potency on 125 viruses in TZM-bl assay. Set I includes VRC07 (CD4bs), PG9 (V1V2-glycan), PGT128 (V3-glycan) and 10E8 (MPER). Set II substituted VRC07 and PGT128 with 3BNC117 and 10-1074. In each set, 6 double, 4 triple and 1 quadruple mAb mixtures were made by combining mAbs at equal concentration. To study the interaction of mAbs, the experimental IC50 titers were compared to the titers predicted based on additive model.

Results: All combinations showed substantially improved neutralization breadth and potency compared to the corresponding single mAbs. At an IC_{50} cutoff of 1 μg/ml, VRC07 neutralized 83% of viruses, representing the best coverage by a single mAb, while double combinations neutralized 89-98%, and all triple and quadruple combinations neutralized 98-100%. IC50 and IC80 heat maps showed that a positive antibody in the mix enabled neutralization of strains that were resistant to the negative antibody in the mix, suggesting that the complementary neutralization profiles of the individual mAbs contributed to the improved breadth. When the experimental IC50 titers were compared to IC50 predicted based on additive model, an overall less than two fold differences were observed for all combiantions, suggesting no substantial synergy or antagonism. In 15 out of 22 combinations, including all double and triple combinations with CD4bs, V1V2-glycan and MPER mAbs, small but statistically significat increases were observed in experimetnal titers when compared to the additive prediction.

Conclusions: All 22 double, triple and quadruple combiantions containing mAbs targeting CD4bs, V1V2 glycan, V3 glycan and MPER epitpes showed substaintially improved neutralization breadth and potency. Overall the improvement was closely predicted by additive effect model and explained by complementary neutralization profiles of single mAbs. Subtle but consistent favorable interactions were observed in some mAb combinations.

347 Improved Antibody Cross-Neutralizing Activity in HIV-1 Dual-Infected LTNP Patients

Maria Pernas[1]; Concepción Casado[1]; Victor Sanchez-Merino[2]; Alberto Sanchez-Merino[2]; Isabel Olivares[1]; eloisa Yuste[2]; Cecilio Lopez-Galíndez[1]

[1]Instituto de Salud Carlos III, Majadahonda, Spain; [2]Institut d'Investigacions Biomediquès, Barcelona, Spain

Background: HIV-1 infected individuals, classified as long-term non-progressors (LTNP), remain healthy for many years in absence of antiretroviral therapy, with stable CD4+ T lymphocyte counts and low levels of viral replication. Neutralization studies in sera from LTNPs with undetectable viremia, showed little neutralizing activity (Nab) because of a reduced antigenic stimulation of B cells. A broad NAb response has been associated with prolonged high-levels of antigenic stimulation, in terms of high viral load and viral diversity. In fact, patients infected with two different HIV-1 viruses showed enhanced heterologous NAb response. However, little is known about the neutralizing response in LTNP patients with dual infection (DI) .

Methods: Four DI versus 6 single-infected LTNP patients were compared in their Nab response. Both groups were matched according to years after HIV-1 diagnosis, viral loads and T CD4+ cell counts. NAb response in samples from DI versus single-infected patients, were tested in two samples. A fixed 1/200 serum dilution was tested against a previously described mini-panel of six recombinant viruses from 5 different subtypes and tropisms; Nab breadth, expressed as number of subtypes crossed, was analyzed. To investigate if broader Nab response was related to the viral diversity generated by the DI, diversity in the viral quasispecies was measured by calculating the Shannon Entropy.

Results: LTNP DI patients showed a Nab response (median of 3.0 ± 0.8) significantly ($p = 0.0018$) broader than single-infected patients (median of 1.1 ± 1.1). Association between the number of subtypes crossed and viral diversity (Shannon entropy) showed a high positive correlation ($p = 0.0022$, $r^2 = 0.071$). The median Shannon entropy value of the viral population was statistically ($p = 0.0011$) higher in DI (0.0775) than in single-infected (0.0150) patients, suggesting that the higher viral diversity due to DI was associated with a broader NAb response.

Conclusions: This study analyzed for the first time the neutralization breadth in LTNP patients dually-infected by HIV-1. The higher diversity within the quasispecies generated by HIV-1 DI has contributed to the improvement of neutralization breadth in LTNP patients. These results could be very useful for HIV research and vaccine strategies.

348 Characterization of CD4 Independent HIV-1 Envelope as Potential Immunogens

Lifei Yang[1]; Bradley Cleveland[1]; Andrea P. Jordan[2]; Patricia Polacino[1]; James A. Hoxie[2]; Shiu-Lok Hu[1]

[1]University of Washington, Seattle, WA, US; [2]University of Pennsylvania, Philadelphia, PA, US

Background: We reported earlier that removal of a highly conserved N-linked glycan N197 (N7) on the primary HIV-1 isolate 89.6 improved the immunogenicity of the envelope (Env) protein. Deletion of this glycan made the 89.6 Env more sensitive to CD4-binding site-specificantibodies (Abs) and less dependent on the CD4 receptor to initiate infection. However, it is not clear if the improvement in immunogenicity of 89.6 Env is related to the N7 glycan site mutation per se or the acquisition of a partial CD4i phenotype.

Methods: Here, we generated fully CD4i viruses derived from the WT and the N7 mutant of SHIV 89.6 and isolated Env clones that are replication competent in CD4-negative cells. CD4-independece was confirmed by evaluation of cloned Envs in cell fusion assay and on infectious viruses when cloned back into SHIV backbone.

Then we generated recombinant vaccinia viruses expressing CD4i 89.6WT (i89.6WT) and N7 (i89.6N7) mutant Envs. Antigenicity of these Envs on cell surface was analyzed using flow cytometry. Neutralization sensitivity of CD4i SHIV viruses was tested on TZM-bl cells. Biological function of these CD4i 89.6 Envs was tested by cell fusion assay.

Results: We isolated two i89.6 WT Env clones (A2 and B1) and one i89.6N7 Env clone (D4t), which were derived, respectively, from WT and N7 versions of SHIV 89.6. i89.6 N7-D4t Env maintains an intact CD4 binding site (bs), but CD4bs of i89.6-A2 and -B1 Envs are mutated. Cytoplasmic tails of all three Envs are truncated. In contrast to parental 89.6 WT and N7 Envs, i89.6 WT and N7 Envs can medicate cell-cell fusion in CD4-negative CCR5- and/or CXCR4-expressing cells. Only SHIV i89.6 WT and N7 viruses replicate in those CD4-negative cells.

Recombinant vaccinia viruses expressing i89.6 WT and N7 were generated. Full length i89.6WT and N7 Envs can be expressed, glycosylated and processed into gp120 and gp41. i89.6WT and N7 Envs expressed by vaccinia virus vectors mediate cell fusion and exhibit antigenic properties expected of native Env trimers. They preserve epitopes of most broadly neutralizing Abs tested, but they also show altered antigenicity compared to parental Envs.

Conclusions: Acquisition of the CD4i phenotype is accompanied by changes in the receptor/coreceptor binding properties of the Env and its antigenicity. How these changes may impact the immunogenicity of Env is being examined.

349 Phenotypic Neutralization Sieve Analysis of an SIV Nonhuman Primate Vaccine Challenge Study

Fang-Hua Lee[1]; Brandon F. Keele[3]; Robert Doms[1]; George M. Shaw[1]; Mario Roederer[2]; **Katharine J. Bar**[1]
[1]University of Pennsylvania, Philadelphia, PA, US; [2]Vaccine Research Center, NIAID, NIH, Bethesda, MD, US; [3]National Cancer Institute, Frederick, MD, US

Background: We previously characterized the neutralization sensitivity of the nonhuman primate (NHP) challenge stock SIVsmE660 and found the isolate was generally highly neutralization sensitive with a minor population of resistant variants (Lopker *et al*., J Virol 2013). We hypothesized that incomplete vaccine-mediated protection may result from protection against only the neutralization sensitive fraction of SIVsmE660. Subsequently, a large NHP vaccine study demonstrated incomplete protection from SIVsmE660 challenge and identified genotypic signatures associated with neutralization resistance (Roederer *et al*., Nature 2014). Here, we perform a phenotypic neutralization sieve analysis of the breakthrough TF viruses of this NHP vaccine study.

Methods: TF Env clones were derived by single genome sequencing of peak plasma vRNA from the breakthrough infections in heterologous Env-immunized animals (n=18 TF Envs) and controls (n=35 TF Envs). Neutralization sensitivity was assessed in a TZM-bl assay with SIV-infected macaque plasmas and a panel of 10 monoclonal antibodies (mAb) targeting V1, V2, V3, V4, CD4bs and CD4i epitopes.

Results: The breakthrough TF Envs from immunized animals were significantly more neutralization resistant to immune plasma and mAbs targeting diverse gp120 epitopes than those from control animals. The maximum reductions in infectivity from plasma were 74.6% in control Envs, and 40.3% in vaccine Envs ($p<0.0001$, Mann-Whitney). The majority of vaccine TF Envs (13/18, 72%) were highly neutralization resistant (IC50<1:10), compared with the fraction comprising the control TF Envs (6/35, 17%, $p=0.0002$) and the SIVsmE660 isolate (10%, $p=0.0002$). The genotypic signatures of resistance identified in the Roederer study were highly predictive of phenotypic neutralization sensitivity.

Conclusions: We demonstrate a phenotypic neutralization sieve effect in a large NHP vaccine challenge study with substantial enrichment for neutralization resistant viruses in the breakthrough infections of vaccinated animals. These findings support our hypothesis that incomplete vaccine-mediated protection results from selection against the highly neutralization sensitive component of the SIVsmE660 isolate. Further, we corroborate the genetic signatures of SIVsmE660 neutralization sensitivity predicted in the parent study. Together, these findings demonstrate proof-of-concept that phenotypic neutralization sieve analyses may be useful in assessment of vaccine trial outcomes and correlates analysis.

350 AvFc, a Novel Fc Fusion Protein Targeting Env High-Mannose Glycans

Nobuyuki Matoba; Adam Husk; J. Calvin Kouokam; Krystal Hamorsky; Tiffany Grooms-Williams; Garima Mahajan
University of Louisville James Graham Brown Cancer Center, Owensboro, KY, US

Background: AvFc is a recombinant fusion protein consisting of the high-mannose glycan-binding lectin Avaren and the Fc region of a human IgG1. We have previously shown that AvFc exhibits sub to low-nanomolar neutralization activity against a broad spectrum of HIV-1 and -2 primary strains and HCV genotypes. The objective of this study is to investigate the feasibility of AvFc for use in HIV prevention and/or treatment.

Methods: Combinations of AvFc and other HIV inhibitors were evaluated in HIV-1 neutralization assays. Surface plasmon resonance (SPR) and flow cytometry were used to analyze binding characteristics of the Fc region of AvFc. FcγRIIIa receptor activation was analyzed using an Env-expressing and a Jurkat reporter cell lines. Flow cytometry, multiplex cytokine assay and quantitative PCR were used to test inflammatory potential in human peripheral blood mononuclear cells (PBMC). Rabbit and mouse vaginal irritation models were used to assess vaginal toxicity, while mice and rats were used to examine immunogenicity and systemic toxicity, respectively.

Results: AvFc exhibited synergism with Tenofovir, Maraviroc and VRC01 (combination index << 0.8, CalcuSyn software) against multiple HIV-1 strains. AvFc bound to FcγRI, FcγRIIIa, FcRn and C1q with affinities similar to those of human IgG_1. Furthermore, the FcγRIIIa activation assay indicated that AvFc is capable of inducing antibody-dependent cell-mediated cytotoxicity. Unlike concanavalin A, AvFc had little cytotoxicity, mitogenicity or proinflammatory activity in human PBMC up to 100 μg/ml, which is >1,000 times median anti-HIV IC_{50}. In addition, AvFc did not induce any discernible toxic or inflammatory effects in both vaginal models. Repeated injection of Avaren with an adjuvant did not elicit any significant anti-Avaren IgG response in mice, which is indicative of low immunogenicity; being a small protein (12.5 kDa) with three tandem sequence repeats, Avaren may contain few, if any, T cell epitopes. A single intravenous infusion of 4 mg/kg AvFc in rats did not show any sign of toxicity; no weight loss or behavioral change was observed. Additionally, the complete blood count and serum chemistry of terminal blood samples appeared to be normal.

Conclusions: Our data suggested that AvFc is a unique anti-HIV agent exhibiting broad HIV-neutralizing activity and Fc-mediated functions, and appears to be safe for mucosal and/or systemic administration.

351 DARPins as Entry Inhibitor Alternative to HIV-1 Broadly Neutralizing Antibodies

Emanuel Stiegeler; Nikolas Friedrich; Thomas Reinberg; Mylène Morin; Yufan Wu; Jonas V. Schaefer; Peter Rusert; John Robinson; Andreas Plückthun; Alexandra Trkola
University of Zurich, Zurich, Switzerland

Background: Development of drugs that share the properties of broadly neutralizing antibodies (BNAbs) is highly desirable. Here we utilize the Designed Ankyrin Repeat Protein (DARPin) technology to generate HIV-1 inhibitors with broad neutralization activity directed against the V3 loop. DARPins, small synthetic binding proteins with high target affinities and specificities, have interesting properties as anti-HIV inhibitors in particular as they can recognize their target in a structure dependent manner (Mann A, J Virol 2013).

Methods: V3 specific DARPins were selected from 1st and 2nd generation high diversity molecular DARPin libraries, the latter featuring additional randomized positions in the binding surface and a higher overall stability of the DARPin scaffold. Recombinant gp120 and a structurally arrested V3 epitope mimetic were used as panning targets during

ribosome display selection rounds. The resulting sub-libraries were screened by binding ELISA and pseudovirus neutralization assay. Epitopes were mapped by alanine-scan and characterized by competition ELISA.

Results: Focusing selection of DARPins on the V3 loop using a structurally arrested V3 mimetic proved to be successful. The selected DARPins varied in their binding preference for specific V3 structures and most importantly, showed different degrees of neutralization breadth. As the panning targets were of subtype B origin, the neutralization activity of DARPins was mostly restricted to this subtype. This was improved using the 2nd generation DARPin library, from which we selected a novel type of V3 DARPin with broad neutralization capacity. DARPin 13.2 G10 neutralizes 62.5% of pseudoviruses out of 32 viruses from 5 different clades.

Conclusions: The structurally arrested V3 mimetic proved to be a valuable tool to focus the selection of DARPin clones to V3 and to derive a broadly active entry inhibitor. This result opens novel opportunities for selecting HIV-1 inhibitory DARPins specific for different epitopes.

New Approaches to Immunostimulation

352 Use of Pre-ART-Adjusted Endpoints in the Analysis of an HIV Therapeutic Vaccine Trial

Yunda Huang[1]; Lily Zhang[1]; Darren Jolliffe[3]; Arnt-Ove Hovden[4]; Mats Okvist[4]; Pantaleo Giuseppe[2]; Maja A. Sommerfelt[4]

[1]Fred Hutchinson Cancer Research Center, Seattle, WA, US; [2]Lausanne University Hospital, Lausanne, Switzerland; [3]S-cubed Biometrics Ltd, Oxfordshire, United Kingdom; [4]Bionor Pharma ASA, Oslo, Norway

Background: In one of the largest randomized, double-blind, placebo-controlled phase 2 therapeutic HIV vaccine clinical trials, Vacc-4x was found safe, well-tolerated and immunogenic. While on combination antiretroviral therapy (cART), 135 HIV-infected participants (vaccine: placebo = 92: 43) were randomized and received 4 weekly immunizations followed by booster immunizations at weeks 16 and 18. At week 28, cART was interrupted for up to 24 weeks. Based on the primary analyses, Vacc-4x did not significantly reduce the proportion of participants resuming cART or change in CD4 counts during the cART interruption. We assessed the vaccine effect based on additional exploratory endpoints.

Methods: All analyses included per-protocol (PP) participants who received the full immunization and underwent cART interruption. Linear regression models were used to identify predictors of outcomes measured after cART interruption, and to estimate the vaccine effect adjusted for potential baseline confounding factors. We assessed vaccine effect based on four novel preART-adjusted clinical endpoints: fold changes in CD4 counts at week 40 or in the geometric mean of CD4 counts at weeks 48 and 52 over preART CD4 counts, and fold changes in viral load (VL) at week 40 or in the geometric mean of VL at weeks 48 and 52 over preART VL. We used a multiple imputation approach to account for missing CD4 counts or VL due to cART resumption or dropout.

Results: PreART CD4 counts and VL were significant predictors of levels after cART interruption. A significant vaccine effect was observed in the analysis of all four preART-adjusted endpoints. Compared to the placebo recipients, the vaccine recipients had a higher fold change in week 40 CD4 counts (vaccine vs. placebo mean fold-change difference = 0.08; 95% CI 0.02, 0.15; p=0.02), a higher fold change in weeks 48/52 CD4 counts (0.07; 95% CI 0.01, 0.13; p=0.03), a lower fold change in week 40 VL (-0.46; 95% CI -0.88 to -0.04; p=0.03), and a lower fold change in weeks 48/52 VL (-0.44; 95% CI -0.86, -0.02; p=0.04).

Conclusions: These exploratory analyses consistently suggested that Vacc-4x provided improved effect on preART-adjusted clinical endpoints for CD4 counts and VL over participants' preART conditions. Future HIV therapeutic vaccine studies may adopt similar endpoints of fold changes over preART values to account for participants' heterogeneity and to increase the statistical power of vaccine effect evaluations.

353 Decreased HIV-Specific T-Regulatory Responses Mark Effective Vaccine-Induced Immunity

Vedran Brezar[1]; Nicolas Ruffin[1]; Laura Richert[2]; Mathieu Surenaud[1]; Christine Lacabaratz[1]; Karolina Palucka[3]; Rodolphe Thiebaut[2]; Jacques Banchereau[1]; Yves Lévy[1]; Nabila Seddiki[1]

[1]Inserm U955 (Eq16)-UPEC-VRI, Créteil, France; [2]Univ Bordeaux-ISPED-Inserm U897-VRI, Bordeaux, France; [3]Ralph M. Steinman Center for Cancer Vaccines–Baylor Institute for Immunology Research, Dallas, TX, US

Background: The role of regulatory T cells (Tregs) in vaccination has been poorly investigated. We have reported that vaccination with *ex vivo*-generated dendritic-cells (DC) loaded with HIV-lipopeptides (LIPO-5-DC vaccine) in HIV-infected patients was well tolerated and highly immunogenic. However, patients responded differently to vaccination. Here we hypothesized that the presence and/or induction of HIV-specific Tregs might explain this observation.

Methods: Fourteen HIV-1 infected individuals under effective antiretroviral therapy have been included in this study. Patients received LIPO-5-DC vaccine every 4 weeks during 16 weeks period. Blood was drawn prior (week -4) and after (week 16) vaccination. This was followed by analytical treatment interruption (ATI) at week 24 to measure the magnitude of viral rebound. To assess the antigen-specific effectors (Teffs) and Tregs responses, a novel assay was used in which coexpression of CD25 and CD134 reveals these cells after stimulation *in vitro*. CD39 and FoxP3 markers were used to delineate antigen-specific Tregs and distinguish them from effector specific- responses.

Results: Median LIPO-5-specific $CD25^+CD134^+$ polyfunctional T cells increased from 0.1% (IQR 0-0.3) before vaccination (week -4) to 2.1% (IQR 1.1-3.9) at week 16 following 4 immunizations (P=0.001) and were inversely correlated with viral replication following ATI (r=-0.71, p=0.006). The frequency of LIPO-5-specific Tregs prior to vaccination was elevated, accounting for a median 69.3% (IQR 55.8-75.2) of LIPO-5-specific response. After vaccination, the frequency of HIV-specific Tregs decreased (from 69.3 at week -4 to 31.7% at week 16) and inversely correlated with the HIV-specific IFNγ-producing cells (r=-0.64, P=0.002). These Tregs are highly suppressive as their depletion prior to stimulation led to a further increase in IFNγ responses. Vaccinees who displayed lower levels of LIPO-5-specific $CD4^+CD134^+CD25^+CD39^+FoxP3^+$ Tregs responded better to the vaccine as indicated by a negative correlation between LIPO-5-specific Tregs and post-vaccination immune score.

Conclusions: We show that DC-vaccine skewed the HIV-specific response from regulatory to effector phenotype. Patients with lower magnitude of viral replication following ATI presented lower levels of HIV-specific Tregs. This underlies the role these cells play in HIV-infection and the necessity to take them into account for future vaccine trials.

354 Viral Reservoir Dynamics After Therapeutic Vaccination and cART Interruption

Cristina Andres[1]; Carmen Alvarez-Fernandez[1]; Nuria Climent[1]; Teresa Gallart[1]; Montserrat Plana[1]; Agathe Leon[1]; Nicolas Chomont[2]; Jose M. Gatell[1]; **Felipe Garcia**[1]; Sonsoles Sanchez-Palomino[1]

[1]Hospital Clinic, Barcelona, Spain; [2]Vaccine and Gene Therapy Institute, Port St Lucie, FL, US

Background: We reported a decrease viral set-point of 1.2 log10 associated with an increase in HIV-1–specific T cell responses in HIV infected individuals receiving autologous myeloid derived dendritic cells (MDDC) pulsed with autologous heat-inactivated whole HIV. Here, we assessed changes in viral reservoirs during vaccinations and the dynamics of viral reservoir replenishment during cART interruption after immunizations.

Methods: 36 patients on cART were randomized to 3 immunizations with MDDC pulsed with HIV-1 (n=24) (cases) or with non-pulsed MDDCs (n=12) (controls). Virus for pulsing was isolated 56 weeks before the first immunization during a first cART interruption (STOP 1). Thereafter, cART was reinitiated and after 48 weeks 3 immunizations were performed and cART was interrupted again (STOP2). We measured total and integrated HIV-1 DNA in isolated CD4 T cells before any cART, before STOP1 (preSTOP1), before and after vaccination (VAC1 and VAC2) and at week 12 after second interruption of cART (STOP2). Data are expressed as mean log_{10} copies/10^6 CD4 T cells.

Results: As expected, we observed a drop in total and integrated DNA after the 3 years on cART from the precART period (3.8 and 2.6, respectively) to the time point before STOP1 (3.0 and 1.9, respectively) in the 36 patients ($p<0.0001$ for both comparisons). Three months of cART interruption at STOP1 followed by 9 months of cART did not modify total and integrated DNA in these 36 subjects (VAC1 values: 3.0 and 1.9) ($p=0.41$ and $p=0.62$ as compared with preSTOP1). Vaccination (VAC1 to VAC2 period) did not influence DNA levels in vaccinated subjects (n=24) [total DNA from 2.9 (VAC1) to 2.9 (VAC2), $p=0.86$ and integrated DNA 1.9 (VAC1) to 1.8 (VAC2), $p=0.47$]. After cART interruption post-vaccination (STOP2), while total DNA significantly increased in both vaccinees (n=24) and controls (n=12) (2.9 to 3.3, $p=0.0004$ and 3.2 to 3.7, $p=0.009$, respectively), integrated DNA did not change in vaccinees (1.8 to 1.9, $p=0.22$) and increased in controls (1.8 to 2.1, $p=0.05$). Moreover, these changes in integrated DNA after STOP2 were inversely correlated with changes in HIV specific T cell responses in cases ($r= -0.54$, $p=0.03$), while no correlation was observed in controls ($r= -0.16$, $p=0.74$).

Conclusions: No change in total and integrated DNA was observed after 3 months of cART interruption followed by 9 months of cART. HIV-1 specific immune responses elicited by a therapeutic DC vaccine prevented an increase in integrated DNA after cART interruption.

355 HIV-1 Envelope Epitope Recognition Is Influenced by Immunoglobulin D_H Gene Segment Repertoire

Yuge Wang[2]; Aaron Sanchez-Silva[2]; Barton Haynes[1]; Harry Schroeder[2]

[1]Duke University, Durham, NC, US; [2]University of Alabama at Birmingham, Birmingham, AL, US; [3]University of Alabama at Birmingham, Birmingham, AL, US

Background: HIV-1-specific broadly neutralizing antibodies (BnAbs), such as the membrane proximal external region (MPER) antibodies 2F5 and 4E10, contain long H chain complementarity determining region 3 (CDR-H3) which is encoded by D_H gene segment, that lacks tyrosine and includes patches of hydrophobic and charged amino acids. However, B cells bearing Igs with charged or hydrophobic CDR-H3s are normally culled from mature B cell subsets. Thus, elucidation of mechanisms that underlie the difficulty in generating HIV-1 can be seen as a part of fundamental need to better understand how to distinguish self and non-self receptors that can neutralize pathogenic antigens without self-inflicting dame to the host.

Methods: Mice-BALB/c mice cohort limited to the use of single D_H gene segments were generated. ΔD-DFL is a human-like repertoire control. ΔD-DμFS promotes the use of hydrophobic amino acid CDR-H3. The ΔD-iD is charged amino acid enriched CDR-H3. **Immunization**-each strain of 10 mice was immunized with HIV-1 JR-FL gp140 protein. **Epitope Identification**-Two group of mice (No. 4 & 5) of each strain were selected (prior to immunization, and after the 2nd and 4th immunizations) for PEPperPRINT Chip to detect their epitopes on HIV-1 JR-FL gp140. **Serum Assay**-Binding ability was examined by HIV-1 envelope protein ELISA. Blocking activity was examined by competitive ELISA with soluble CD4 (sCD4) and 2F5, 2G12 antibodies.

Results: 1. We obtained evidence of strong and clear polyclonal responses to immunization with JR-FL gp140. As a general rule, the heterogeneity of the anti-JR-FL gp140 response varied by D_H genotype with ΔD-DFL>Wild Type (WT)>>ΔD-DμFS, ΔD-iD. Conversely, the intensity of the response was greatest in the ΔD-iD.

2. Linear response showed by PEPperPRINT chip was not identified with the response to natural HIV-1 epitopes, however, the ΔD-iD favored charged epitopes that is inconsistent with our hypothesis.

3. Anti-JR-FL gp140 antibodies present in the sera of the D_H altered did not block HIV-1 envelope CD4, 2F5, 2G12 binding site. This suggests reduced affinity, stability or on rates, or increased off rates for Igs obtained from D_H altered mice.

Fig1. D_H Altered Mice Cohorts and Immunization

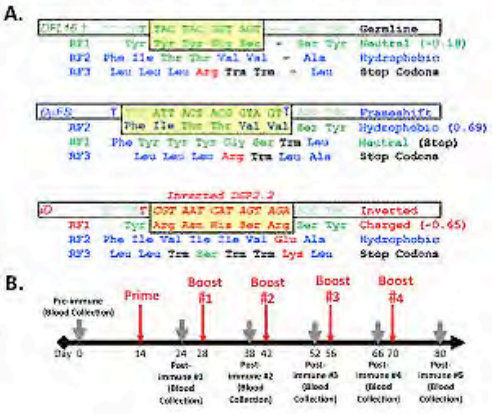

Fig3. Alteration of D_H Sequence Biases Anti-HIV-1 Linear Peptide Response Preference.

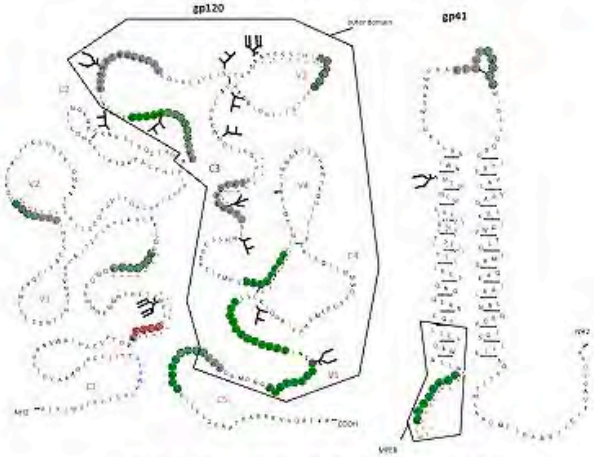

Fig2. Alteration of D_H Sequence Biases Anti-HIV-1 Gp160 Epitope Preference

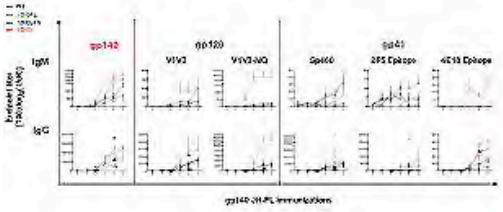

Fig4. D_H Altered Mice Shifts the Amino Acid Usage of Responding HIV-1 Epitopes

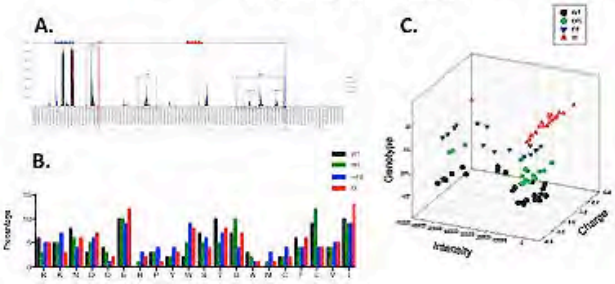

Conclusions: The pattern of epitope recognition and antigen binding in the response to HIV-1 JR-FL gp140, in part, is on D_H gene segment sequence. Restrictions imposed by natural selection of D_H sequence may underlie some of the difficulty that patients experience in HIV-1 neutralizing antibody.

356 Human Rhinovirus Displaying HIV-1 4E10 Epitope Elicits Broad Neutralization in hICAM-1 Tg Mice

Guohua Yi[1]; Xiongying Tu[2]; Preeti Bharaj[1]; Premlata Shankar[1]; Manjunath Swamy[1]

[1]Texas Tech University Health Sciences Center, El Paso, TX, US; [2]University of Minnesota, St Paul, MN, US

Background: Induction of bnAbs remains a critical goal towards developing a vaccine against HIV-1. We previously grafted 4E10 epitope of HIV-1 gp41 on the surface of human rhinovirus connected via linkers of varying lengths and sequences to construct combinatorial HRV display libraries. One chimeric HRV:HIV immunoselected from the libraries was able to elicit broad neutralization against 10 of 12 HIV-1 pseudoviruses in guinea pigs. However, guinea pigs do not get infected with HRV because they lack the viral receptor, human ICAM-1 and thus the antibody titers were rather modest. Since the recently developed hICAM-1 Tg mice support productive HRV infection, in this study we evaluated the efficacy of chimeric HRV:HIV vaccine in these mice.

Methods: hICAM Tg mice were intranasally immunized with three representative chimeric HRV:HIV viruses chosen from our previous study. The sera collected at different time points were tested for immunogenicity and HIV neutralization. ELISA was used to test the binding affinity against 4E10 peptide as well as HIV-1 gp140 trimer. The neutralizing ability against HIV-1 isolates was tested by single-round Tat-regulated luciferase assay in TZM-bl cells. Also, 11 HIV-1 internationally circulating isolates of diverse subtypes and coreceptor usages were used to test the breadth of neutralizing ability. HRV pre-immunized Tg mice were further immunized with chimeric HRV:HIV to test whether nasal administration can bypass HRV pre-immunity.

Results: The sera from the immunized mice showed good binding affinity with 4E10 peptide as well as with HIV-1 gp140 trimer. All three chimeric HRV:HIV elicited neutralizing antibody responses in hICAM-1 Tg mice against diverse isolates of HIV-1, with one eliciting anti-HIV antibodies capable of neutralizing 9 of the 11 internationally circulating HIV-1 isolates at IC50 level (from six subtypes and two co-receptor usages of HIV-1). Furthermore, intranasal administration of chimeric HRV:HIV could bypass the preexisting immunity to HRV to elicit anti-HIV response.

Conclusions: This work demonstrates that productive infection of HRV susceptible animals with chimeric HRV effectively elicits broadly neutralizing anti-HIV-1 antibodies. This strategy therefore appears to have potential for human vaccination.

357 WITHDRAWN

358 A Superagonist Antibody to Human Interleukin-21 Increases HIV-Specific T-Cell Function

Yew Ann Leong[1]; Yanfang Cui[1]; Zhian Chen[1]; Fiona Wightman[1]; Pellegrini Marc[2]; Jamie Rossjohn[1]; Sharon R. Lewin[3]; Alan Landay[4]; Charles Mackay[1]; Di Yu[1]

[1]Monash University/Alfred Hospital, Melbourne, Australia; [2]Walter and Eliza Hall Institution, Melbourne, Australia; [3]University of Melbourne, Melbourne, Australia; [4]Rush University Medical Center, Chicago, IL, US; [5]Monash University/Alfred Hospital, Melbourne, Australia

Background: Interleukin-21 (IL-21) is an immunostimulatory cytokine showing promising results in phase II clinical trials for cancer immunotherapy. IL-21 also enhances anti-viral immunity in HIV/SIV infections. It is a suitable candidate that can be targeted by the kick and kill strategy to boost immunity to eliminate HIV. This study focused on developing an agonistic monoclonal antibody (mAb) to human IL-21 (hIL-21) that enhances the anti-viral function of hIL-21.

Methods: A hIL-21-dependent Ba/F3 cell line proliferation assay was used to screen a library of anti-hIL-21 mAbs to identify agonistic clones. Binding of the agonist mAb to hIL-21 was characterized by Surface Plasmon Resonance (SPR) and crystallography. To test the anti-HIV function of the mAb, peripheral blood mononuclear cells (PBMCs; n=5) from HIV infected patients on antiretroviral therapy (ART>3 years, $CD4^+$ T-cell count>500/μL, viral load<50 copies/mL) were stimulated with MHC-I-restricted gag peptides in the presence of hIL-21 and the mAb. Cytotoxicity of natural killer (NK) and $CD8^+$ T cells were analyzed by measuring intracellular granzyme B and perforin expression by flow cytometry (FACS). The phamacokinetics and phamacodynamics of the mAb were studied in mice humanized with hIL-21 and the hIL-21 receptor (hIL-21R) and infected with lymphocytic choriomeningitis virus (LCMV). Bioavailability (BA) of hIL-21 with the mAb was measured by enzyme-linked immunosorbent assay. Agonistic effect of mAb was determined by quantifying virus-specific $CD8^+$ T-cell response by FACS and viral load by plaque assay.

Results: We identified a mAb SG1 that enhanced hIL-21's activity ≥10 folds in the Ba/F3 cell proliferation assay. It bound to hIL-21 with an affinity of 7.1E-11(K_D). Crystal structure and protein docking stimulation revealed that SG1 changed the conformation of hIL-21 to suit its binding to the receptor. In cultured PBMCs from HIV-infected patients, SG1 significantly increased the cytotoxicity of NK and $CD8^+$ T cells by 5-10 folds. In the chronic LCMV infection, SG1 increased the BA of hIL-21 >50 folds. An enhanced generation of functional virus-specific CD8+ T cells led to early resolution of the infection.

Conclusions: The high-affinity mAb SG1 has a unique function to enhance hIL-21's activity by changing its conformation and increasing the BA *in vivo*. Superagonist mAb SG1 promotes the anti-viral function of hIL-21 *in vitro* and *in vivo*. SG1 might be used in a kick and kill approach to eliminate HIV latency.

Cellular Immune Response to HIV

359 Evolution of HIV-Specific CD8+ T-Cell Responses in Hyperacute HIV Infection

Zaza M. Ndhlovu[1]; Nikoshia Mewalal[1]; Philomena Kamya[1]; Thandeka Nkosi[1]; Karyn Pretorius[1]; Nasreen Ismail[1]; Amber Moodley[2]; Krista Dong[2]; Thumbi Ndung'u[1]; Bruce Walker[2]

[1]University of KwaZulu-Natal, Durban, South Africa; [2]Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, US

Background: $CD8^+$ T cells suppress HIV replication, but the relationship to initial onset of plasma viremia has not been well defined since acute infections are rarely identified prior to peak viremia. Moreover, pre-infection samples are rarely available.

Methods: To address evolving viral and T cell dynamics from the onset of plasma viremia, hyperacute cases of HIV infection were identified by biweekly HIV RNA screening of plasma from high risk uninfected women in KwaZulu-Natal, South Africa, as part of a comprehensive HIV prevention program. Pre-infection and post infection blood samples were evaluated in 12 subjects identified with initial viral load as low as 140 RNA copies/ml plasma. Assays performed on fresh and/or cryopreserved cells included intracellular cytokine staining (Ki67, Bcl-2, CD38, HLA-DR, CD107a, IFN-g, TNF-a and IL-2) as well as IFN-g ELISPOT and class I tetramer staining.

Results: Onset of HIV viremia rapidly induced massive activation of CD8+ T cells from 0.27% (*IQR 0.87 to 0.88*) pre-infection to 52.7% (*IQR 41.8 to 67.4*) (*p<0.0001*), by day14 post onset of plasma viremia. In contrast, Influenza and CMV-specific CD8+ T cells were minimally activated, indicating that bystander activation was not occurring. HIV-specific responses were already detectable prior to peak viremia. Duration to highest frequency of activated T cells and the magnitude of the initial response both had a significant association with lower viral load set point (*time to peak activation, Spearman's r=0.7, p=0.02; magnitude at peak activation, Spearman's r=-0.7, p=0.02*). Stimulation with exogenously infected autologous CD4+ T cells revealed that at least 74% of the early proliferating CD8+ T cell response was HIV-specific with the capacity to degranulate and secrete cytokines. Acute phase HIV-specific CD8+ T cells were prone to apoptosis due to activation induced cell death but this resolved after viral load set point was achieved.

Conclusions: Our data provide strong evidence that the initial CD8+ T cell response to HIV is much larger than previously appreciated, but is highly proapoptotic and rapidly declines despite ongoing viremia. The rapidity and magnitude of the earliest response are key factors for successful control, as both inversely correlated with subsequent viral load set point. Overall, these studies suggest that, to facilitate long-term control, the initial CD8+ T cell response must be swift, of high magnitude and sustained.

360 Nonclassical Regulatory HIV-1–Specific CD8 T Cells in HIV-1 Disease Progression

Selena Vigano[2]; Chun Li[2]; Jordi J. Negron[2]; Bruce D. Walker[2]; Mathias Lichterfeld[1]; Xu G. Yu[2]

[1]*Massachusetts General Hospital, Boston, MA, US;* [2]*The Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, US*

Background: Regulatory T cells may influence HIV-1 disease progression by suppressing immune activation or inhibiting antiviral T cell immune responses. Recently, a distinct population of non-classical regulatory T cells expressing HLA-G was identified. However, the role of HLA-G-expressing T cells specific for HIV-1 is unknown.

Methods: 36 HIV-1-specific and 25 CMV/EBV-specific CD8 T cell responses were analyzed in 47 HIV-1 infected patients. 27 patients were chronic progressors with median HIV-1 viral loads of 50,300 copies/ml and median CD4 T cell counts of 456 cells/ul. 20 patients were controllers with viremia below 1000 copies/ml and CD4 T cell counts above 600 cells/ul. HLA-G expression on HIV-1 specific CD8 T cells was assessed by multimer staining and flow cytometry. Cytokine production of sorted HLA-G+ and non-regulatory CD8 T cells was assessed in 12 HIV-1 negative individuals following CD3/CD28 stimulation by Luminex.

Results: The frequency of HLA-G+ HIV-1 specific (*P*=0.0002), but not CMV- or EBV-specific (*P*=n.s) CD8 T cells, was increased in controllers when compared to chronic progressors. This increase was mostly driven by HLA-G+ CD8 T cells restricted by protective HLA class I alleles (*P*<0.004), while no difference between controllers and chronic progressors was observed when CD8 T cells restricted by non-protective alleles were analyzed. The proportion of HLA-G+ HIV-1-specific CD8 T cells was directly associated with CD4 T cell counts (*P*=0.0002, r=0.57) and inversely with viral loads (*P*<0.0001, r=-0.66), while total HIV-1-specific CD8 T cells were not. Of interest, HLA-G+ CD8 T cells produced higher amount of IL-10, IL-2, MIP-1α, MIP-1β and RANTES than HLA-G-negative CD8 T cells after anti-CD3/amti-CD28 stimulation.

Conclusions: These data indicate a potentially protective role of HIV-1-specific HLA-G+ regulatory CD8 T cells on HIV-1 disease progression. The production of MIP-1 α, MIP-1 β and RANTES may be pivotal in controlling HIV-1 replication. Further investigations of functional properties of these non-classical regulatory CD8 T cells are necessary in order to better elucidate their role in HIV immunopathogenesis.

361 Nef Plays a Role in the Resistance of SIV-Infected Macrophages to CD8+ T-Cell Suppression

Jennifer N. Rainho; Mauricio A. Martins; Francesc Cunyat; David I. Watkins; Mario Stevenson

University of Miami, Miami, FL, US

Background: SIV-specific CD8+ T cells kill SIV-infected CD4+ T cells in a MHC Class I (MHC-I) dependent manner. However, they are less efficient at killing SIV-infected macrophages. Since Nef has been shown to down regulate MHC-I molecules and enhance CTL evasion, we examined if Nef played a role in protecting SIV-infected macrophages from killing by freshly sorted SIV-specific CD8+ T cells.

Methods: The viral suppression assay (VSA) involves the co-culture of primary SIV-infected CD4+ T lymphocytes or monocyte-derived macrophages (target cells), with enriched, primary unstimulated SIV-specific CD8+ T cells (effector cells) for 24 hrs. Suppression of viral replication was determined by an antigen capture assay for Gag p27 in culture supernatants. Elimination of infected target cells was assessed by flow cytometric quantification of Gag p27+ target cells in the presence and absence of effectors. To explore the role of Nef in CD8+ T cell evasion, target cells were infected with wild type SIVmac239 (239wt-*nef*), *nef*-deleted SIVmac239 (239Δ*nef*), and a Nef point mutant (Y223F–*nef*) shown previously to inactivate the ability of Nef to down regulate MHC-I. Our controls included SIV-infected target cells in the absence of effectors and SIV-infected target cells isolated from animals with mismatched MHC-I alleles.

Results: Freshly sorted SIV-specific CD8+ T cells eliminated SIV-infected CD4+ T cells, but not SIV-infected macrophages (p=<0.0001). Suppression of viral replication was also observed in cultures of CD4+ T cells, but not in SIV-infected macrophage cultures (p=0.0031.) Interestingly, we observed enhanced killing of macrophages infected with 239Δ*nef* (p= 0.0276) compared to macrophages infected with wild type virus. The sensitivity of 239Δ*nef* -infected macrophages to CD8+ T-cell-mediated suppression was not fully recapitulated in Y223F–*nef*-infected macrophages despite the fact that the point mutant was almost as effective as Nef-deleted SIVmac239 in disrupting MHC-I down regulation.

Conclusions: SIV-infected macrophages evade CD8+ T cell suppression. Nef may be involved in the resistance of infected macrophages to CD8+ T-cell-mediated suppression. However, this protective effect cannot be fully explained by Nef's ability to down regulate MHC-I. This study has implications for viral persistence and suggests that macrophages may afford primate lentiviruses some degree of protection from immune surveillance.

362 Defining Efficacious HIV-Specific CTL Responses Using Saporin-Conjugated Tetramers

Ellen M. Leitman[1]; Stuart Sims[2]; Rebecca P. Payne[1]; Fabian Chen[3]; Lynn Riddell[4]; Soren Buus[5]; Steven Deeks[6]; Bruce Walker[7]; Philippa C. Matthews[1]; Philip J. Goulder[1]

[1]*University of Oxford, Oxford, United Kingdom;* [2]*ETH Zurich, Basel, Switzerland;* [3]*Royal Berkshire Hospital, Reading, United Kingdom;* [4]*Northamptonshire Healthcare NHS Trust, Northampton, United Kingdom;* [5]*University of Copenhagen, Copenhagen, Denmark;* [6]*University of California San Francisco, San Francisco, CA, US;* [7]*Ragon Institute of MGH, MIT and Harvard, Charlestown, MA, US*

Background: *In vitro* killing of HIV-infected cells by cytotoxic T lymphocytes (CTL) is a surrogate marker of CTL antiviral efficacy. Tetrameric peptide-MHC complexes (tetramers) enable identification of antigen-specific CD8+ T cells in a mixed population. Due to their rapid internalization by cognate T cells, tetramers are an effective delivery vehicle of any coupled moiety to target specific CTL. Novel tetramers conjugated to saporin (SAP), a potent toxin causing cell death through ribosome-inactivation, have been used *in vivo* to deplete murine diabetogenic T cells, but no human reports exploiting this technology exist to date. Here, we used toxic tetramers to rapidly eliminate or 'zap' human CTL of different specificities in order to compare their anti-HIV potency.

Methods: PBMC were treated with HLA-matched SAP-coupled tetramers (tet-SAP) or a control (HLA-matched tet-PE, HLA-mismatched tet-SAP, free SAP) and cell loss was quantified by flow cytometry. In inhibition assays, CD8+ T cells were expanded, treated with tet-SAP or a control and added as effectors to HLA-matched target cells infected with NL4-3-GFP, used as a marker to measure viral inhibition.

Results: We show that HLA-matched tet-SAP but not HLA-mismatched tet-SAP or free SAP selectively binds to the surface of antigen-specific CD8+ T cells and is then rapidly internalized by the cognate cells alike a conventional tet-PE of the same specificity. We further show that, by as little as 48h post-tet-SAP treatment, up to 97% of tetramer-specific cells are eliminated from the diverse CTL population (Fig 1A). This elimination is highly targeted pertaining exclusively to the desired specificity. Finally, we compare the abilities

of zapped, untreated or control-treated CTL to inhibit viral replication, using CD8+ T cells from an HLA-B*27:05+ controller with the dominant B*27:05-Gag-KK10 response. We observe that untreated bulk and control-treated CD8+ T cells effectively inhibit viral replication, but zapped CTL lacking KK10-specific cells lose this suppressive capacity (Fig 1B).

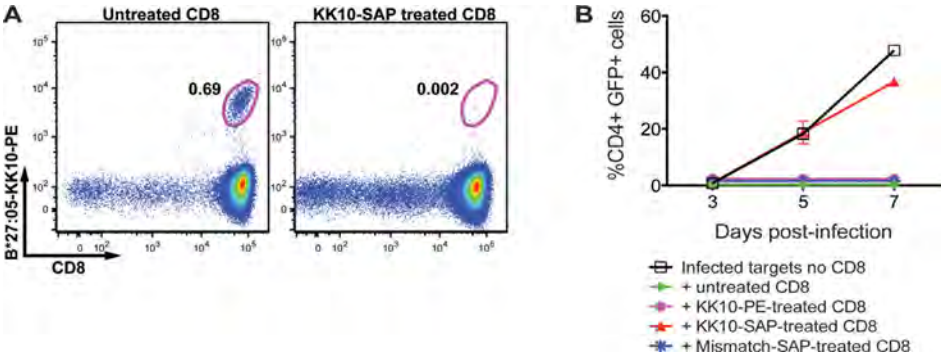

Figure: (A) Representative FACS plots showing HLA-B*27:05-KK10+ CD8+ T cells in an HIV+ subject (left) and their elimination 48h after KK10-SAP treatment (right). Numbers indicate %liveCD3+CD8+tetramer+ cells. **(B)** Viral inhibition assay showing loss of the suppressive capacity by KK10-zapped cells.

Conclusions: We have optimized a novel method to eliminate CTL of different specificities and thereby measure their individual contribution to viral suppression. This rapid, efficient, cost-saving method, applicable to any HLA type, will enable us to discriminate between the most efficacious and futile CTL responses in HIV infection and answer the long-standing question of the quality of different responses – the holy grail of a therapeutic HIV vaccine research.

363 Linking Pig-Tailed Macaque Major Histocompatibility Complex Class I Haplotypes and Cytotoxic T Lymphocyte Escape Mutations in SIV Infection

Shayarana Gooneratne[1]; Hamid Alinejad-Rokny[2]; Diako Ebrahimi Mohammadi[2]; Patrick Bohn[3]; Roger Wiseman[3]; David O'Connor[3]; Miles Davenport[2]; Stephen Kent[1]

[1]University of Melbourne, Melbourne, Australia; [2]University of New South Wales, Kensington, Australia; [3]University of Wisconsin Madison, Madison, WI, US

Background: Cytotoxic T lymphocytes select for virus escape mutants of HIV and SIV and this limits the effectiveness of vaccines and immunotherapies against these viruses. The influence of MHC-I alleles on HIV diversity has been well characterised in humans at the population level. MHC-I alleles likely affect viral diversity in the SIV-infected pig-tailed macaque (*M. nemestrina*) model, but this is poorly characterised. We studied the evolution of SIV in pig-tailed macaques with a range of MHC-I haplotypes.

Methods: SIVmac251 genomes were amplified from the plasma of 44 pig-tailed macaques infected with SIVmac251 at 4-10 months after infection and characterized by Illumina deep sequencing. MHC-I typing was performed on cellular RNA using Roche/454 pyrosequencing. MHC-I haplotypes and viral sequence polymorphisms were linked using in-house bioinformatics pipelines, both at individual mutations and groups of mutations spanning 10 amino acid segments, since CTL escape can occur at different amino acids within the same epitope in different animals.

Results: The approach successfully identified 6 known CTL escape mutations within 3 Mane-A1*084-restricted epitopes. The approach also identified over 70 new SIV polymorphisms linked to a variety of 32 MHC-I haplotypes. Using functional CD8 T cell assays we confirmed that one of these associations, a Mane-B028 haplotype-linked mutation in Nef, corresponded to a CTL epitope. We also identified mutations associated with the Mane-B017 haplotype that were previously described as CTL epitopes restricted by *Mamu-B*017:01* in rhesus macaques.

Conclusions: Patterns of immune escape variants are similar in HIV-1 infected human subjects that share the same MHC-I genes, but this has not been studied for SIV infection of macaques. By studying SIV sequence diversity in 44 MHC-typed SIV-infected pig-tailed macaques, we defined over 70 sites within SIV where mutations were common in macaques sharing particular MHC-I genes. Further, pig-tailed macaques sharing near-identical MHC-I genes with rhesus macaques responded to the same CTL epitope and forced immune escape. This allows many reagents developed to study rhesus macaque reagents to also be used to study pig-tailed macaques. Overall, our study defines sites of immune escape in SIV in pig-tailed macaques and this enables a more refined level of analysis of future vaccine design and treatment strategies for HIV.

364 HLA Class-II–Associated HIV Polymorphisms Predict Escape From CD4 T-Cell Responses

Nathaniel B. Erdmann[1]; Victor Du[1]; Jonathan M. Carlson[2]; John Sidney[3]; Ling Yue[4]; Susan Allen[4]; Eric Hunter[4]; Sonya L. Heath[1]; Anju Bansal[1]; Paul A. Goepfert[1]

[1]University of Alabama at Birmingham, Birmingham, AL, US; [2]Microsoft Research, Los Angeles, CA, US; [3]La Jolla Institute of Allergy and Immunology, La Jolla, CA, US; [4]Emory University, Atlanta, GA, US

Background: Human immunodeficiency virus (HIV) can escape antiretroviral therapy, antibody and CD8$^+$ T-cell pressure indicating these factors assist in viral control. The ability of CD4$^+$ T-cells to force escape mutations and influence HIV-1 viral control remains unclear.

Methods: We applied a computational approach to identify HIV polymorphisms (adaptations) in *gag*, *pol*, and *nef* disproportionately associated with specific HLA-II alleles in an African cohort of chronically infected individuals. Peptides including the predicted adaptation (AE) or a non-adapted version of the epitope (NAE) were synthesized and evaluated for immunogenicity. We applied a CD8$^+$-depleted interferon-γ ELISpot assay using PBMC obtained from chronically infected donors that were non-controllers (viral load >10,000 copies/mL), controllers (viral load <2,000 copies/mL) or acutely infected individuals. We determined the immunogenicity of predicted epitopes relative to dominant viral sequence in chronic infection, as well as transmitted founder virus (TFV) in acute HIV infection (AHI).

Results: We identified 29 HLA class-II associated HIV adaptations, all of which were demonstrated to represent novel CD4$^+$ T-cell epitopes. Consistent with a prior study, magnitude and breadth of HIV-specific CD4$^+$ T-cell responses seen in controllers was higher as compared to non-controllers. The magnitude of responses to epitopes containing the adapted polymorphism (AE) was lower when compared to NAE (p=0.0009). Even when the dominant viral sequence matched the predicted AE in chronic infection, NAE were more immunogenic (p=0.01). We studied a cohort of individuals with AHI to more clearly delineate the epitope responsible for observed immune responses. We found a relative lack of AE-specific CD4$^+$ T-cell responses (p=0.008) despite the TFV encoding equal numbers of AE and NAE. Longitudinal data from AHI individuals followed for 1-2 years off antiretroviral therapy demonstrated sequence changes at predicted epitopes that were biologically confirmed to represent CD4$^+$ T-cell mediated escape.

Conclusions: These data demonstrate the identification of HLA-II associated polymorphisms as a means to identify novel CD4$^+$ epitopes. In addition, our studies in acute and chronic infection definitively characterize HIV escape from CD4 T-cell responses, a phenomenon that is more common than previously anticipated. Our findings emphasize the importance of inducing CD4$^+$ T-cells along with CD8$^+$ T-cells and antibodies as part of a comprehensive HIV vaccine strategy.

365 Rapid Construction of HIV-1-Specific T Cell Receptor Gene Therapy Lentiviral Vectors

Background: HIV-1-specific CD8$^+$ cytotoxic T lymphocytes (CTL) can play an important role in the long-term control of HIV-1 replication *in vivo*. Unfortunately, most HIV-1-infected persons are unable to control the virus with their T cell receptor (TCR) repertoire, due to inadequate coverage of epitope variation. A potential immunotherapeutic strategy for a functional cure could be the adoptive transfer of gene-modified T cells, equipped with a combination of TCRs covering all common variants of their targeted epitope. We developed a rapid methodology to identify epitope-specific TCR sequences and insert them into lentiviral vectors without need for HLA tetramers, cell sorting, or cell cloning.

Methods: We focused on five HIV-1 Gag epitopes based on common or protective HLA type and epitope conservation: KRWIILGLNK$_{263-272}$ (KK10, HLA-B*2705), KAFSPEVIPMF$_{162-172}$ (KF11, B*5701), GLNKIVRMY$_{269-277}$ (GY9, B*1501), RQANFLGKI$_{429-437}$ (RI9, B*1302), and WASRELERF$_{36-44}$ (WF9, B*3501). Using a quantitative spectratyping method, we directly identified Gag-specific TCR sequences by expansion after epitope stimulation. Both TCR α and β chains were cloned in a one step reaction into a lentiviral vector. The functionality of these TCRs was examined through a Jurkat cell NFAT-dependent GFP reporter assay and also chromium release assays with transduced primary CD8$^+$ T cells against HIV-1-infected T1 cells transduced with the relevant HLA genes. Panels of HIV-1 NL4-3 with common epitope variants were generated by point mutagenesis.

Results: We cloned and functionally confirmed sixteen TCRs (seven for KK10, four for KF11, three for GY9, one for RI9, and one for WF9). Several TCRs have been screened for their recognition of epitope variants and functional avidity using synthetic peptides, and will be screened for their antiviral activity against cells infected with HIV-1 containing these variants.

Conclusions: Our data demonstrate proof-of-concept for rapid TCR cloning into vectors suitable for gene therapy and capacity to screen these TCRs for ability to recognize epitope variants. This sets the foundation for combination TCR gene therapy to cover epitope variation.

366 The Role of Exosomes in Semen in Suppressing Natural and Vaccine-Induced Immunity

Lucia Vojtech; Sean Hughes; Claire Levy; Florian Hladik
University of Washington, Seattle, WA, US

Background: Exposure to semen is the primary route of transmission for many sexually transmitted infections, including HIV. Accumulating evidence suggests that components in semen directly impair leukocytes, which could compromise the protective efficacy of vaccine-induced immune responses in the mucosa. Seminal plasma contains large numbers of extracellular microvesicles or exosomes (SE). Exosomes in general have been identified as important mediators of intercellular communication and immunoregulation. Thus, we explored the effects of SE on recipient blood and mucosal immune responses.

Methods: SE isolated from semen donated by healthy men were pooled from multiple donors. Dendritic cells (DCs) were derived from peripheral blood mononuclear cell (PBMC) monocytes. DCs and PBMC cultures were exposed to SE and assayed for SE uptake, immune function, and cytokine production by confocal microscopy, flow cytometry, Luminex, and quantitative PCR.

Results: Extracellular vesicles from semen are present at an average concentration of 2.2 x 10^{13} particles per ejaculate (n = 18 donors). These SE rapidly and efficiently entered peripheral and vaginal dendritic cells (DCs), more slowly entered B and CD4+ T cells, and only poorly entered CD8+ T cells. In PBMC cultures, SE impaired memory T cell function, reducing the production of TNF-alpha and/or IFN gamma in response to CMV, EBV, or influenza-derived peptides an average of 73% for CD4+ T cells and 55% for CD8+ T cells, in a dose-responsive manner (n = 4 donors). SE also impaired vaginal T cell responses to a superantigen. Exposing only DCs, as opposed to bulk PBMCs, to SE also blocked subsequent CD8+ memory T cell activation, reducing the proportion of cells making cytokines by 51% (n = 3 donors). This effect occurred even when only a fraction of DCs (as low as 20%) were exposed to SE. SE also impaired the innate immune response of monocytic THP-1 cells stimulated by bacterial lipopolysaccharide: cytokine production was reduced at both the mRNA level and the protein level.

Conclusions: SE inhibit a broad range of both innate and adaptive immune responses. CD4+ T cells appear to be directly affected, while CD8+ T cell function is impaired by affecting the co-stimulatory capacity of antigen-presenting cells. Understanding how programmed immune responses are altered by the presence of semen is important to developing the next generation of vaccines and preventative treatments against sexually transmitted diseases.

367 IFN-alpha Stimulated NK Lysis of HIV-Infected CD4$^+$ T Cells Requires NKp46 and NKG2D

Costin Tomescu[1]; Domenico Mavilio[2]; Luis J. Montaner[1]
[1]*The Wistar Institute, Philadelphia, PA, US;* [2]*Humanitas Clinical and Research Center, Milan, Italy*

Background: Interferon-alpha (IFN-alpha) is a potent clinical immuno-modulatory agent with the capacity to limit viral replication and stimulate NK activity against virally infected target cells. We have previously shown that NK lysis of HIV-1 infected autologous CD4$^+$ primary T cells requires *exogenous* IFN-alpha stimulation. Here, we identify the specific activating receptor(s) involved in HIV-1 infected target cell lysis by autologous NK cells activated *endogenously* with IFN-alpha.

Methods: Purified CD4$^+$ primary T cells were HIV-1 infected and used to stimulate IFN-alpha secretion from autologous PBMC. NK cell-mediated cytotoxicity was measured with a 4 hour chromium release assay in the presence or absence of neutralizing monoclonal antibodies against 2B4, NTB-A, NKG2D, NKp30, NKp44, and NKp46. Comparisons of three or more paired groups was carried out using a Friedman test adjusted with post-hoc analyses of two groups by a Wilcoxon signed-rank test.

Results: Direct recognition of HIV-1 infected target cells by autologous PBMC led to the secretion of significant amounts ($p<0.001$) of IFN-alpha by Plasmacytoid Dendritic Cells. *Endogenous* IFN-alpha stimulation led to strong NK activation as detected by CD69 upregulation and triggered NK lysis of HIV-1 infected autologous CD4$^+$ primary T cells ($p<0.01$). IFN-stimulated NK cell lysis of HIV-1 infected CD4$^+$ primary T cells was significantly decreased in the presence of neutralizing antibodies against NKp46 ($p<0.01$) and NKG2D ($p<0.05$) while NKp30, NKp44, 2B4 and NTB-A were not required.

Conclusions: The NKp46 and NKG2D activating NK cell receptors are required for NK lysis of HIV-1 infected autologous CD4$^+$ primary T cells following IFN-alpha stimulation. The anti-viral mechanisms of action of IFN-alpha against HIV-1 may in part be due to NK-mediated clearance of HIV-1 infected target cells via the NKp46 and NKG2D receptors.

Immune-Based Strategies in Latency

368 Stimulation of Broad CTL Response Is Required to Clear Latent HIV-1 in Humanized Mice

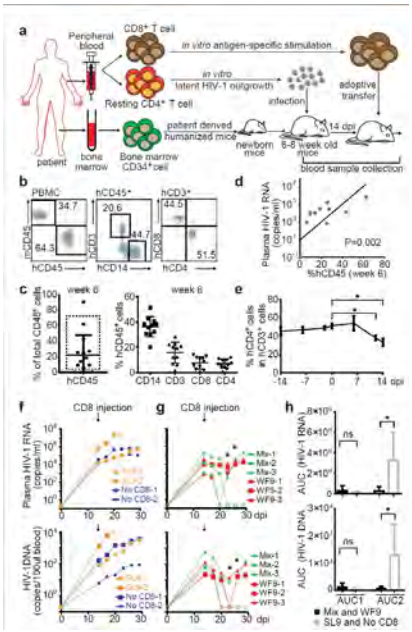
Liang Shan[1]; Kai Deng[2]; Richard Flavell[1]; Robert F. Siliciano[2]

[1]*Yale University, New Haven, CT, US;* [2]*Johns Hopkins University School of Medicine, Baltimore, MD, US*

Background: Despite antiretroviral therapy (ART), HIV-1 persists in a stable latent reservoir, primarily in resting memory CD4$^+$ T cells.To purge the reservoir, pharmacological reactivation of latent HIV-1 has been proposed and tested both *in vitro* and *in vivo*. The next step is to eliminate the resting CD4$^+$ T cells in which latent HIV-1 has been induced through virus-specific immune mechanisms including cytolytic T lymphocytes (CTL). However, the vast majority (>98%) of latent viruses in chronic patients carry CTL escape mutations that render the infected cells insensitive to CTLs directed at common epitopes, such as SL9 epitope in HLA-A2-positive patients.

Methods: To test whether CD8$^+$ T cells from patients under ART are able to recognize and clear latent HIV-1, we generated patient-derived humanized mice using a recently reported mouse system named MISTRG. With humanization by knockin replacement of the *Csf1*, *Csf2, Il3, Tpo* and *Sirpa* genes in the *Rag2*$^{-/-}$ *Il2rg*$^{-/-}$ genetic background, MISTRG mice are highly permissive for human hematopoiesis and support the reconstitution of robust human lymphoid and myelomonocytic systems. We infected patient-derived humanized mice with primary HIV-1 isolates grown from resting CD4$^+$ T cells of the same patient and then evaluated antiviral effect of autologous CD8$^+$ T cells.

Results: MISTRG mice engrafted with HLA-A2-positive patient bone marrow CD34$^+$ cells successfully developed human T-lymphocyte and monocyte/macrophage subsets, which were sufficient to support HIV-1 infection. In control mice or mice that received autologous patient CD8$^+$ T cells pre-stimulated with the common epitope SL9, levels of plasma HIV-1 RNA and proviral DNA in PBMCs continued to increase from day 14 to day 29 after infection. In sharp contrast, 100- to 1,000-fold decreases in plasma HIV-1 RNA levels were observed in all mice that received patient CD8$^+$ T cells pre-stimulated with the mixture of Gag peptides including unmutated epitopes.



Broad-spectrum cytotoxic T lymphocytes suppress in vivo infection of patient-derived humanized mice with autologous latent HIV-1**.**

Conclusions: Our results demonstrate that chronically infected patients retain a broad spectrum viral-specific CTL response which is sufficient to inhibit in vivo replication of HIV-1 isolated from latent reservoir. These results suggest that latent HIV-1 can be eliminated in chronically infected patients despite the overwhelming presence of CTL escape variants. Directing efficient CTL responses to unmutated viral epitopes is essential to the clearance of latent HIV-1.

369 *In vivo* effects of Panobinostat and Romidepsin on HIV-1-specific CD8 T Cell Immunity

Rikke Olesen[1]; Thomas A. Rasmussen[1]; Mathias Lichterfeld[2]; Mette E. Graversen[1]; Steffen Leth[1]; Lars Østergaard[1]; Ole S. Søgaard[1]; Martin Tolstrup[1]

[1]*Aarhus University Hospital, Aarhus, Denmark;* [2]*Ragon Institute of MIT, MGH and Harvard, Boston, MA, US*

Background: We recently showed that the histone deacetylase inhibitors (HDACi) panobinostat (PANO) and romidepsin (ROMI) activates HIV-1 from latency in HIV-1 infected patients on antiretroviral therapy (ART). However, concern has been raised that HDACi may diminish effector functions of CD8 T cells, thus impairing the elimination virus-expressing cells. Here, we evaluated HIV-1-specific CD8 T cell responses during clinical administration of PANO and ROMI.

Methods: In two separate clinical trials, PANO (20 mg per dose) or ROMI (5mg/m^2 per dose) were administered to virologically suppressed HIV-1 infected adults on ART. In 14 of 15 PANO-treated and 6 of 6 ROMI-treated patients, cryo-preserved PBMCs isolated pre-HDACi (baseline), on-HDACi, and post-HDACi (follow-up) were analyzed by intracellular cytokine staining (ICS) following stimulation with a HIV-1 Gag peptide pool. Cells were labelled with Near-IR amino reactive dye, surface antibodies (CD4, CD8, CD45RA and CCR7) and IFNγ (ICS) and analyzed on a BD FACSVerse cytometer. Comparisons were performed using Wilcoxon matched-pairs test.

Results: We observed no overall statistical significant changes in total CD8 T cell counts before and after PANO or ROMI treatment. However, during PANO treatment the relative composition of CD8 T cell subsets changed significantly with increased proportions of effector memory (EM) (p=0.005) and central memory CD8 T cells (p=0.03); and decreased proportions of naïve CD8 T cells (p=0.04). These changes had returned to pre-HDACi levels at follow-up. During ROMI treatment we saw no statistical significant change in the CD8 T cell memory subset composition. The majority of HIV-specific cells in all subjects were EM CD8 T cells. In 11 of 14 (79%) PANO-treated patients and 5 of 6 (83%) ROMI-treated

patients, we detected IFNγ+ HIV-specific EM CD8 T cells. In these patients, the mean IFNγ+ HIV-specific EM CD8 T cell responses were 0.80% (range 0.12-2.39%) and 0.95% (range 0.86-4.32%) at baseline for PANO- and ROMI-treated subjects, respectively. The frequency of IFNγ+ HIV-specific EM CD8 T cell responses did not change during PANO (p=0.7) or ROMI (p=0.1) treatment or at follow-up (PANO p=0.7, ROMI p=0.8).

Conclusions: In two clinical trials, treatment of HIV-1 infected patients with PANO or ROMI did not decrease the levels of HIV-1-specific EM CD8 T cells. These results provide support for the combination of HDACi and immune-based therapies in HIV-1 eradication trials.

370 Vaccine Induced Follicular CD8 T Cells Enhance Control of Pathogenic SIV Infection

Geetha H. Mylvaganam; Daniel Rios; Gregory Tharp; Steven Bosinger; Vijayakumar Velu; Rama R. Amara
Emory University, Atlanta, GA, US

Background: Recent data demonstrated that a significant fraction of latently-infected cells reside in the germinal center (GC) resident T follicular helper cells (Tfh) during HAART of HIV-infected humans/SIV-infected macaques. Therapeutic interventions aimed at achieving a functional cure must target these viral reservoirs. Induction of highly functional anti-viral CD8 T cells that can home to GC (follicular CD8) represents an attractive therapeutic strategy. However, GCs are generally thought to exclude CD8 T cells and very little is known about whether T cell based vaccines induce anti-viral CD8 T cells with the potential to migrate to the GC and influence HIV/SIV replication in Tfh. Here, we addressed this in the context of DNA/MVA vaccination and pathogenic SIV infection in rhesus macaques (RM).

Methods: RM were vaccinated with our DNA/MVA SIV vaccine with and without adjuvants and challenged intrarectally with SIVmac251. Follicular CD8 T cells were identified based on the expression of chemokine receptor CXCR5 (B cell follicle homing potential) on Gag CM9 tetramer+ CD8 T cells (Tet+).

Results: Following vaccination, a small fraction (<10%) of Tet+ CD8 T cells in blood expressed CXCR5. However, following SIV infection, the frequency of Tet+ CXCR5+ CD8 T cells in blood and LN increased dramatically as early as 2 weeks post infection, were present at high levels even at 24 weeks (about 40% of Tet+ in LN) and correlated directly with their frequency post vaccination. These Tet+ CXCR5+ cells were not present in unvaccinated SIV infected animals although Tet+ cells were present. Importantly, among the vaccinated animals the frequency of Tet+ CXCR5+ CD8 T cells in blood at 2 weeks post infection was strongly associated with enhanced viral control both at peak and set point. Immunofluorescence staining of both rectal and LN tissues from vaccine controllers revealed co-localization of CD8 T cells with Tfh in GC. Impressively, the CXCR5+ CD8 T cells from the controller RM restricted the anti-CD3 driven expansion of CM9 peptide pulsed Tfh cells in vitro suggesting their killing potential. Transcriptome analysis of purified CXCR5+ Tet+ CD8 T cells identified these cells as a unique multi-faceted population expressing genes associated with both CTLs and Tfh subsets.

Conclusions: Our results demonstrate that it is possible to elicit follicular CD8 T cells by vaccination and these cells contribute significantly to the control of SIV infection. These findings have implications for cure strategies against HIV.

371 Blockade of PD-L1 Does Not Reverse HIV Latency in CD4+ T Cells Ex Vivo

Elizabeth Fyne[1]; Shalyn Campellone[2]; Huilin Qi[2]; Amy Sheaffer[2]; Stephen Mason[2]; John W. Mellors[1]
[1]*University of Pittsburgh, Pittsburgh, PA, US;* [2]*Bristol-Myers Squibb Co., Wallingford, CT, US*

Background: Blockade of the PD-1/PD-L1 pathways using monoclonal antibodies (mAb) to PD-1 has been reported to activate HIV expression from latently infected CD4 T cells ex vivo. To further evaluate this approach, we tested the ability of the human anti-PD-L1 mAb BMS-936559 to activate virion production from mononuclear cells obtained from patients on suppressive ART.

Methods: PBMC, total (t) CD4, and resting (r) CD4 cells were purified by negative selection of large-volume blood draws from HIV-infected donors. Freshly isolated PBMCs were cryopreserved and immunophenotyped for PD-1/PD-L1 expression. The remaining cells were incubated (1 million cells/well in triplicate) for 1 week with 20, 5, or 1.25μg/ml anti-PD-L1 mAb, with 20μg/ml isotype control [Zymogen DT-1D12g-4P (hIgG4)], or with anti-CD3/CD28-coated microbeads plus either anti-PD-L1 mAb or isotype control. On Day 8, cells were assessed for viability and supernatants tested for HIV RNA using the Roche Taqman v.2.0. A virologic response was defined as a >3-fold increase in HIV RNA over isotype control. Donors whose cells responded initially to anti-PD-L1 mAb were redrawn and tested again.

Results: PBMC, tCD4, and rCD4 cells purified from ten long-term (mean 8 years) suppressed donors. Cell viability was not reduced by treatment with anti-PD-L1 mAb. 9 of 10 donors responded to anti-CD3/CD28 in all cell types (mean fold-increases of 742, 1353, and 272 for PBMC, tCD4 and rCD4, respectively). Anti-PD-L1 mAb did not enhance responses to anti-CD3/CD28. PBMC from 2 of 10 donors (donor 3: 61-fold; donor 4: 7-fold) showed an initial response to anti-PD-L1 mAB that was not reproduced upon repeat blood draw. tCD4 cells from 2 of 10 donors (donor 2: 583-fold; donor 6: 84-fold) initially responded to anti-PD-L1. However, cells from donor 2 did not respond after a repeat draw. Cells from donor 6 responded on the first repeat draw but not the second. rCD4 from 0 of 10 donors responded to anti-PD-L1. PD-1/PD-L1 expression on CD4 and CD8T cells was evident on the day of cell isolation in all donors, but expression levels did not differ between responders, non-responders, and a healthy control.

Conclusions: Despite detectable PD-1/PD-L1 expression, increased HIV production from PBMC, total CD4 T cells or resting CD4 T cells after treatment with anti-PD-L1 antibody was infrequent and not reproduced longitudinally. Alternate strategies will be needed to activate proviral expression from latently infected CD4 T cells.

372 Impact of HIV Latency Reversing Agents on Natural Killer Cells

Carolina Garrido; Julia Sung; Swati Gupta; Katherine Sholtis; Nancie Archin; David Margolis
Medicine, University of North Carolina
University of North Carolina, Chapel Hill, NC, US

Background: Eradication of HIV infection requires unmasking of the HIV latent reservoir using latency reactivating agents (LRAs) and the implementation of an immune response to clear infected cells. Thus, an assessment of the impact of LRAs immune function is required. We evaluated the effect of LRAs on natural killer cells (NKs).

Methods: Five LRAs were evaluated: 3 histone deacetylase inhibitors, SAHA, Romidepsin (RMD) and Panobinostat (PNB); and 2 protein kinase C activators, Prostratin (PRT) and Ingenol (ING). Each drug was tested at 3 concentrations (cc): physiological, lower and higher. NKs from 3 HIV-negative donors were isolated and exposed 24h to the LRAs and washed out. NKs viability was assessed by AnnexinV+7AAD staining. Cytotoxicity was evaluated through degranulation upon culture with K562 cells, measuring %$CD56^+CD107a^+$cells. Antiviral activity was measured in a viral inhibition assay using autologous $CD4^+$T cells infected with JR-CSF and quantifying p24 at day 7 of culture.

Results: Table 1 shows results for LRAs treatment at physiological concentration. RMD, PNB and PRT showed significant toxicity on NKs. Of note, SAHA and ING did not increase cell death at any cc, while PNB produced significant cell death even at lower cc (5nM) (261.9% (63.8)). RMD, PNB and ING at physiological cc reduced significantly degranulation, and we observed an increase of both viability and degranulation impairment at higher cc (100, 100 and 1000 nM, respectively) of these drugs. Viral inhibition assays showed that any cc of SAHA impair antiviral activity, while RMD impaired it significantly at physiological and lower cc (68.8%(10.6)). Interestingly, ING had a bimodal effect, impairing viral inhibition (28.6% (9.5)) at low cc but improving it at higher cc (183.2% (91.1)). All other conditions did not produce statistically significant differences compared to untreated NKs, but we observed that PRT did not impair viral inhibition while PNB at physiological cc reduced NK antiviral effect to 37.46% (40.72).

	Untreated NKs	SAHA (335 nM)	RMD (10 nM)	PNB (20 nM)	PRT (1000 nM)	ING (100 nM)
AnnexinV+7AAD+	100	123.1 (14.5)	192.9* (35.3)	261.9* (63.8)	114.7* (6.6)	95.9 (3.7)
CD56+CD107a+	100	103.1 (2.3)	80.0* (2.5)	55.8* (3.1)	86.8 (4.5)	66.6* (7.1)
% HIV inhibition	100	131.1 (14.23)	35.9* (8.54)	37.46* (23.51)	110.26 (27.81)	51.93* (21.11)

Table 1. Toxicity, degranulation and antiviral activity of NKs treated with the different LRAs at physiological concentration, compared to NKs without treatment. Mean (SEM). * indicates significance (p<0.05, paired t test)..

Conclusions: RMD and PNB impaired viability, cytotoxicity and antiviral activity of NKs at physiological concentrations. PRT and ING had a modest effect on NK function. SAHA did not show any effect on NKs at the tested concentrations. This in vitro data indicates that some LRAs can impair NK immune function, and thus could have an impact on viral clearance after reactivation. However, in vivo testing is warranted to fully understand how these LRAs impact in the immune system when all components are present.

Viral Reservoir Dynamics During ART

373 The Earlier cART Is Initiated During PHI, the More Intracellular HIV-DNA Decreases

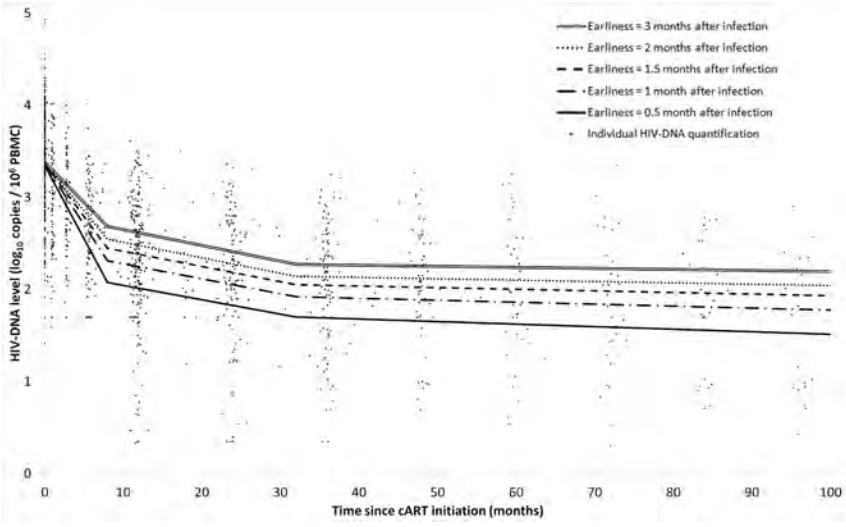
Moussa Laanani[2]; Jade Ghosn[1]; Asma Essat[2]; Adeline Mélard[3]; Rémonie Seng[2]; Emmanuel Mortier[4]; Cécile Goujard[2]; Laurence Meyer[2]; Christine Rouzioux[3]
On behalf of the ANRS PRIMO Cohort Study Group

[1]APHP, Hôtel Dieu University Hospital, Paris, France; [2]APHP, Bicêtre Hospital, Le Kremlin-Bicêtre, France; [3]APHP, Necker Hospital, Paris, France; [4]APHP, Louis Mourier Hospital, Colombes, France

Background: During the earliest weeks of primary HIV infection (PHI), HIV establishes a reservoir mainly in CD4+ T cell subsets. Combined antiretroviral therapy (cART) initiation during PHI yielded better immune restoration and larger decrease in cell-associated HIV-DNA than initiation during the chronic phase. In macaques, the reduction of SIV-DNA reservoir under cART was greater when initiated between 7 and 10 days than between 10 and 42 days after infection. Our objective was to model the short- and long-term decay of the cell-associated HIV-DNA blood reservoir in patients initiating cART during PHI and to assess the impact of the earliness of cART initiation on HIV-DNA level decay.

Methods: We included patients enrolled during primary HIV-1 infection in the multicenter ANRS PRIMO cohort, treated within the month following enrollment and achieving sustained virological response (HIV-RNA <50 cp/mL) as from Month 6. The decay of cell-associated HIV-DNA over time while on successful cART was modeled with a 3-slope linear mixed-effects model.

Results: 327 patients were included, accounting for 1,305 HIV-DNA quantifications**.** Median time between infection and cART initiation was 41 days (IQR: 33-54), and median follow-up under uninterrupted cART was 2.3 years (range: 0.4-16.6). The impact of the earliness of cART initiation was statistically significant on the first slope ($p<0.0001$): the earlier cART was initiated after HIV infection, the faster the HIV-DNA level decreased during the first 8 months of cART: -0.171, -0.131, and –0.068 $\log_{10}$ copies/10^6 PBMC /month when cART was initiated 15 days, 1 month, and 3 months after infection, respectively. The HIV-DNA level continued to decrease significantly under cART after Month 8 but with a lower steepness, and the second and third slopes were similar regardless of cART initiation earliness. The predicted mean HIV-DNA level achieved after 5 years of uninterrupted successful cART was 1.62 $\log_{10}$ copies/10^6 PBMC when cART was initiated 15 days after infection, and 2.24 $\log_{10}$ copies/10^6 PBMC when cART was initiated 3 months after infection ($p=0.0006$). Similar impact of cART earliness on HIV-DNA decrease was found when using the number of antibodies on western blot assay performed at cART initiation as a measure of precocity.



Slopes of decay of HIV-DNA under uninterrupted cART with successful virological response (<50 copies/ml from 6 months) predicted by a mixed-effects model, according to cART initiation earliness from HIV infection: the ANRS PRIMO cohort (327 patients, 1,305 measurements)

Conclusions: This study provides strong arguments in favor of cART initiation at the earliest possible time point after HIV infection. It also adds further weight for promoting early HIV diagnosis.

374 Decay Rate and HIV-1 DNA Reservoir Size Following Early Infant Antiretroviral Therapy
